The discussion so far has centered on barriers, both industry-systemic and technical, that impede the development, application, and deployment of new smart-building algorithms and technologies. However, many of these barriers can be overcome by adapting smart control and operational management methods to the unique aspects of the buildings industry; for example, the problem of too few sensors can be addressed by using models to predict measurements to create virtual sensors based on analytical redundancy. Signal processing methods can be used to reconstruct quantized data, and robust control theory can be used to minimize the effect of slow sampling and potential jitter. Buildings can benefit from the application of methods and algorithms developed in other diverse fields but these methods have to be adapted to the specific issues of the buildings.

Another open challenge is to integrate the diverse array of systems in buildings into a common information-sharing framework. Although this has already started to happen with the advent of open protocols for network communication, the full potential is not yet realized. One reason for this is that buildings contain a very diverse group of systems that are made by many different manufacturers, all with their own embedded controls and electronics. The commoditization of certain building systems such as packaged cooling units has brought down costs, but these systems rarely have external communication interfaces to allow interconnectivity with other systems because of the extra costs this would incur. Although interconnection of building devices is a key to unlocking untapped energy and operational efficiencies, this cannot happen without algorithms and control methods that can take advantage of the newly available information. There is therefore a dilemma because both aspects are needed, and business will be reluctant to invest in development of just one aspect without the other being already available. Possible future avenues that could alleviate some of the barriers to connectivity are solutions such as power line networking, utilization of an existing IT backbone, and general lower-cost solutions for plug-and-play networking.

The issue of energy efficiency has again come to the fore in recent years, and this has led to new legislation and various certification programs being established in several countries around the world to encourage the design and construction of so-called green buildings. Even if financial incentives are lacking, increased concern over the environmental impacts of wasteful energy use within populations is exerting pressure on the construction industry to portray a greener and more energy-efficient image. The most visible sign of a response to these pressures is in the design and construction of modern buildings. There are several examples of new buildings around the world that make such efficient use of sunlight and wind through smart design that they can eliminate the need for mechanical heating/cooling and ventilation and almost eliminate the need for artificial lighting when sunlight is available. The manufacturers of electrical and mechanical systems are also responding to energy concerns by producing more efficient equipment that is often certified by government or other third-party organizations. However, the challenge is for the automation systems and especially the control algorithms to keep pace with the rapid evolution of buildings and inherent equipment. Failure to keep pace will result in buildings operating well below their intended efficiency levels.

62.5 Conclusions

The operation of many aspects of a building is now automated, ranging from temperature control to fire and security. The general trend is for the operation of more systems and appliances to be automated and for these to be connected to a common network. The availability of common networking infrastructure is also stimulating the demand for more advanced control and operational management methods that take into account system interactions and facilitate the optimization of building-wide criteria such as energy use. However, the adoption of IT infrastructure has in many ways outpaced the development of algorithms and automation methods that can capitalize on these advances. There is also the problem of operators not being able to cope with the abundance of data now available on BAS networks. Again, this problem is exacerbated by the lack of algorithms for processing and reducing the data into more manageable statistics or performance reports.

The complex and bespoke nature of building systems makes it difficult to develop and apply generic algorithms and, on the other hand, it is too costly to tailor algorithms to every building system. This issue is difficult to resolve but is being alleviated by standardization and commoditization of building systems. New model-free algorithmic methods for control and optimization have the potential of being able to adapt to different system types without requiring significant engineering effort or tuning. In combination, these developments may help overcome some of the barriers to the adoption of new technology for improved energy management and control in buildings.

63. Automation in Agriculture

Yael Edan, Shufeng Han, Naoshi Kondo

The complex agricultural environment combined with intensive production requires development of robust systems with short development time at low cost. The unstructured nature of the external environment increases chances of failure. Moreover, the machines are usually operated by low-tech personnel. Therefore, inherent safety and reliability is an important feature. Food safety is also an issue requiring the automated systems to be sanitized and reliable against leakage of contaminations.

This chapter reviews agricultural automation systems including field machinery, irrigation systems, greenhouse automation, animal automation systems, and automation of fruit production systems. Each section describes the different automation systems with many application examples and recent advances in the field.

Agricultural productivity has significantly increased throughout the years through intensification, mechanization, and automation. This includes automated farming equipment for field operations, animal systems, and growing systems (greenhouse climate control, irrigation systems). Introduction of automation into agriculture has lowered production costs, reduced the drudgery of manual labor, raised the quality of fresh produce, and improved environmental control. Unlike industrial applications, which deal with simple, repetitive, well-defined, and a priori known tasks, automation in agriculture requires advanced technologies to deal with the complex and highly variable environment and produce. Agricultural products are natural objects which have a high degree of variability as a result of environmental and genetic variables. The agricultural environment is complex and loosely structured with large variations between fields and even within the same field. Fundamental technologies must be developed to solve difficult problems such as continuously changing conditions, variability in products and environment (size, shape, location, soil properties, and weather), delicate products, and hostile environmental conditions (dust, dirt, and extreme temperature and humidity). Intelligent control systems are necessary for dynamic, real-time interpretation of the environment and the objects. When compared with industrial automation systems, precision requirements in agricultural automation systems may be much lower. Since the product being dealt with is of relative low cost, the cost of the automated system must be low in order for it to be economically justified. The seasonal nature of agriculture makes it difficult to achieve the high utilization found in manufacturing industries.

63.1 Field Machinery

The use of machinery in agriculture has a long history, but the most significant developments occurred during the 20th century with the introduction of tractors. As early as 1903, the first farm tractor powered by an internal combustion engine was built by Hart Parr Company. Using its assembly line techniques, Henry Ford & Son Corporation started mass production of Fordson tractors in 1917. The commercial success of tractors sparked other innovations as well. In 1924, the International Harvester Company introduced a power takeoff device that allowed power from a tractor engine to be transmitted to the attached equipment such as a mechanical reaper. Deere & Company followed in 1927 with a power lift device that raised and lowered hitched implements at the end of each row. Rubber wheels were first designed and used for tractors in 1932 to improve traction and fuel economy. Pulled and powered by tractors, an increasingly wide range of farm implements were developed in the 20th century to mechanize crop production in every step, from tillage, planting, to harvesting. Harvesting equipment trailed only tractors in importance. Early harvesters for small-grain crops were pulled by tractors and powered by tractors' power takeoff (PTO). The development of a self-propelled combine in 1938 by Massey Harris marked a significant progress in increasing productivity. The self-propelled combine incorporated several functions such as vehicle propulsion, grain gathering, and grain threshing into an all-in-one unit for better operation efficiency. The mechanization of harvesting other crops included the developments of mechanical hay balers in the 1930s and mechanical spindle cotton pickers in 1943. Tractors, combines, and other farm machinery were continuously refined during the second half of the 20th century to be more efficient, productive, and user-friendly. The success of agricultural mechanization has built a strong foundation for automation. Automation increases the productivity of agricultural machinery by increasing efficiency, reliability, and precision, and reducing the need of human intervention [63.1]. This is achieved by adding sensors and controls. The blending of sensors with mechanical actuation can be found in many agricultural operations such as automating growing conditions, vision-guided tractors, product grading systems, planters and harvesters, irrigation, and fertilizer applicators. The history of automation for agricultural machinery is almost as old as agricultural mechanization. Two ingenious examples in the early 20th century were the self-leveling system for hillside combines by Holt Co. in 1891 and the implement draft control system by Ferguson in 1925 [63.2]. Early automation systems mainly used mechanical and hydromechanical control devices. Since the 1960s, electronics development for monitoring and control has dominated machine designs, and has led to increased machinery automation and intelligence. Mechatronics technology, a blend of mechanics, electronics, and computing, is often applied to the design of modern automation systems. Automation in contemporary agricultural machines is more complicated than a single control action; for example, the modern combine harvester has automatic control of header height, travel speed, reel speed, rotor speed, concave opening, and sieve opening to optimize the entire harvest process. Farm machinery includes tractors and transport vehicles, tillage and seeding machines, fertilizer applicators and plant protection application equipment, harvesters, and equipment for post-harvest preservation and treatment of produce. Mechanization and automation examples can be found in many of these machines [63.3]. However, the wide variety of agricultural systems and their diversity throughout the world makes it difficult to generalize about the application of automation and control [63.1]. Therefore, only one type of automation – automated navigation of agricultural vehicles – will be presented here. Automated vehicle navigation systems include the operator-assisted steering system, automatic steering system, and autonomous system. These systems can relieve the vehicle operator of the repetitive and monotonous steering operation. Automatic guidance has been the most active research area in the automation history of agricultural machinery. With the introduction of the global positioning system (GPS) to agriculture in the late 1980s, automatic guidance technology has been successfully commercialized. Today, autoguidance is the fastest growing segment in the agricultural machinery industry. The following sections discuss the principles of autoguidance systems, the available technologies, and examples of specific autoguidance systems.

63.1.1 Automatic Guidance of Agricultural Vehicles

For many agricultural operations, an operator is required to perform two basic functions simultaneously: steering the vehicle and operating the equipment. The need to relieve the operator of continuously making steering adjustments has been the main reason for the development of automatic guidance systems. Excellent references to automatic vehicle guidance research in Canada, Japan, Europe, and the USA can be found in *Wilson* [63.4], *Torii* [63.5], *Keicher* and *Seufert* [63.6], and *Reid* et al. [63.7]. Figure 63.1 shows a typical autoguidance system which includes a position sensor, a steering angle sensor, and a steering actuator as the hardware components, and a path planner, a navigation controller, and a steering controller as the software components. The path planner gives the desired (or planned) vehicle position. This desired position is compared with the measured position given by the position sensor. The navigation controller calculates the desired steering control angle based on the difference in the desired and measured positions. Finally, the steering controller uses the difference in the desired and measured steering angles to calculate an implementing steering control signal and sends it to drive the steering actuator. Modern agricultural vehicles often employ electrohydraulic (E/H) steering systems. Developments in each of the system components are described in details below.

Position Sensing

The position sensing system measures vehicle position relative to a reference frame and provides inputs to the navigation controller. Most agricultural guidance applications require position measurement in two-dimensional (2-D) space. In addition, vehicle speed, heading, and rotational movements (roll, pitch, yaw) are often needed by the navigation controller.

Guidance accuracy is the primary factor in selecting a position sensor. *Auernhammer* and *Muhr* [63.8] suggested three levels of accuracy required for different farming operations: 1 m for rough operations (soil sampling, weed scouting), 10 cm for fine operations (pesticide application, soil cultivation), and 1 cm for precise operations (planting, plowing). Different position sensors are selected in a guidance system to meet the accuracy requirements for different farming operations. In general, there are three categories of positioning techniques: absolute positioning, relative positioning, and sensor fusion.

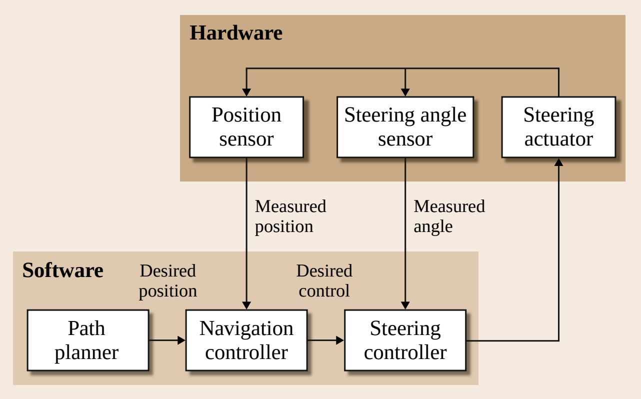

Fig. 63.1 Components of a typical autoguidance system

Absolute Positioning. The most common system of absolute positioning is the global navigation satellite system (GNSS). Currently, the NAVSTAR global positioning system (GPS) in the USA is the only fully operational GNSS. A GPS receiver calculates its position by measuring the distance between itself and three or more GPS satellites. The positioning accuracy of an autonomous, mobile GPS receiver is 5–15 m. This accuracy is generally not suitable for vehicle guidance. To improve the accuracy, a differential correction technique is applied. A differential GPS (DGPS) receiver can provide position accuracy within 2–5 m and within 1 m precision in a short time period. The DGPS receiver's accuracy can meet the requirement of positioning accuracy for most guidance applications. Further improvement in GPS accuracy requires carrier-phase enhancement (or a real-time kinematic process), typically using a local base station. The real-time kinematic GPS (RTK GPS) receiver can achieve centimeter accuracy and should meet the positioning accuracy requirements for almost all agricultural field operations. The GPS positioning technique has been successfully implemented for vehicle guidance since its inception [63.9–12]. Other absolute positioning sensors, such as laser [63.13] and geomagnetic direction sensors [63.14], have been developed and applied to vehicle guidance with varying degrees of success. However, currently the GPS receiver remains the only commercially viable choice for absolute positioning systems.

Relative Positioning. The most promising system of relative positioning is computer vision using cameras [63.4]). Vision-based sensing is mainly used for automatic guidance in row crops. Its operation resembles a human operator's steering of the vehicle – the camera is equivalent to the *eye* and the vision processor is equivalent to the *brain*. The main technical challenge to vision guidance is using image processing to find a guidance directrix, i. e., the position and orientation of the crop rows relative to the vehicle. Numerous image recognition algorithms, such as Bayes classification, edge detection, K-means clustering, and the Hough transform, have been developed since the 1980s [63.15–19]. Vision-based system can achieve excellent positioning accuracy under good crop and ambient light conditions; for example, *Billingsley* and *Schoenfisch* [63.20] reported 2 cm accuracy for their vision guidance systems. *Han* et al. [63.19] reported 1.0 cm average root-mean-square (RMS) offset error for soybean images and 2.4 cm for corn images. However, the vision-based system may not be reliable under changing lighting conditions, which are not uncommon in an agricultural environment. Other relative positioning sensors include dead reckoning, odometry, and inertial measurement units (IMU). These sensors are seldom used alone in a vehicle navigation system. Instead, they are integrated with absolute positioning sensors (e.g., GPS) in a sensor fusion approach.

Sensor Fusion. Sensor fusion is the process of combining data from multiple sensors so that the resulting information is better than when these sensors are used individually. No single positioning sensor will work for agricultural vehicle guidance under all conditions; for example, a GPS signal may be blocked by heavy tree shading. Vision sensors may not work under heavy dust conditions. Sensor fusion not only provides a way to automatically switch to a working sensor when one of the sensors quits working, but also blends the outputs from the multiple working sensors to obtain the best results. A good example of sensor fusion is integration of GPS with inertial sensors [63.21]. In this approach, GPS provides the low-frequency absolute position information, and inertial sensors provide the high-frequency relative position information. Inertial sensors can smooth out the short-term GPS errors, and the GPS can correct the bias and scale factor errors of the inertial sensors. If the GPS signals become temporarily unavailable, the inertial sensors can continue to provide position information. Sensor fusion allows the integration of several low-cost sensors to achieve good positioning accuracy [63.22]. Many algorithms are available for sensor fusion [63.23], with the Kalman filtering technique being the most common approach [63.24]. Adaptive sensor fusion algorithms have also been developed to deal with a priori unknown sensory distributions and asynchronous update of the sensors [63.25]. Terrain compensation is another example of applying sensor fusion to improve guidance accuracy on sloping terrain. A terrain compensation module measures vehicle roll, pitch, and yaw angles, and combines these measurements with the position measurement to compensate for the GPS antenna movement due to side slopes and rough terrain. Many manufactures of autosteering systems now offer terrain compensation features. Additional information on sensor fusion can also be found on Chap. 20.

Path Planning

Path planning is the generation of 2-D sequenced positions or trajectories for the automated vehicle. The sequenced positions account for the vehicle kinematics such as the minimum turn radius and other constraints. Most agricultural operations, such as tillage, planting, spraying, and harvesting, require the vehicle to travel the entire field with parallel paths at a fixed spacing equaling the implement width. Planning such paths is called coverage path planning. Coverage path planning involves two steps. Step one is to decompose a field into subregions. An optimal travel direction is found for each subregion. Step two is to find the optimal coverage pattern within each subregion. Many different algorithms have been developed for coverage path planning [63.26].

Trapezoidal decomposition is a popular technique for subdividing the field. The trapezoids are then merged into larger blocks and the selection is made using certain criteria which take into consideration the area and the route length of the block and the efficiency of driving [63.27]; *Jin* and *Tang* [63.28] used a geometric model to represent the full coverage path planning problem. The algorithm was capable of finding a globally optimal decomposition for a given field and the direction of the boustrophedon paths for each subregion. The search mechanism of the algorithm is guided by a customized cost function that unifies different cost criteria, and a divide-and-conquer strategy is adopted.

A graphical approach is often used to find the optimized coverage pattern within a subregion [63.29–31]. The processes include partitioning the area, building a partition graph, and searching the partition graph. Heuristic functions are used in the searching process to prune the search tree early so the optimized solution can be found within a reasonable time. In the case of multiple vehicles working in the same region, *Gray* [63.32] developed a path planning method.

Navigation and Steering Controllers

The navigation controller takes the desired and measured positions as inputs to compute the desired control variables, typically the lateral and heading corrections. The desired control variables and the measured variables (typically the steering angle) are fed into the steering controller to compute the steering corrections. A typical navigation control algorithm calculates the lateral and heading errors based on a reference point on the vehicle and a target (look-ahead) point on the desired vehicle trajectory. The target point may be dynamically adjusted based on speed to achieve satisfactory path tracking performance [63.33, 34].

Agricultural vehicles frequently operate in challenging conditions such as varying travel speed, operating load, and ground surface conditions. The steering controller design must be robust enough to adapt to these conditions. Several steering controllers, including proportional–integral–differential (PID) controller, feedforward PID (FPID) controller, and fuzzy-logic (FL) controllers, have been developed and implemented in the guidance system [63.35–37]. Additional information on mobility and navigation can be found on Chap. 16.

Commercialization of Autoguidance Systems

Commercial development of autoguidance systems by US manufacturers started in the 1990s soon after the availability of GPS to agricultural applications. Early GPS-based guidance systems used visual aids, commonly referred to as *lightbars*, to show a driver how to steer the vehicle along parallel passes or swaths across a field. The need to improve driving accuracy and repeatability led to the development of the next level of automation – autosteering. The autosteering system steers the vehicle within a path and the driver only needs to turn at the ends. Several preset driving patterns can be used by an autosteering system during field operations. The most popular patterns for ground applications are straight rows and curved rows. The straight-row option allows the operator to follow parallel straight paths separated by a predetermined swath width. An initial path (A–B line) is first defined by the operator and the remaining paths are generated by the guidance system. For the curved-row option, the operator drives the first curved path. The autoguidance system steers the vehicle along the consecutive paths. Other driving patterns such as circles (for center-pivot irrigation field) and spirals (for field headlands) are also available in some autoguidance systems. Autoguidance systems are now commercially available. Figure 63.2 shows an example of the GreenStar AutoTrac assisted steering system on a John Deere 8000 series tractor. Most autoguidance systems have reported a path-to-path accuracy better than 5 cm with DGPS or RTK under good field conditions.

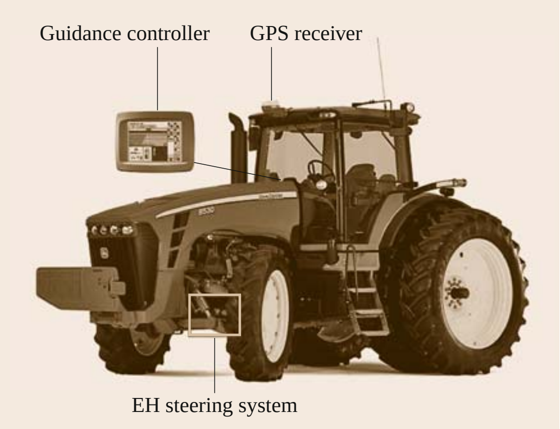

Fig. 63.2 A John Deere 8000 series tractor equipped with the GreenStar AutoTrac assisted steering system

63.1.2 Autonomous Agricultural Vehicles and Robotic Field Operations

An autonomous vehicle must be able to work without an operator. In addition to steering, it must perform other tasks that a human operator typically does: detecting and avoiding unknown objects, operating at a safe speed, and performing implement tasks while driving. Developing human intelligence for the autonomous vehicle is a challenging job.

Autonomous vehicles working in an unstructured agricultural environment must use sophisticated sensing and control systems to be able to react to any unplanned events. A typical unplanned event is the presence of a human or animal in front of the vehicle. Development of vehicle safeguarding systems is the key to the deployment of the autonomous vehicles. A number of technologies have been investigated for providing vehicle safeguarding. *Guo* et al. [63.38] used two ultrasonic sensors to detect a human being. The reliable detection range was up to 4.6 m for moving objects and 7.5 m for stationary objects under field conditions. *Wei* et al. [63.39] used a binocular stereo camera to detect a person standing in front of a vehicle. The system was able to find the person's relative motion status (speed and heading) relative to the vehicle at a distance range from 3.4 to 13.4 m. *Kise* et al. [63.40] tried a laser rangefinder to estimate the relative motion of a tractor obstacle. In general, ultrasonic sensors are low cost but their detection range is short. Stereo cameras are unreliable under changing lighting conditions. Currently, the most reliable technology is the laser rangefinder, but its use is limited to research vehicle platforms due to the high costs. Multiple levels of system redundancy must be designed into the vehicle, which often requires multiple safeguarding sensors. Development of robotic field operations is an integral part of autonomous vehicles. In order to use an autonomous vehicle, tasks must be automated as well. Over the years, agricultural equipment has evolved to accommodate the automated control of tasks [63.1]. Microprocessor-based electronics control is replacing mechanical control, and electrohydraulically powered actuators are preferred over mechanically powered ones. The adoption of CAN bus standards (SAE J1939, DIN 9684, ISO 11783) in the agricultural equipment industry has allowed networking of multiple control systems.

Task automation examples can be found in many modern agricultural machines. Examples include map-based automatic spraying of fertilizer and chemicals on sprayers, and headland management systems (HMS) for automatic sequencing of tractor functions normally associated with headland turns. *Matsuo* et al. [63.41] described a tilling robot that was able to do tillage, seedling, and soil paddling operations.

Reid [63.42] discussed a number of challenges related to the development of intelligent agricultural machinery and equipment. At present, autonomous agricultural vehicles and robotic field operations are still not reliable and durable enough to meet the requirements of the agricultural industry and its customers. Nevertheless, a number of autonomous vehicle systems have been developed as proof-of-concept machines which may lead to commercialization in the future. Some exemplary systems are briefly introduced below.

Robotic Harvester

A robotic harvester, called Demeter (Fig. 63.3), has been developed by the Carnegie Mellon University Robotics Institute for automated harvesting of windrowed crops. The robot platform was a New Holland 2550 self-propelled windrower equipped with DGPS, inertial navigation system (INS), and two color cameras. The camera system detected the cut/uncut edge of the crop, which gave a relative directrix for the harvester to follow. The camera system was also used to detect potential obstacles for vehicle safeguarding. GPS data was fused with vision data for guidance. In addition to steering, speed and header height of the harvester were also automatically controlled. In 1997, the Demeter autonomously harvested 100 acres of alfalfa in a continuous run (excluding stops for refueling). During 1998, the Demeter harvested in excess of 120 acres of crop, cutting in both sudan and alfalfa fields [63.43, 44].

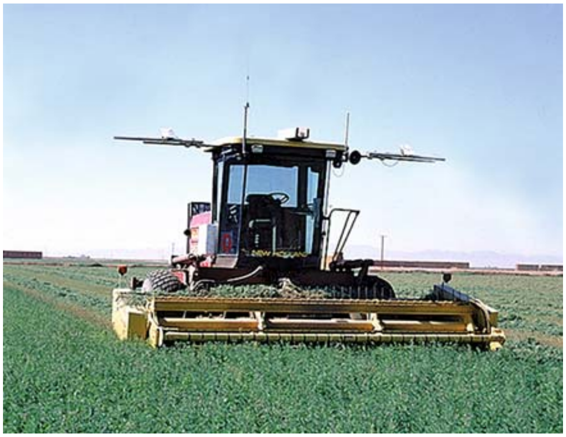

Fig. 63.3 The robotic harvester (Demeter) (courtesy of Carnegie Mellon University)

Autonomous Tractor

An autonomous tractor has been jointly developed by John Deere and Autonomous Solutions Inc. for automated spraying, mowing, and tillage in orchards (Fig. 63.4). The robot platform was a John Deere 5000 series tractor with significant modifications. The system components included the vehicle, a mobile control unit, and a base station; all were communicated

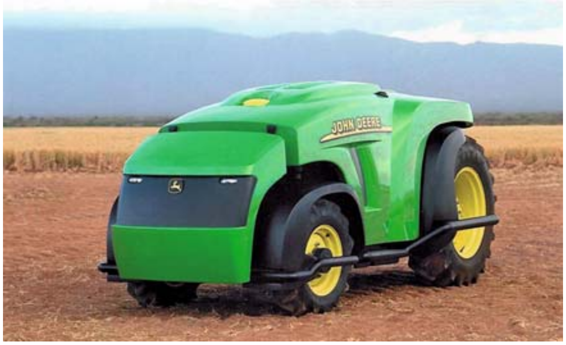

Fig. 63.4 A John Deere 5000N autonomous orchard tractor (courtesy of Deere & Company)

by a wireless CAN system. A DGPS and INS were used as positioning sensors. Vehicle controls included steering, brake, clutch, three-point hitch, PTO, and throttle. A long-range obstacle detection system was proposed for vehicle safeguarding. One of the key developments in the project was the path and mission planning, which included dynamic replanning for dynamic service events. The system design followed an industry joint architecture for unmanned ground systems (JAUGS) architecture. A proof-of-concept system was developed and successfully demonstrated, but the production decision was not made, primarily due to safety concerns.

Small Robotic Platforms

In agriculture, small robots can be used for many field tasks such as collection of soil or plant samples and detection of weed, insect or plant stress. When equipped with a larger energy source and appropriate actuators, they can also be used for localized treatments such as spot-spraying of chemicals or mechanical in-row weeding. A number of small robots have been developed, mainly at universities and research institutes [63.45]. *Astrand* and *Baerveldt* [63.46] developed an autonomous robot for mechanical weed control in outdoor environments. The robot employs a grey-level vision system to guide itself along the crop rows and a second, color-based vision system to identify the weed and to control a weeding tool that removes the weed within the row of crops. A plant nursing robot, HortiBot, was developed in Denmark as a tool carrier for precision weeding [63.47–49]. The HortiBot is a radio-controlled slope mower (Spider ILD01, Dvorák Machine Division, Czech Republic) equipped with a robotic accessory kit. A commercial stereo vision system was implemented for automatic guidance within plant rows.

63.1.3 Future Directions and Prospects

Farm productivity has increased significantly during the last century. Today, less than 3% of the US population works in agriculture, yet they produce more than adequate food for the entire nation. Agricultural mechanization has played a significant role in achieving this miracle. As next steps to mechanization, automation and robotization of farm operations can result in additional productivity improvement.

Autoguidance will continue to be the main focus of future development. The agricultural industry is now developing new systems for automation beyond autosteering of vehicles. Implement guidance and headland management are two examples. An implement guidance system automatically steers both tractor and implement and keeps the implement on the desired path. This helps overcome implement drift on hillsides or contour field conditions. The headland management system automates implement controls (e.g., to raise or lower the implement) and makes automatic turns at headland and interior field boundaries. Other guidance technologies that are close to commercialization include: sensor fusion that employs a multitude of complementary positioning sensors to improve system reliability, path or mission planning that produces the most efficient coverage paths for a single or multiple vehicles, and leader–follower systems for multiple-vehicle navigation and control, as in the case of combine harvester operation. Precision farming has become an area of enormous growth and excitement since the 1980s. The key concept in precision farming is to manage crop production at the subfield level. The labor-intensive nature of precision farming practices brings a great need for automated machines and equipment. Yield mapping and variable-rate application systems are now commercially available. In the future, autonomous field scout vehicles are needed for soil sampling, crop scouting, and real-time data collection. Small robots are desired for individual plant care such as precision weed control and selective crop harvesting. Because precision farming is considered as the future of agriculture, automation and robotics technologies will certainly become a big part of production agriculture in the 21st century.

63.2 Irrigation Systems

Irrigation is the supplemental application of water to the soil for assisting in growing crops. It is used mainly to replace missing rainfall for field crops, and to supply water to crops growing in protected environments such as greenhouses. The main objective is to supply the required amount of water to the plants at the right time. The types of irrigation techniques differ in how the water is distributed within the field. In surface irrigation systems water moves over the land by gravity and infiltrates into the soil. Surface irrigation systems include

Fig. 63.5 Sprinkler irrigation (courtesy of US Fish and Wildlife Service, USFWS/Elkins WV)

furrow, border-strip, and basin irrigation. Localized irrigation systems distribute water in piped networks by pressure, and the water is applied locally in the field and to the plant. Localized systems include spray, sprinkler, drip, and bubble systems. Automation provides efficient on-farm use of water and labor for all methods by enabling flexible frequency, rate, and duration of water supply with control of the irrigator at the right application point [63.50].

63.2.1 Types of Irrigation Systems

Flood control automation includes optimal gate operation of irrigation reservoirs [63.51]; surge flooding, which enables release of water at prearranged intervals; telemetering of paddy ponding depth and canal water level [63.52], which can be used to capture runoff and pump it back into the field for reuse; and precision con-

trol of inflow rate using ground-based remote-sensing feedback control systems [63.53]. Position of the advance of water along the furrow can be determined by contact-type sensors manually positioned in the furrow and recently by imaging systems [63.53, 54].

In sprinkler irrigation, water is piped to several locations in the field and distributed by high-pressure sprinklers or guns (Fig. 63.5). Spatially variable irrigation systems have typically used self-propelled irrigation systems – sprinklers mounted on moving platforms or center pivots [63.56, 57]. Center-pivot irrigation is a sprinkler irrigation system that is composed of several pipe segments joined together that are mounted on wheeled towers with sprinklers positioned along its length (Fig. 63.6). The system moves in a circular pattern.

Drip irrigation systems (Fig. 63.7) were invented in Israel in 1965. Water is applied slowly and directly to the soil, and only where needed. A drip irrigation system consists of valves, back-flow preventers, pressure regulators, filters, emitters, and of course the pipes (the mainline that leads water from the source to the valve, and the subpipe that goes from the valves to the connection point of the drip tubing and the drip tubes). Low-head bubbler irrigation systems are micro-irrigation systems based on gravity flow that operate at low pressure and require no filtration or pumping [63.58]. Their main advantages are simplicity, lower energy requirements, and few mechanical breakdowns [63.58]. However, their application is limited due to the complicated design and installation problems.

63.2.2 Automation in Irrigation Systems

Automation systems include irrigation time clocks – mechanical and electromechanical timers to allow accurate control of water responding to environmental changes and plant demands [63.59], with recent advances in using sensors to measure soil properties such as moisture and salinity using resistance- and capacitance-based sensors, and time-domain reflectometry [63.60, 61]. Sensors for measuring plant stress [63.62] by scanned and spotted canopy temperature measurements have been used in scheduling decisions for center-pivot and subsurface drip irrigation systems [63.63]. Sensors include infrared thermometers, thermal scanner sensors, and multispectral imaging [63.64].

High-resolution data of soil and water dynamics coupled with measurement of crop response to salinity and water stress are important for irrigation management optimization [63.65]. These data are commonly

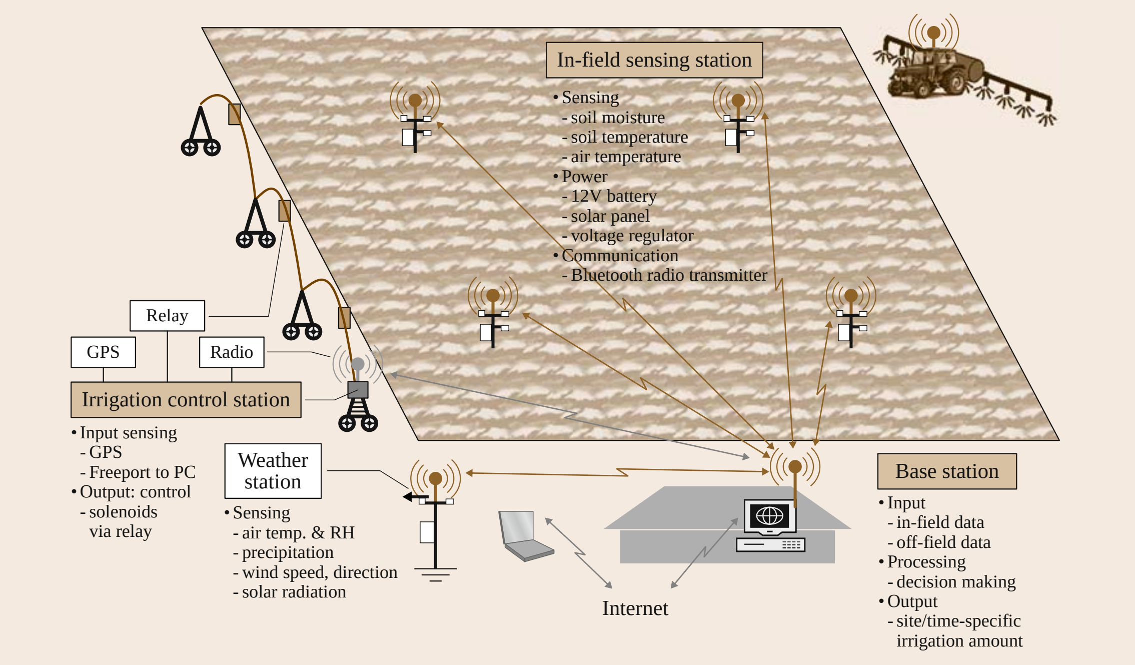

Fig. 63.8 Wireless irrigation system conceptual layout (after [63.55])

provided by weight-based soil lysimeters, with recent development of a volumetric lysimeter system [63.65].

Developments in automated irrigation systems include scheduling programs that use weather data to recommend and control time and amount of irrigation, crop growth stage and water/nutrients needs detected in real time, and commercial yield monitors and remote sensors to map crop production precisely. An example includes a real-time irrigation scheduling program for supplementary irrigation that includes a reference crop evapotranspiration model, an actual evapotranspiration model, a soil water balance model, and an irrigation forecast model, all combined using a mixed linear program [63.67, 68].

Low-cost microprocessor and infrared sensor systems for automating water infiltration measurements [63.69] are important in controlling crop yields and delivering water and agricultural chemicals to soil profile. Control of nutrients with sensors enables optimization of irrigation and fertilization management systems, useful for reducing environmental impact caused by runoff of nutrients into surfaces and groundwater by using ion-sensitive field-effect sensors [63.70].

A wireless in-field sensor-based irrigation management system was developed to provide variable-rate irrigation. Variable-rate irrigation was controlled by a computer that sends control signals to irrigation controllers via real-time wireless communications based on field information and GPS positions of sprinklers [63.55,66,71,72]. A self-propelled linear sprinkler system equipped with a DGPS and a program logic controller was remotely controlled by a base computer [63.72, 73], using a closed-loop irrigation system to determine the amount of irrigation based on distributed soil water measurements (Figs. 63.8 and 63.9). The system was operated by a program logic controller that controlled solenoids to turn sprinkler nozzles on and off. Variable-rate application was implemented by regulating pressure into a group of nozzles.

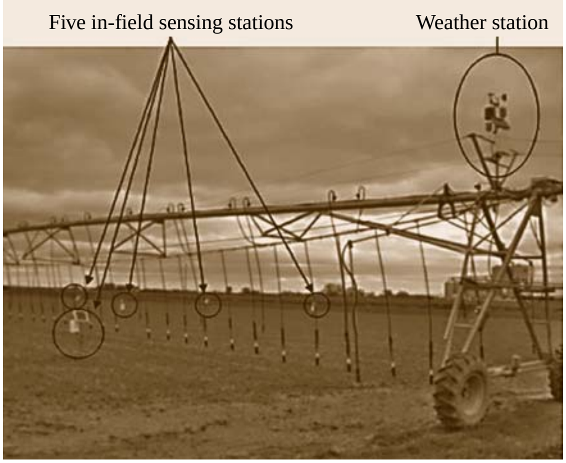

Fig. 63.9 Five in-field sensing stations and weather station mounted on the linear irrigation cart (after [63.66])

To control small areas in field irrigation, solid-set sprinkler and micro-irrigation can be controlled using centralized or distributed irrigation controls [63.74]. Architectures of distributed sensor networks for site-specific irrigation automation combining smart soil moisture sensors and sprinkler valve controllers have been developed [63.75] and are commercially available (e.g., Irriwise, Netafim). This can be expanded to closed-loop control for automated irrigation based on in-field sensing feedback of plant and soil conditions. Further developments include spot-spraying of herbicides based on real-time weed detection using optical sensors. Growers using recirculating systems often choose to sterilize the drain water before sending it back to the plants. One of the following two methods is often used: ultraviolet (UV) sterilization or ozone sterilization. Automated real-time polymerase chain reaction (PCR) system for detecting pathogens in irrigation water has been developed [63.76].

63.3 Greenhouse Automation

The greenhouse environment is a relatively easy environment for introduction of automated machinery due to its structured nature. Hence, the automated system must deal only with the variability of the agricultural product. Therefore, the development of systems is easier and simpler. Automation systems for greenhouses deal with climate control, seedling production, spraying, and harvesting as detailed in the following sections.

63.3.1 Climate Control

Greenhouses have been developed during the 20th century to keep solar radiation energy, to protect products from various hazardous natural climates and insects, and to produce suitable environments for plants by use of 100 μm plastic film or 2–3 mm glass plates. Advances in sensors and microcomputers have led to modern greenhouse operations that include control of climate, irrigation, and nutrient supply to plants to produce the best conditions for crop growth in an economical way. Environmental control enables year-round culture and shorter cultivation periods. This section outlines greenhouse environment control and automation.

Parameters and Sensors for Environmental Control

Light. Generally, there are two types of light: sunlight and artificial light from lamps. Visible light (400–700 nm, photosynthetically active radiation) is important for plant growth. Photosynthetic photon flux density (PPFD, measured in $\mu\text{mol}\,\text{m}^{-2}\,\text{s}^{-1}$) from photon sensors is appropriate when light intensity is measured for plant growth, while intensity of illumination (lux) is measured based on human sensitivity [63.77]. Although intensity and color temperature of sunlight vary from time to time and from place to place, artificial lighting devices can change them more drastically. There are several popular lighting devices: incandescent lamp, fluorescent lamp, high-intensity discharge lamp (HID lamp: Hg lamp, Na lamp, metal harido lamp), light-emitting diodes (LED), electroluminescence (EL), hybrid electrode fluorescent lamp (HEFL), and others. It is necessary to use them based on size, shape, efficiency, light intensity, life, color rendering, and color temperature of the lamp [63.78].

Temperature and Humidity. Heating and cooling in greenhouse are important for plant growth. Due to the amount of energy consumed for these operations, their control is critical. Electric heaters are used when it is necessary to specifically heat local sections such as in seedling production. Radiation in greenhouses that use sunlight can cause high air temperatures. Hence, cooling is necessary. To reduce cooling costs, curtain, infrared absorption glass (80% transmittance in visible region and 20% in infrared region), watering on glass roof, whitening the cover material, fan and pad system, fan and mist system, fog and fan system, and other methods are employed [63.79]. The thermocouple sensor is a popular measure of air temperature, while a thermo-camera and other radiation thermometers can measure radiant energy from plant parts or material bodies. Several types of humidity sensors are available: elemental devices whose electrical resistance, capacitance, or impedance is changed with humidity change. The sensors can measure 10–90% relative humidity. Humidity in greenhouses is influenced by air temperature control, transpiration from plants, water evaporation from soils, and other effects; for example, the fog and fan system can decrease temperature by 2 °C and increase humidity by 20% as compared with external air [63.80]. To reduce humidity, an electric cooling machine is sometimes used, while air ventilation is the simplest method. Thus, humidity control also requires compensation of temperature change. When greenhouse environments are controlled, both heat balance and moisture budget must be considered. PID and adaptive control methods have been developed for temperature and humidity control [63.81–83].

CO_2 Concentration. Plants absorb CO_2 and transform it into sugars and then into new plant tissue [63.84]. Every gram of CO_2 fixated by the plant yields around 10 g of new plant material. This so-called photosynthesis (or CO_2 assimilation) requires good light and suitable growing conditions.Plants consume more CO_2 under more light and also at higher CO_2 level. By CO_2 enrichment the CO_2 uptake can be increased. The effect of CO_2 on yield is proportional to the amount of time of CO_2 enrichment.

CO_2 uptake depends on the crop, the leaf area, and environmental conditions such as soil moisture and atmospheric humidity. It is expressed in gram CO_2 gas per m^2 ground area per hour ($\text{g}\,\text{m}^{-2}\,\text{h}^{-1}$). CO_2 uptake varies from 0 during very poor conditions to about $5\,\text{g}\,\text{m}^{-2}\,\text{h}^{-1}$ under excellent light conditions, and up to $7\,\text{g}\,\text{m}^{-2}\,\text{h}^{-1}$ under excellent light conditions combined with high CO_2 levels. At night no CO_2 is taken up; in contrast, plants produce CO_2 due to respiration. Hence the CO_2 level in a closed greenhouse naturally increases overnight to above-ambient levels.

Ventilation influences the CO_2 level, which has three situations:

1. CO_2 depletion: the CO_2 level is below ambient. Any leakage or ventilation will bring CO_2 into the greenhouse. Ample ventilation can prevent CO_2 depletion.
2. Elevated CO_2 levels due to CO_2 enrichment. CO_2 gas will rapidly be lost during venting, depending on the vent opening, wind speed, and CO_2 level.
3. When the CO_2 level in the greenhouse is equal to the level outside. The influx of fresh air plus the CO_2 supply exactly compensates the CO_2 absorption. In this situation there is no CO_2 loss. The CO_2 demand equals the CO_2 absorption by the plants plus the CO_2 lost by leakage or ventilation.

However, the benefits of CO_2 enrichment should outweigh the costs. This depends on the yield increase due to CO_2, as well as on the price of the produce. Moderate CO_2 enrichment is sometimes more economic than excessive enrichment. CO_2 enrichment should not go beyond 1000 ppm, as it is not beneficial for the plants and is unnecessarily expensive.Sensitive plants (e.g., young or stressed plants, sensitive species) should not be exposed to more than 700 ppm CO_2. Too high CO_2 levels cause partial closing of the pores in the leaves, which leads to low growth. Also, at higher CO_2 concentration, there is higher risk of accumulation of noxious gases that can be present in the CO_2 gas.

Air Flow. It is important to keep uniform temperature, humidity, and CO_2 in the greenhouse for proper plant culture and uniform growth. Air flow in greenhouses is achieved in different ways depending on the greenhouse structure. Natural ventilation is usually used due to its low costs. However, control of airflow with natural ventilation is limited. Therefore, it is necessary to analyze natural ventilation properly and increase ventilation efficiency. Natural ventilation is driven by pressure differences created at the vent openings both by wind and/or temperature differences. Prediction of air exchange rates and optimization of greenhouse design requires complicated models due to the coupling and nonlinearities in the energy balance models. Additional controls of air flow include on/off control of fan ventilation systems, side openings, and water sprayers [63.85] with recent developments in rate control achieved by PID or fuzzy-logic control.

Control Methods

Greenhouse climate control requires consideration of many nonlinear interrelated variables. Control models should take into account weather prediction models, crop growth models, and the greenhouse model. The following methods have been used for control: classical methods (proportional integral derivative control, cascade control), advanced control (nonlinear, predictive, adaptive [63.86]), and artificial intelligence softcomputing techniques (fuzzy control, neural networks, genetic algorithms [63.87, 88]). Control is implemented with programmable logic controllers or microcomputers. Climate controllers that use online measurements of plant temperature, and fruit growth and quality, to estimate actual transpiration and photosynthesis will be the future development. This will enable the development of closed-loop systems that use the *speaking plant* as the feedback for the control system and thereby result in effective control of the greenhouse climate [63.89, 90]. Effective control of the greenhouse climate must also incorporate long-term management plans to increase profitability and quality [63.91].

63.3.2 Seedling Production

Seedling production is one of the key technologies to grow high-quality products in fruit and vegetable production. Seedling operations such as seed selecting, seeding, irrigating, transplanting, grafting, cutting, and sticking have been mechanized or automated [63.77]. A fully automatic seedling production factory has been reported as a part of a plant factory [63.78], while a precise seeding machine which can seed in the same orientation has also been developed [63.79]. Several grafting robots and robots for transplantation from cell tray to cell tray or to pot have been commercialized. Herein, a grafting robot and a cutting sticking robot will be described as examples.

Grafting Robot

Grafting operations are conducted for better disease resistance, higher yield, and higher-quality products. Opportunities for the grafting operation are recently increasing, because of the agricultural chemical restrictions introduced to improve food safety and sustainable agriculture in the world. As the demand for grafted seedlings increases, a higher-performance model or a fully automatic model of the grafting robot is currently expected, while semiautomatic models have been commercialized since about 20 years ago. Grafting involves the formation of one seedling by uniting two different kinds of seedlings, using the side of the root of one seedling and the side of the seed leaf of the other. The side of the root of a seedling is called a stock and the side of the seed leaf, a scion. In order to graft a watermelon or a cucumber, a pumpkin is frequently used as a stock. The grafting method shown in Fig. 63.10 is called the *single cotyledon grafting method*, and is adopted as the operation process of a grafting robot for cucurbitaceous vegetables. For the stock, one seed leaf and its growing point are cut off. For the scion, the side of the root side is cut off diagonally at the middle of the hypocotyl, and the side of the seed leaf which contains the growing point is used.

Grafting operation of different kinds of plants is carried out by joining the stock and the scion using a special clip as an adhesive. Although stock seedlings and scion seedlings are hung up on spinning discs and supplied synchronously in some robot, mechanical fin-

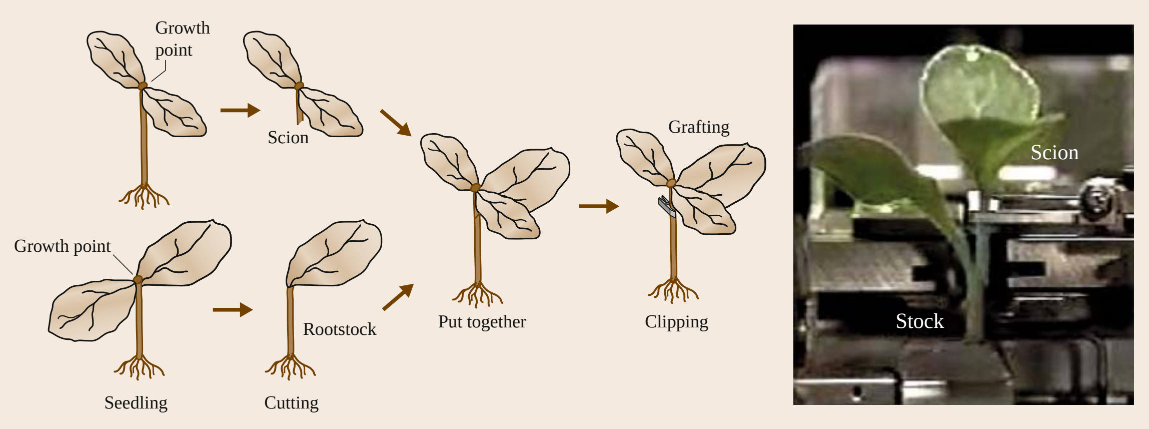

Fig. 63.10 Single cotyledon grafting method and an actual grafted seedling with mechanical fingers in the grafting operation of a robot (after [63.84, 89])

gers handle the seedlings, as shown in Fig. 63.10. Two operators hand the stock and scion to the mechanical fingers individually. At the stock cutting section, the shoot apex which contains one of the seed leaves and growing points are cut off by a spinning cutter which spins in the diagonally upward direction. On the other hand, at the scion cutting section, the side of the root is cut off at the hypocotyl by a spinning cutter which spins in the diagonally downward direction. After removing the useless part, the stock and the scion are gripped by the gripper and sent to the clipping section, where they are joined and fixed by the clip. The most important points in grafting operations are to cut the seedlings at the proper points and fix the stocks and scions precisely. To accomplish a higher success rate, the stock and scion should be properly hung for the spinning cutters when seedlings are handed into the mechanical fingers. The success rate of the grafting robot is 97% and the robot can perform grafting operations ten times faster than human workers [63.77].

Cutting Sticking Robot

Cutting sticking operations are often conducted in flower production in order to enhance productivity by using cuttings obtained from mother plants. Currently, humans manually stick the cuttings, however, the operation is monotonous and requires a lot of time and labor. A semiautomatic and a fully automatic chrysanthemum cutting sticking systems [63.80, 81] have been developed so far. In this section, a fully automatic system for chrysanthemum will be introduced, because it has a function of recognizing complicated-shaped seedlings by machine vision.

Robotic Cutting Sticking System. A prototype robotic cutting sticking system (Fig. 63.11) mainly consists of a cutting-provision system, machine vision, a leaf-removing device, and a planting device. The figure includes the latter three sections. The flow of cutting sticking operation is as follows: first, a bundle of cuttings is put into a water tank for refreshment because the cuttings are usually stored in a refrigerator for about a week until some amount of cuttings need to be prepared through picking from mother plants. The cuttings are floated on the water and spread out by adding vibrations to the tank. After refreshment in water and spread enough in a while, the cuttings are picked up by a manipulator based on information about the cut-

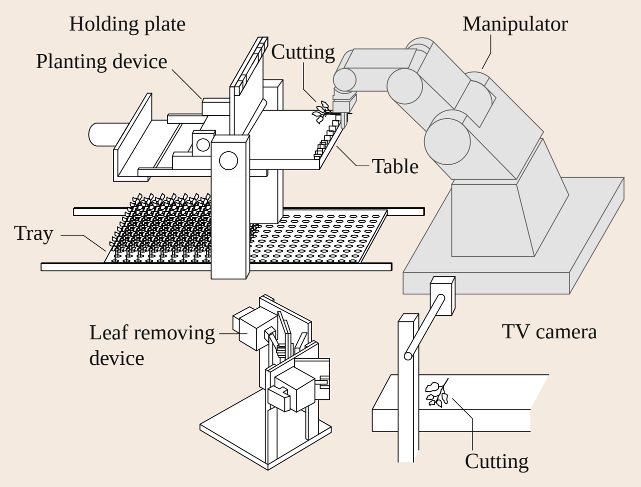

Fig. 63.11 Chrysanthemum cutting sticking system (prototype)

tings – positions and orientations from a television (TV) camera installed above the water tank.

Secondly, another TV camera (Fig. 63.11) detects the position and orientation of the cutting, which is transferred to a table from the water tank by the manipulator. The TV camera indicates the grasping position of the cutting for another manipulator, shown in Fig. 63.11. Thirdly, the manipulator brings the cutting to the planting device via the leaf-removing device. Finally, the cuttings are stuck into a plug tray by the planting device.

The leaf-removing device consists of a frame with cutters, a movable plate with rubber, and a solenoid actuator. The movable plate is driven to open and close by the solenoid actuator in order to cut lower leaves and arrange the shape of upper large leaves by chopping them with the cutters. Two identical devices are placed at an angle of 90° to cut the leaves completely since each leaf emerges at an angle of 144° from the main stem. Parts of the upper large leaves and lower petioles are cut by closing the movable plate. After this operation at the first device, the cuttings are moved to the second device and other leaves desired for removal are cut.

The planting device mainly consists of a table to place the cuttings in a row and a holding plate which opens and closes. The holding plate is driven to open and close by a motor which is mounted on the table. The table and the plate are driven in linear motion by another motor and a screw, and are rotated by a motor. A cell tray is set below the planting device. The holding plate closes after ten cuttings are placed on the table since a row of the tray has ten cells. The table rotates until it is perpendicular to the tray and moves downward. The ten cuttings are stuck into the tray together and the planting device adopts the initial position after the holding plate opens and the table moves upward.

Machine Vision. To pick up and transfer the cuttings, detection of the grasping point of the cutting is required. A monochrome TV camera whose sensitivity ranges from the visible to infrared regions was used with a 850 nm interference optical filter to enhance the contrast of the cutting on a black conveyor. The algorithm to detect the grasping point [63.82] is as follows: the complexity of the boundary line of the cutting on a binary image is investigated and candidate points of the stem tip are found. If only one candidate point is found in the image, the point is determined as a stem tip. When there are more than two candidate points, the complexity of the boundary line around the candidate points is detailed and points which are not adapted to conditions of the main stem are removed. The condition is that boundary lines around the stem tip have a lot of linearity. If only one candidate point remains after processing, the point is determined as the stem tip. In the case of plural points remaining, the whole boundary line of the cutting is detailed, the region of leaves is detected, and a candidate point which has a certain distance from the region of leaves is determined as the stem tip. When no point meets this condition or when more than two points remain even after the processing, the cutting is transferred back to the first stage, because it is too risky to determine the stem tip in these cases. The grasping point was defined as the position 10 mm above the stem tip. Experimental results indicated that about 95% cuttings are satisfactorily detected with no missed detection, and all remaining cuttings were transferred back.

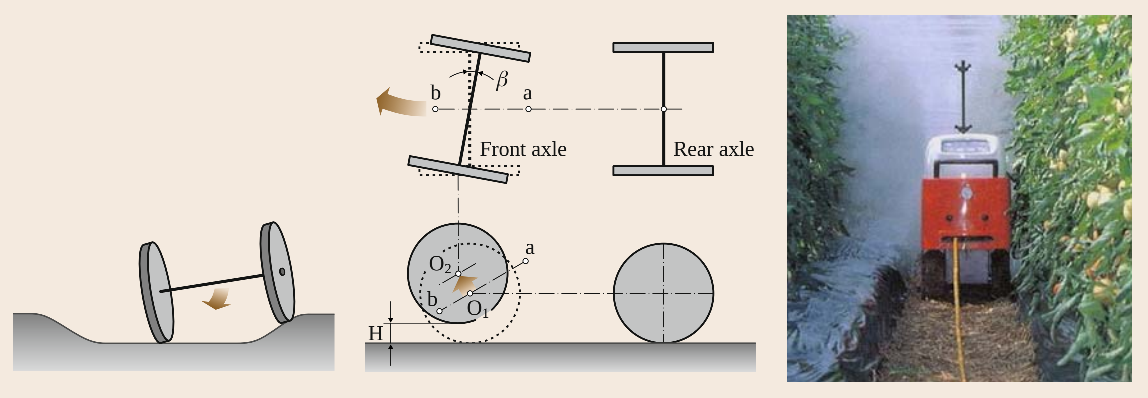

Fig. 63.12 Self-heading-correction mechanism and an unmanned sprayer (courtesy of Maruyama MFg., Co. Inc.) (after [63.84, 89])

63.3.3 Automatic Sprayers

Chemical control is required for crop production in controlled environments, and automation of the chemical spray is desirable to minimize exposure of chemicals. Spraying robots have been commercialized so far [63.83, 92, 93]. A key technology of the robots is autonomous control of the vehicle. Figure 63.12 shows the principle of the self-heading-correction mechanism. The front axle can be turned freely around an axis A–B which is fixed to the body diagonally. Assuming that a front wheel on one side runs on a ridge (it is off course), the center of this front wheel shifts from O1 to O2. At the same time, the other front wheel moves down and back. Consequently, the resulting steering angle β causes the vehicle to descend from the ridge, correcting its moving direction by itself. In the case where both a front and a rear wheel run on a ridge at the same time, the effect of the heading correction will be reduced because the steering angle β may be smaller. To obtain an appropriate steering angle, the rear tread is 35 mm shorter than the front tread. An unmanned sprayer is shown in Fig. 63.12.

Another method is called *electromagnetic induction type*. Induction wires are laid down under ridge aisles and/or headland and a vehicle with an induction sensor detecting the magnetic field created by the wires can automatically travel along the wires. When the vehicles move to the next ridge aisle in narrow headlands in greenhouses, several methods have been reported: a pivot shaft that comes out to make the turn, four-wheel steering, an additional rail system to convey the vehicle to the next aisle, and a manual method. In orchards, automatic speed sprayers using induction wires and induction pipes were developed in 1993 and 1994, respectively. A method that uses a remote-controlled helicopter has been very popular in the fields.

63.3.4 Fruit Harvesting Robots

It can be said that the history of agricultural robots started with a tomato harvesting robot [63.94]. There has been much research on fruit harvesting robots for tomato, cherry tomato, cucumber, eggplant, and strawberry [63.95–100]. Vegetable harvesting robots have also been investigated, but there is no commercial robot yet. The main reasons limiting commercialization of harvesting robots are low success rates due to diversity of plant properties, slow operational speeds, and high costs associated with the seasonal affect. However, practical use of harvesting robots is expected in the future.

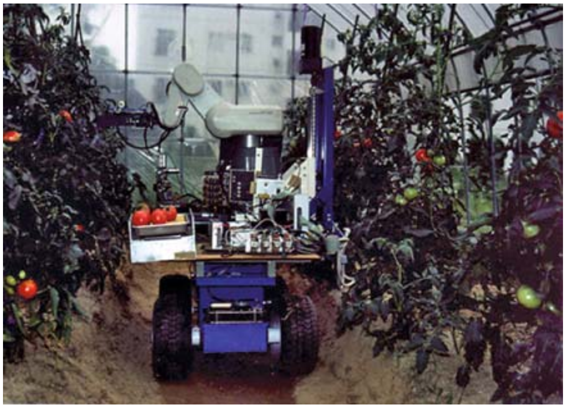

Fig. 63.13 A tomato harvesting robot

Tomato Harvesting Robot

Research on the first tomato harvesting robot started at Kyoto University in 1982 and several different types of tomato harvesting robots and their components have been developed. A cluster harvesting robot is now under development. The main components of many of the tomato harvesting robots are a manipulator, end-effector, machine vision, and traveling device, as shown in Fig. 63.13. The robot automatically travels between ridges and stops in front of a plant using photosensors and reflection plates on the ridges, which can give the location of the robot in the greenhouse. When the traveling device stops, a machine-vision system measures fruit color and location, the manipulator approaches the cluster, and an end-effector picks a fruit. After completing the operation at the location, the robot moves to the next location of the reflection plate.

Phytological Characteristics of Tomato Plant

Most tomato plants for the fresh market are usually grown on a vertical plane with supports or with hanging equipments until many fruit clusters are harvested. However, high-density single-truss tomato production systems (STTPS) have been reported [63.101]. In addition, an attempt was conducted to grow the tomato plant upside down on the tomato production system because of the smaller labor requirement for plant training and ease of mechanical operation. Some varieties are for individual harvesting while others are for cluster harvesting. Some varieties produce round-shaped fruits and longer fruits, depending on the season. There are also many fruit sizes. Fruit clusters are supposed to grow outwards due to a growth rule, but the main stem sometimes twists, which causes random cluster direction so that tomato fruits may sometimes be hidden by leaves and stems. When a robot is introduced to the production system, it should be adaptable to plant diversity.

Manipulator

The basic mechanism of a manipulator depends on the configuration of the plant, the three-dimensional (3-D) positions of its work objects, and the approach paths to the objects. In the first attempt to robotize the tomato harvesting operation, a five-degree-of-freedom (DOF) articulated manipulator was used [63.98], and a seven-DOF manipulator was investigated for harvesting six clusters [63.102]. However, the Dutch-style growing system has been popularly introduced to large-scale greenhouses throughout the world, and target fruit are always located at a similar height. Therefore, a selective compliant robot arm (SCARA)-type manipulator can be used. When the fruit cluster is transferred to a container quickly, cluster swing damping is required.

End-Effector

The fruit cluster has several fruits and their peduncles have joints in many varieties of tomato plants. When a human harvests ripe fruit one by one in the cluster, he/she can pick them off easily by bending them at the joints instead of cutting. To harvest the fruit, several end-effectors have been developed; Fig. 63.14 shows one of them [63.103]. A 10 mm-thick rubber pad is attached to each finger plate to protect the fruit from slipping and damage. The length, width, and thickness of a finger plate are 155, 45, and 10 mm, respectively. The gripping force exerted by the finger plates can be adjusted from 0 to 33.3 N, while these finger plates grip fruits ranging from 50 to 90 mm in diameter. The suction pad was attached to the end of a rack, which is driven back and forth by a DC motor and a pinion between the finger plates. The speed and stroke of the suction pad motion are 38 mm/s and 80 mm, respectively. The suction pad can be moved forward up to 43 mm from the tips of the finger plates. The moving distance and stopping position of the pad can be detected by a rotary-type potentiometer. Two limit switches are attached to both ends of the pad stroke in order to prevent the pad from overrunning.

Machine Vision

A traditional method of detecting 3-D locations of target fruits is feature-based stereo vision. A pair of identical color cameras acquire images and discriminate red-colored fruits. Based on the disparity of fruits on both images, the depth of the target fruit can be calculated. Although a small error in the 3-D location occurs because of hidden parts of the fruits, the suction pad can tolerate these error. It is not easy for stereo vision to detect all fruits locations when a corresponding problem happens due to hidden fruits and many fruits in the images. In this case, a 3-D laser sensor or area-based stereo vision may help detect the fruit depths.

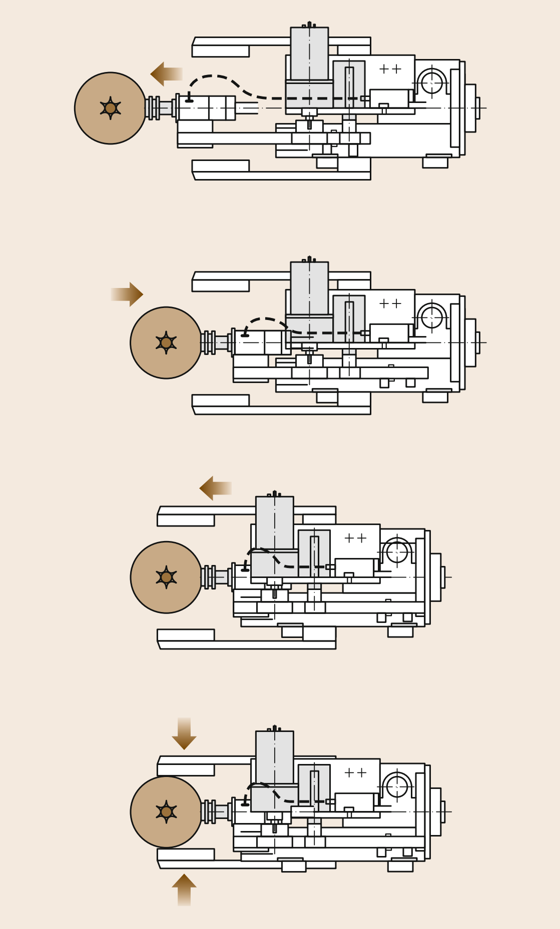

Fig. 63.14 An end-effector

Traveling Device

Figure 63.13 shows a four-wheel-type battery car on which a tomato harvesting robot is mounted. The traveling device moves and stops between the ridges and turns at the headlands to go to another ridge. In Dutch-style large-scale greenhouses, two heating pipes are usually used. It is easy to introduce a rail-type traveling device as these pipes can be used as rails. Rail-type traveling devices (manual or self-propelled) are already used for leaf picking, manual harvesting, spraying, and many other operations in greenhouses.

63.4 Animal Automation Systems

Automation of animal husbandry systems includes the development of environmental control systems, automated weighing and monitoring systems, and automated feeding systems.

Climate control of housed animals has an important influence on the productivity and health of the animals and therefore its control is very important [63.104]. However, this is a difficult and complicated task due to the nonlinear effects of the animals on the temperature and humidity conditions inside animal housing buildings [63.104]. In conditions where animals are housed outside, control is further complicated due to changing environmental conditions. Air-quality and environmental monitoring is important for environmental protection aspects and hence is gaining increasing attention and importance.

Devices for electronic animal identification and monitoring became available in the mid 1970s and have enabled implementation of advanced management schemes [63.105], specifically for livestock and swine management. The ISO standardization of injectable electronic transponders in the late 1990s expanded applications to all animal species [63.105]. Several sensors have been developed to provide individual animal parameters such as size, weight, and fat. These parameters are used for management decisions. The current new generation of sensors enable health and production status monitoring, both improving animal welfare and ensuring increased food quality and safety. Recent developments include acoustic passive integrated transponder tags using micro-electromechanical systems (MEMS) technology [63.106]. Tags may be used for tracing animals from growth to final processing for quality control and food security purposes [63.106].

The main expense in animal production systems is food intake. Automated feeding systems decrease production costs while ensuring that animals receive necessary nutrient ingredients. Group and individual feeding systems have been developed to measure and control food intake.

Production, health, and welfare controls are being introduced into modern farms using advanced information systems. Data from multiple sensors at the individual and group levels are taken on a daily basis for advanced monitoring and control. Various systems will be presented in the following sections.

63.4.1 Dairy

The dairy industry is probably the most automated agricultural production system, with almost all processes, from feeding to milking, being completely automated. In the dairy industry, many maintenance routines such as milking, feeding, weighing, and online recording of performance are fully automated on an individual animal basis. Optimal management is defined as producing maximum milk yield while minimizing costs. The computation and data-storage capacity of computers theoretically enable sophisticated decision-making to underpin the automated processes in order to obtain optimal individual and herd performance. These include automated feeders, sensors that measure daily activities of cows, and online automated parlor systems for recording milk production and quality. Reproduction monitoring includes systems for timing of insemination based on oestrus detection. Health care systems include detection of mastitis. The objective is to fully automate every process from feeding to milking to reduce production costs and maximize milk yield.

The physical process of feeding and recording actual feed consumption is based on feed administration of concentrates and roughage, ration composition, and feed calculation for an individual cow or a group of cows. Analysis of performance data indicates that cow performance under a uniform rationing regime is consistent in trend but varies in magnitude, and therefore an optimal feed policy, in terms of *efficient* rationing of concentrates, should be on an individual basis [63.107]. An alternative approach, the sweeping method, is based on average values for the herd. This can cause cows not to reach maximum milk yield because of insufficient concentrate ration or imply that excess feed be consumed since there are cows that would have reached their maximum milk yield with a smaller concentrate ration. Both result in redundant financial expense. Due to the advent of technology, the farmer is able to allocate a different amount to each cow using individual computer-controlled calf feeders [63.108] and

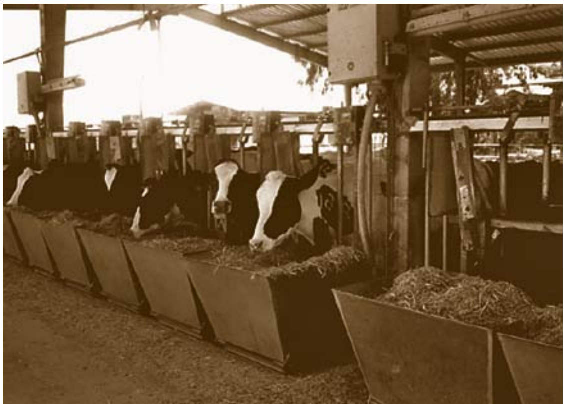

Fig. 63.15 A controlled automatic fodder consumption and feeding system (after [63.109])

integrated real-time control systems for measuring, controlling, and monitoring individual food intake of free-housed dairy cows [63.109]. Individual allocation decisions are made according to each cow's performance, Performance parameters include the individual cow's output (milk yield and composition) and measurements of physiological variables including body composition [63.110], shape, and size. An example of a system consisting of 40 feeding cells is shown in Fig. 63.15. Each cell comprises an identification system, a fodder weight system, and an automatic opening and closing yoke gate [63.109]. Each feeding stall consists of a feeding trough, an electronic weight scale and central processing unit (CPU), identification system, presence sensor, and a cylinder with valve. All components are connected to a programmable logic controller (PLC) which processes the data and activates the electropneumatic actuators. The data is backed up to a management computer. The management computer is also used as a monitoring station and a basic man–machine interface for defining basic operations and preliminary data analysis. The specific yoke design allows the cow's head to enter the yoke gate without enabling access to the fodder. This places the radiofrequency identification tag on the cow's ear close enough to the antenna and simultaneously activates the proximity sensor (by the cow's head). If the cow is allowed to eat according to the predetermined conditions, the PLC records the current scale's weight and the yoke gate bar is lowered by the associated electropneumatic cylinder. The cow may then push its head into the fodder trough and feed. The scale measures and records the weight of the fodder at predefined intervals. Each CPU scale is connected to the PLC directly via binary code to decimal (BCD) so no time delay is caused by weight transmission. A restriction bar on the fodder trough prevents the cow from pushing its head up, thereby preventing spillage of fodder. The use of presence sensors in the yoke appeared to be very important to determine if the cow had left the yoke station. The feeding troughs were arranged in a row to enable convenient dispersal of fodder (into the containers) by the passage of a semiautomated fodder dispersal wagon.

Several methods have been developed for automatic weighing of cows. Cows are weighted as they exit the milking parlor so as not to interrupt their daily regime. The motion of cows creates measurement problems, including changes along the scale due to applied forces, crowding of cows on the scales, and significant variations between cows and between the same cow at different times of the day or on different days. Dynamic weighing of cows is a common practice in many commercial farms, achieved by filtering the measured signal and averaging it or recording the peak value as the cow transfers its weight [63.111–113] using physical mathematical models that simulate cow walking [63.114].

Milking cows is a complicated task due to the physics combined (teat treatment, control of the milking unit) and variable biological components (milk secretion, udder stimulation) including the risk of infecting the udder with pathogen microbes [63.115]. Although the first proposals for mechanical milking were presented over 100 years ago, milking machinery became common only in the early 1950s, with completely automatic milking systems being introduced in the 1990s [63.116]).

First steps in automating the milking process included detection of end of milking and automatic teat cup detaching [63.115]. Various optical, capacitive, and inductive sensors were developed to detect low milk flow, which indicated end of milking [63.117]. Mechanized stimulation of udder was achieved by using pneumatic and electronic pulsators. Continuous individual variation of vacuum level, pulse rate, and pulse rate for each milking unit was developed. Milk yield recording is implemented using tipping trays and volumetric measuring systems, with many sophisticated measuring systems to separate air from milk to improve accuracy. Automatic milking requires automatic application of teat cups. Ultrasonic sensors, a charge-coupled device (CCD) camera, and a laser are used to locate the teats to control in real time the arm to adapt to the variations in teat positions, spacings, and shape and to the motions of the cow during teat attachment. In most systems a two-stage teat location process has been applied.

First, the approximate teat positions are determined by dead reckoning using body position sensors, ultrasonic proximity sensors or vision systems. The final attachment is achieved by fine-position sensors using arrays of light beams mounted on the robot arm. Automatic checks of udder condition and milk quality include online milk analysis. Milk quality is a critical parameter both from an economic point of view and from health perspectives [63.116]. Measures include conductivity, temperature, and color of milk, integrated with yield information. Biosensors have been used to measure antibiotic residues, mammary infection components, and metabolites including the development of electronic samplers that enable real-time measurements [63.118]. Online inline milk composition sensors measure in real time during milking the concentrations of fat, protein, and lactose, and indicate the presence of blood and somatic cell count (SCC) based on near-infrared analysis [63.119].

Various teat cleaning systems, including brushes and rollers or separate teat-cup-like cleaning devices, have been developed. In addition, systems for cleaning the complete system (circulation cleaning, cleaning with boiling water, cluster flushing [63.116]) are applied.

Robot milking (see Fig. 63.16 for an example), introduced in the early 1990s by several commercial companies (e.g., Lely, DeLaval, GM Zenith, Fullwood Merlin), provides increased yield by increasing the frequency of milking and improved milk quality.

Automatic health measurements during automatic milking include leg health measurement and respiration rate measurement [63.120]. Lameness detection is important due to the important welfare, health, and economic problems it causes. Leg health is also measured by measuring the dynamic weight or load of each leg while the cows are weighed on scales at the exit of the milking parlor. Several techniques have been developed including pedometers, activity meters worn around the neck, force plates that measure reaction forces on walk-through weighing systems [63.120–123], and increased respiration rate measured using laser distance sensor [63.120]. Ultrasonic back-fat sensor can provide information about the health or growth status of the livestock [63.124].

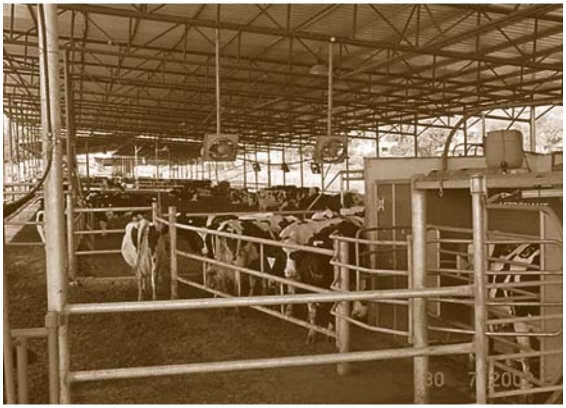

Fig. 63.16 Lely milking robot in an open barn with fans controlled when cow crowding is detected

Another important health measure is mastitis, a main reason for reduced milk yield and early losses in cows, caused by the biological activity of microbes. It can be detected by counting the number of somatic cells in milk. Various methods have been developed to measure it accurately using electrical conductivity measurements, body temperature, and milk temperature. Recently inline near-infrared sensors have been developed to measure milk conductivity and milk temperature of each seperate quarter (a sensor is connected to each udder cup) [63.119].

The primary direct parameter to detect oestrus is concentration of milk hormones (progesterone), indicating the fertility status of the cow. However, it is commonly measured only in laboratories based on samples, although biosensors have been developed for its measurement [63.125]. Several indirect parameters have been developed into automated systems, including electrical conductivity of vaginal secretion, milk temperature, and cow behavior including cow activity measurement using pedometers, heart rate, etc. Improved measurement was achieved by combining information from several parameters (e.g., combining cow activity with milk yield, feed intake, milk temperature).

Behavior measurement has been achieved using different systems: a radar-based automatic local position measurement system for tracking dairy cows in free stall barns [63.126], global positioning systems for measuring grazing behavior (*Turner* et al. [63.127], video measurements [63.128], and automatic tracking systems based on magnetic induction [63.129].

Environmental control systems in the dairy industry are less common since cows are located in barns that are open, shaded or partially shaded. Systems developed include automatic cooling using fans based on online imaging systems that detect crowding (Fig. 63.16) and microclimate and gas emissions in cold uninsulated cattle houses [63.130].

Management information systems that combine herd and individual health and production parameters [63.131, 132] are important to ensure efficient automation. Further advances in design and management of livestock environments will require development of sustainable livestock production systems accounting systematically for the environmental benefits and burdens of the processes using a lifecycle assessment process [63.133]. Strategies will need to be developed to regulate and reduce harmful gas emissions from livestock farms and land application of manure [63.134].

63.4.2 Aquaculture

Physiological rates of cultured species can be regulated by controlling the environmental conditions and system inputs. This yields increased process efficiency, reduced energy and water losses, reduced labor costs, and reduced stress and disease. Automation applications include algae and feed production, feed management, environmental controls such as filtration systems, and automated air-pressure control. An intensive water-quality monitoring program includes routine sampling (twice a week) and 24 h sampling (every 3 months) of nitrogen (NO_3, NO_2), phosphate, pH, and temperature. Fish and shellfish biomass should be sampled and seaweed should be harvested [63.135, 136].

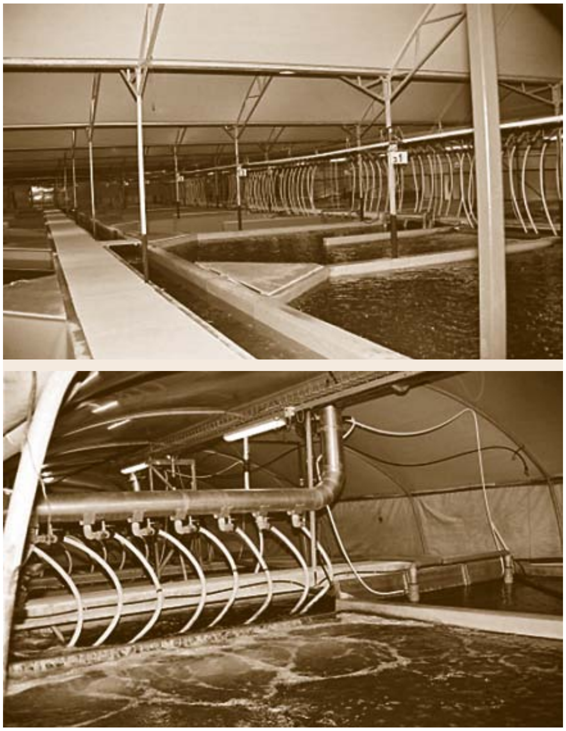

Fig. 63.17 Water channels and air distribution system. Airflow rate is controlled by regulating air-blower frequency using readings of oxygen concentration in the fish tank

Automation usually exists in closed systems such as recirculated aquaculture systems, but it can also be applied to pond and offshore aquaculture systems. Intensive recirculating aquaculture systems (RAS) reduce land and water use at the expense of increased energy requirements for operating treatment processes to support high culture densities, often with the addition of pure oxygen (see, e.g., Fig. 63.17). The use of pure oxygen is usually expensive and requires considerable energy for dissolving in the water as well as for stripping off the carbon dioxide created by respiration. In conventional RAS design gas exchange and dissolved waste treatments (e.g., CO_2 stripping and ammonia removal by nitrification) are linked into one water-treatment loop. However, because excretion rates of CO_2 are an order of magnitude greater than ammonia excretion rates this design may result in toxic CO_2 concentrations. In addition, pressurized pumping and pure oxygen addition may increase the risk of gas bubble disease. Hence, low-head recirculating system that separate the gases treatment loop (oxygen and CO_2) from the nitrification and solid filtration treatment loop by using a high-efficiency airlift producing a bubbly flow are used [63.137]. The integrated pond system (IPS) concept suggests a novel solution for environmentally friendly land-based mariculture. The IPS recycles excreted nutrients (valuable nitrogen) through algal biofilters utilizing solar radiation for their photosynthetic processes [63.138].

Accurate size and shape information of wild and cultured fish population is important for managing the growth and harvesting process including feeding regimes, grading times, and optimum harvest time [63.139]. Information on both average weight and distribution is necessary for grading, feeding, and harvesting decisions [63.140]. Machine vision has been used to determine fish size [63.139,141], mass [63.140]; color [63.141], weight, and activity patterns. The problems with image capture in ponds are the low contrast between fish, the dynamic movement of fish, and changing lighting conditions. Real-time in situ fish behavior quantification and biomass estimation has also been used for management decisions [63.142].

The cost of feed is usually the major operating cost in aquaculture [63.143]. Overfeeding results in leftovers, which leads not only to extra costs but also to poor water quality, causing additional stress and extra loads on mechanical and biofilters and oxygenation

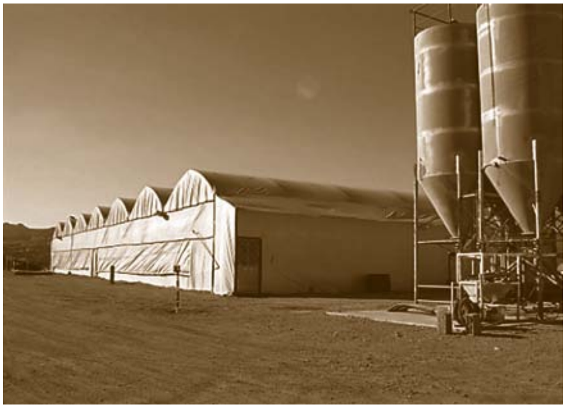

Fig. 63.18 Aquaculture closed system with a feeding station. Feed quantities are calculated on a daily basis to each fish tank according to fish weight, water temperature, and growth rate

devices [63.143]. In addition feeding rhythms affect feed conversion rates and proximal composition of fish flesh. Automated feeding systems (see, e.g., Fig. 63.18) include timer-controlled feeders [63.144], demand feeders, and automated data-acquisition systems to assess fish feeding rhythm, and acoustic, photoelectric sensors to detect the turbidity of the effluent. Hydroacoustic sensors and machine-vision systems have been used to detect left-over pellets.

Future research should be directed towards engineering environmental monitoring and controlling recirculated systems, and the development of sustainable automated systems. Considering that sustainable development is probably the major challenge faced by aquaculture [63.145, 146], one should consider sustainability, which can be considered in three main categories: environmental, economical, and sociological [63.147]. Another perspective of sustainable development relates to resource utilization and external effects that are described by various indicators (mainly in physical terms [63.136]). This should include online reporting of system failures and automation of the final harvesting and grading process [63.148], thereby improving food safety and maintaining product quality.

63.4.3 Poultry

Poultry house controllers include sensors for internal and external temperature measurement, moisture, static pressure, feed lines, water consumption, and gas and vent box status [63.149, 150]. Additional automation equipment includes feed consumption monitoring equipment, bird weight scales, feed bin load sensors, gas meters, and water meters.

Physiological signals are important for health monitoring and behavior analysis. Several systems have been developed, including an implanted radiotelemetry system for remote monitoring of heart rate and deep body temperature, and multispectral image analysis for real-time disease detection [63.151]. An automated growth and nutrition control system has been developed for broiler production using an online parameter estimation procedure to model the dynamic growth of broiler chickens as a response to feed supply [63.152]. Image based bird behavior analysis can be can be used to develop time profiles of bird activity (movement, response to ventilation, huddling, etc.) as well as to compare activity levels in different portions of the house. Time profiles of bird activity can contribute to improved feeder and water design, and enhanced distribution of ventilation air to provide more uniform bird comfort [63.149, 150, 153].

Several mechanical poultry catching systems [63.154] have led to improvements in bird welfare in addition to manual labor reduction. Systems include [63.154]: rubber paddles that rotate onto the birds from above and then push the birds onto a conveyor belt which carries them back to a loading platform where they are deposited into crates, a hydraulic drive system that advances along the poultry house and picks up the birds with soft rubber-fingered cylinders that gently lift them onto a conveyor that transfers the birds to a caging system, and the Anglia Autoflow (Norfolk, UK) batch-mode catcher that shuttles birds from collection to a separate packing unit.

63.4.4 Sheep and Swine

Robot shearing operations have been developed and commercially applied in Australia [63.155]. The sheep is constrained with straps on a movable platform. Hydraulically position clippers using force feedback control the actual shearing of the wool. Path computations are continuously updated during the shearing process.

Several feeding systems exist in sow farming: commercial electronic feeding systems that feed one at a time by enclosing each sow as it eats, electronic sow feeding systems in loose housing environments that limit the feed ration [63.156], and a computer-controlled system that allows sows to feed from one of two feed formulations to meet their nutritional requirements while satisfying their need for satiety by using bulk ingredients providing automatic body weight and average daily weight gain [63.157]. An important indicator of animal growth and health is the animals' weight, in addition to its importance in determining readiness for market. Weighing has been accomplished using walk-through weighing based on mechanical scales and imaging systems [63.158]. Physiological variables measurements include body shape and size using image analysis [63.159]. Ultrasonic probes have been applied to measure back fat for monitoring animal growth and feeding regimes. A robotic system capable of holding a sensor and placing it on the pig while it is located in the feeding stall has been developed [63.160].

Real-time behavior and control of swine thermal comfort has been achieved using imaging systems [63.161]. Planning individual showering systems for pregnant sows to prevent heat stress [63.162] as been used in automatic shower cages to prevent waste water and improve efficiency. Automatic cleaning systems to reduce infections risks between batches of pigs has been used based on an intelligent sensor for robotic cleaning [63.163].

Recent environmental policies limiting the amount of nitrogen and phosphorus that can be applied in the field have led to the development of online analysis of pig manure systems, including mobile spectroscopy instruments in the visible and near-infrared wavebands [63.164].

63.5 Fruit Production Operations

Fruit production automated systems deal with all stages of production: growing (automated sprayers, weeders), harvesting, and post harvest operation (grading, sorting).

63.5.1 Orchard Automation Systems

Fruit production operations in orchards such as pruning, thinning, harvesting, spraying, and weeding have been mechanized and automated. Even when automation systems have been developed for the same variety of fruit tree, their components differ substantially because plant training systems, cultivation methods, climate conditions, labor conditions, and other conditions and situations differ from country to country. This section describes functions, mechanisms, and important observations of automation systems in orchards.

Fruit Harvesting Robots in Orchards

Several types of shakers are working in orange fruit orchards: trunk shake and catch, mono-boom trunk shake, canopy shake and catch, continuous canopy shake, and others. These shakers are used due to labor shortage, but the harvested fruits are only for processing into juice; they cannot be consumed in the fresh market because of unavoidable damage. Several types of orange harvesting robots that have manipulators with picking end-effectors and machine-vision systems have been reported in the USA, Japan, and European countries [63.165–169]. Figure 63.19 shows an articulated manipulator with three degrees of freedom (DOFs) mounted on the base attached to the boom. It was developed by Kubota Co., Ltd., Japan. The advantage of the articulated manipulator is its compact size when folded up in a narrow space between trees. Figure 63.20 shows a prismatic arm with three DOFs driven by hydraulic power. Citrus trees have large canopies and many branches, twigs, and leaves. Since these can often be obstacles for fruit harvesting, research on robots with more degrees of freedom has also been reported [63.170, 171]. Color cameras were often used as sensing systems to detect fruit because citrus fruit have orange colors. Fruit locations are calculated by use of stereo vision, differential object size, vision servoing, ultrasonic sensors or a combination of them [63.172–179]. Their end-effectors have the function of rotating semicircular cutters so that they can cut peduncles in various directions.

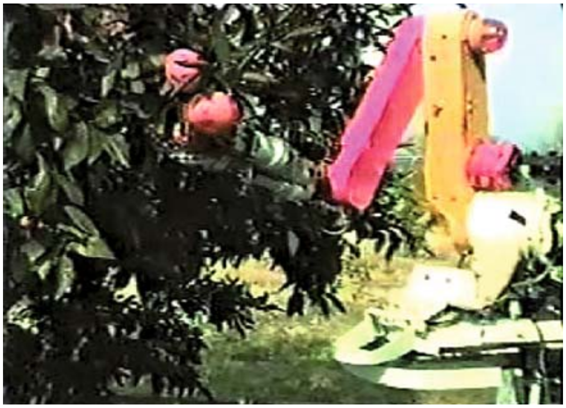

Fig. 63.19 Orange harvesting robot (Kubota Co., Ltd.)

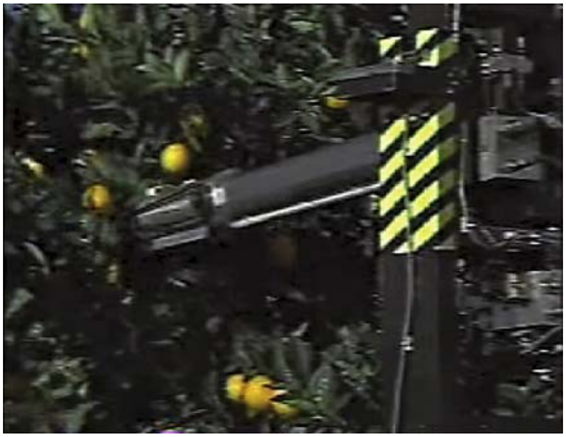

Fig. 63.20 Orange harvesting robot (University of Florida)

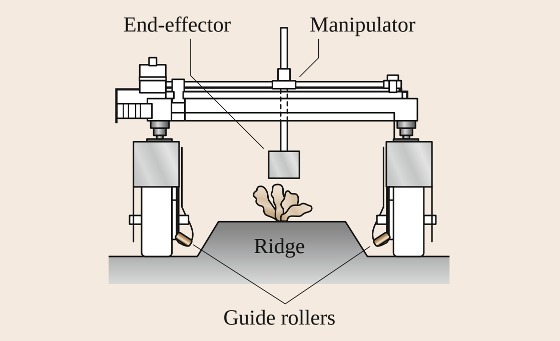

Fig. 63.21 A multioperation robot

Grape [63.180, 181], apple [63.182, 183], melon [63.184], watermelon [63.185], and other fruit harvesting robots [63.186] have also been studied. The basic mechanisms of the manipulators depend on fruit tree canopy size and shape. Grapevines in many of European and American countries are grown in crop rows, but those in Asian countries are grown on a trellis training system due to different climate conditions. Melons and watermelons are grown on the ground. There is research on fence-style training systems for orange trees [63.187] for higher-quality products. This approach of changing the training system takes a horticultural approach to accomplish a higher rate of success for harvesting robots. Since the harvesting operation is usually conducted once in a year in orchards, during a short period, a robot which can only harvest fruits is not economical. Therefore, other operations such as thinning, bagging, and spraying are needed for the orchard robot. Some of these functions are accomplished by replacing end-effectors and software [63.188].

Automation of Spraying and Weeding Operations

Control of disease, insect pests, and weeds is an essential operation to gain a stable high yield of crops and high-quality products. This operation includes biological, physical, and chemical methods. Chemical spraying is widely used in agricultural production environments. Today, technologies with high accuracy to spray only the necessary parts of the plant using a minimum amount of chemicals are required to protect workers as well as the environment.

A nozzle-positioning system for a precision sprayer was studied with a robust crop position detection system at Tohoku Experimental Station, Japan [63.189] under varying field light conditions in rice crop fields. The data from a vision sensor was transmitted to a herbicide applicator that is made up of a microcontroller, with slidable arms coupled with spray nozzles. Nozzles were driven to the optimal positions. The system was tested to evaluate its performance. It had high enough accuracy for use in Japanese rice crop fields. A fluid-handling system to allow on-demand chemical injection was developed for a machine-vision-controlled sprayer. The system was able to provide a wide range of flow rates of chemical solution [63.190].

Wiedemann et al. [63.191] developed a spray boom that could sense mesquite plants. Sprayers were attached to tractors and all-terrain vehicles. Controllers were designed to send fixed-duration voltage pulses to solenoid valves for spray release through flat-fan nozzles when mesquite canopies interrupted the light. The levels of mesquite mortality achieved were equivalent to those achieved by hand-spraying by ground crews.

The speed-sprayer (SS) has been widely used in orchards and its autonomous control is a main theme in the automation of the spraying operation. The *electromagnetic induction type* and *pipe induction type* were commercialized in 1993 and 1994 [63.192, 193]; both types require induction wires or pipes on the ground, underground, or above ground at 150–200 cm height and between tree rows. Induction sensors, safety sensors (ultrasonic sensor, touch sensors), and other internal sensors are installed in the unmanned SS, and autonomous control is conducted with fuzzy theory. Another method of SS control with genetic algorithm and fuzzy theory using GPS has been reported [63.194].

Figure 63.21 shows a multioperation robot with a three-DOF Cartesian coordinate manipulator and an end-effector [63.195]. When an end-effector shown in Fig. 63.22 is attached to the manipulator, it can weed

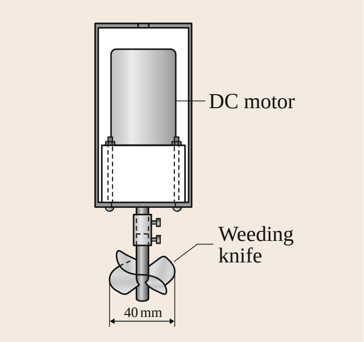

Fig. 63.22 A weeding end-effector

on the ridge between crops. Color images of the weed are fed to a computer from a color camera and the three-dimensional location of the weed is calculated using a binocular stereo method. Weed detection is conducted using color or texture difference between weed and soil or crops [63.196–198]. The end-effector was a weed knife with a spiral shape (4 cm diameter). This robot can also be a leaf-vegetable harvesting robot or a transplanting robot when the end-effectors were replaced [63.186].

63.5.2 Automation of Fruit Grading and Sorting

Because of the ever-growing need to supply high-quality food products within a short time, automated grading of agricultural products is getting special priority among many farmers associations. The impetus for these trends can be attributed to increased awareness of consumers about their health well-being and a response from producers to provide quality-guaranteed products with consistency. It is in this context that the field of automatic inspection and machine vision comes to play the important role of quality control for agricultural products [63.184–188]. Unlike most industrial products, quality inspection of agricultural products presents specific challenges because nonstandard products must be inspected according to their appearance and internal quality, which are acceptable to customers only for nondestructive methods [63.199]. Several sensors have been developed and applied for internal quality determination, including sugar content, acidity, rind puffing, rotten core, and other internal defects [63.190–194].

Fruit Grading System with Conveyors

Figure 63.23 shows an automated inspection system for quality control of various agricultural products, with fruits and vegetables being the main ones. As a representative of other agricultural products, discussion in this section is focused mainly on the orange fruit, a major agricultural product inspected by this system. The main components of the system for automated inspection and sorting can be outlined as follows:

1. Product reception from supplier
2. Container unpacking and dumping of products
3. Feeding of products to the conveyor line

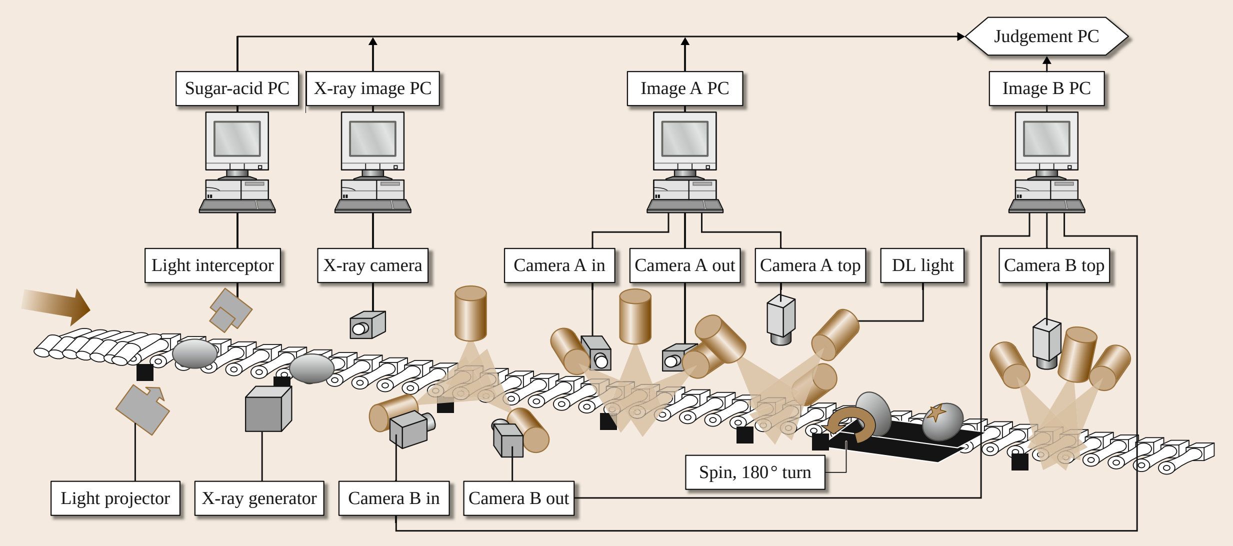

Fig. 63.23 A schematic diagram of the camera and lighting setup

4. Inspection for internal and external conditions and defects followed by assignment of quality rating
5. Weight adjustment and release of the inspected product into packing box
6. Labeling of grade and size using an inkjet printer
7. Box closure and sealing
8. Box transfer onto palette and loading ready for marketing

These features are integrated into an operational line that combines advanced designs, expert fabrications, and automatic mechanical control with the main objective of offering the best visual solutions and stable quality judgment.

Illumination and Image-Capture Devices

Illumination is one of the most important components for the machine-vision system to inspect products, because it determines the quality of images acquired, especially for glossy products whose cuticular layers are thick. Polarizing filters are sometimes used in front of lighting devices and camera lenses to eliminate halation on the acquired images [63.195]. A color CCD TV camera is often employed to sense light through photosensitive semiconductor devices, and the CCD array data is transferred by progressive scan mode to the frame storage area, representing an image of the scene [63.196]. The TV camera is equipped with one chip that transfers red–green–blue (RGB) analogue data and is set at a shutter speed of 1/1 000 s during inspection because line speed is usually 1 m/s. Image-capture boards with 8 bit level resolution and spatial resolution of about 512 × 512 pixels have been used to store and digitize video signals and output the data to computer memory for analysis or display on the monitor. Recently, a special image-acquisition device, a universal serial bus (USB) or a local-area network (LAN) is often used between TV camera and personal computer (PC) instead of the image-capture board, enabling image processing to be performed within 10–30 ms.

Product Reception and Forwarding

The first step in the inspection procedure starts at the receiving platform, situated on the ground floor. Agricultural products are packed into containers by the farmers and delivered to the inspection factory in trucks. A folk lift is used to unload the containers on one pallet and deliver them to the depalletizer device that separates the containers automatically so that they are fed one by one to the conveyor, which propels them to the upper floor, where the main inspection line is located. The depalletizer has a capacity to handle 1200–1400 pallets per hour. After depalletization, the containers are handled by the dumper machine. The dumper is an automated machine that turns and empties the containers gently and then spreads the fruit on a belt conveyor. Using specialized rollers fruits are singulated so that they are fed singly to the roller-pin conveyor before processing. To acquire a complete view of the fruit the roller pins have been designed so that the fruit is always positioned at the center point.

Internal Quality Inspection

The first stage in the inspection sequence is to determine the sugar and acid contents using a near-infrared (NIR) inspection system. A special sensor determines the sugar content (brix equivalent) and acidity level of the fruits from light wavelengths received by specific sensors after light is transmitted through the fruit. The sensor photoelectrically converts the light into signals and sends them to the computer unit, where they are processed and classified. In addition, the internal fruit-quality sensor measures the granulation level of the fruit, which indicates its internal water content. Next, the fruit is conveyed to the x-ray imaging component, which inspects for biological defects such as rind puffing and the granulation status of the juice sacs. X-ray imaging operates by transmitting x-rays released from a generator through the orange fruit. The emitted optical x-ray image is relayed to the x-ray scintillator, an optical device that consists of a thin coat of luminescent materials through which x-rays are converted into the visible light of a normal image. The resulting image is captured by a monochrome CCD camera and copied to computer memory through an image-capture board.

Image Analysis

At the next operation, the fruit is conveyed to the third inspection stage where the main image processing and grading takes place using factory automation computers (Fig. 63.23). Six CCD cameras set in random trigger mode acquire images of the fruits as they are conveyed at constant speed. Firstly, two side cameras on the right side, placed equidistance from the central position of the fruit, capture images of the right side of the fruit. Next, two side cameras on the left side, again placed equidistance from the central position of the fruit, capture images of the left side of the fruit. Next, a top camera acquires the top surface image. Finally, the fruit is then spun through 180° around a horizontal axis by mechanically controlled roller pins, which facilitates the acquisition of another image of the lower surface by a sixth camera. Images are captured by CCD cameras after a trigger signal is received through the digital input/output (DIO) board. Sensors, wired to a sequencer box, are used to track the fruit position and the output is relayed to the DIO board from where the program reads the 8 bit output data.

Image processing is then executed and the following features are inspected:

1. Size (maximum and minimum diameter, area, and extrapolated diameter)
2. Color (color space based on hue, saturation, intensity (HSI) values and RGB ratios)
3. Shape (perimeter L, L^2/area, inflection point of outer surface, and center of gravity)
4. Bruise (based on intensity of blue color level and summation of color levels for blue, and R–G derived images)

Results of processing are written to a shared memory area using a memo-link from where a judgment PC makes decision about the quality of the fruit. Grading for quality is assigned by ranks of between four and six. Graded fruits are conveyed to the weight adjustment machine, which controls the total weight of oranges to be packed in a box according to preset values. Between four and eight weight rankings of fruits are used to fill different pack boxes. An automatic barcode labeler then prints the grade and size outputs on the box using an inkjet printer before the packing box is closed by the packing machine and then automatically sealed by the case-sealer machine. At the end of the product inspection line a robot-controlled palletizer completes the process by arranging the boxes onto palettes ready for onward loading onto trucks and transport to consumer markets.

Data Maintenance

An important feature of the grading system design is that it is adaptable to the inspection of different products such as potato, tomato, persimmon, sweet pepper, waxed apple, and kiwi fruits with adjustments only to the processing codes. Several lines for orange fruit inspection combined with high conveyance and high-speed microprocessors enable the system to handle large batches of fruit product at high speeds. Apart from quality inspection another objective of this system is to gather data about product performance. Identification of certain defects and counts can lead to the discovery of the cause and its severity. All data from receipt of fruits at the collection site through the analytical processes, packing, and shipping is stored in an office computer connected through a local-area network (LAN) to the corresponding factory automation PCs. Experienced personnel manage the data, based on which day-to-day operations can be monitored remotely. By making product performance records available on the Internet it will be possible to monitor performance online and provide a useful service to the customers. All in all, the customer of a product is the final judge of its quality. Therefore, keeping internal standards and specifications in line with customer expectations is a priority that is achieved through good relationships and regular communications with the customer.

Fruit Grading Robot

Based on the technologies of the grading system described in the previous section and robotic technologies, a fruit grading robot as shown in Fig. 63.24 was developed in 2002. This robot system has two three-DOF Cartesian manipulators, 16 suction cups as end-effectors, and 16 machine-vision systems consisting of 16 color TV cameras and 36 lighting devices. This can be applied to tomato, peach, pear, apple, and other fruits.

Operation flow with this grading system is as follows:

1. When products are received, four blocks of containers (a block consists of ten containers) are loaded on a pallet.
2. A block of the containers is lifted up to the second floor, where the main parts of the grading system work, and a container separator sends containers one by one to a barcode reader.

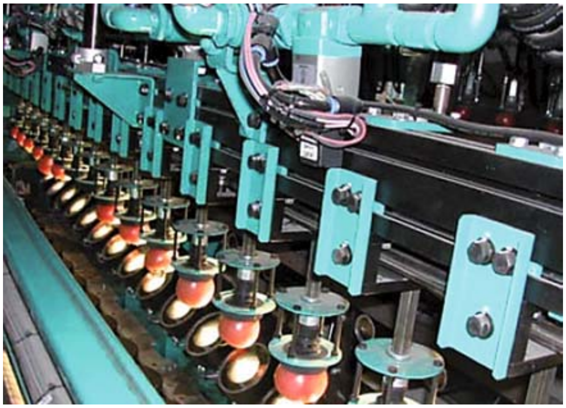

Fig. 63.24 A tomato fruit grading robot

3. After obtaining information from each barcode attached to a container, the container is sent to a robot, the fruit providing robot.
4. The robot sucks fruits up by using suction pads and moves them to a halfway stage.
5. Another robot, the grading robot, picks fruits up again from the halfway stage and bottom and side images of fruits are acquired by TV cameras during transferring fruits.
6. The robot transfers them to trays on a conveyor line and a top image of the fruit is acquired in a camera box.
7. After appearance inspection, internal conditions and sugar content are inspected by an infrared analysis sensor.
8. Fruit that pass the internal quality sensor box are packed into a corrugated cardboard box by a packing robot based on their grading results. Grade, size, and name of fruit variety are printed on the box surface by an inkjet printer and the box is closed and sealed.
9. Finally, the boxes are transferred onto palettes and are loaded into a truck for marketing.

Figure 63.25 shows the actions of the two manipulators: the fruit providing and grading robots. A container in which 8 × 6, 6 × 5, 6 × 4 or 5 × 3 fruits are filled is pushed into the working area of the providing robot by a pusher (1). The providing robot has a three-DOF Cartesian coordinate manipulator and eight suction pads as end-effectors. The robot sucks eight (maximum) fruits up (2) and transfers them to a halfway stage, spacing fruit intervals in the *y* direction (3). Two providing robots independently work and set 16 (maximum) fruits on a halfway stage. A grading robot which consists of another three-DOF manipulator (two prismatic joints and a rotational joint) and 16 suction pads sucks them up again (4) and moves them to trays on a conveyor line. Bottom images of fruits are acquired as the grading robot moves over 16 color TV cameras. The cameras and lighting devices turn down 90° following the grading robot's motion (5). Before releasing the fruits to trays on the line, the TV cameras acquire four side images of fruits as they rotate through 270° (6). After image acquisition, the robot releases the fruits into trays (7) and a pusher pushes 16 trays to a conveyor line (8).

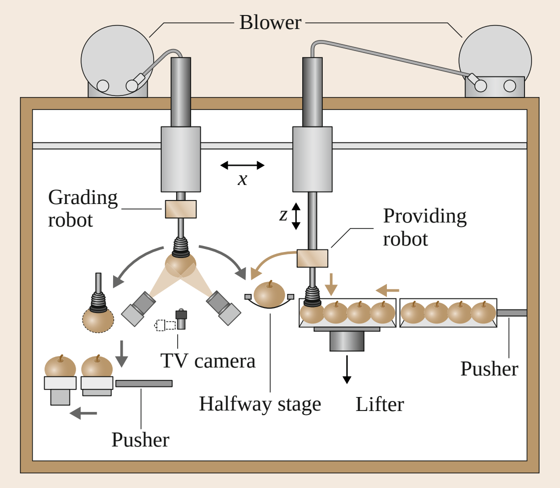

Fig. 63.25 Actions of robots

This grading robot's maximum speed was 1 m/s and its stroke was about 1.2 m. It took 2.7 s for the robot to transfer the 16 fruit to trays, 0.4 s to move down from the initial position, 1 s to move back from releasing fruits, and 0.15 s for waiting. Total time was 4.25 s to move back and forth for the stroke. This makes this robot performance approximately 10 000 fruit/h. In this system, four blowers with specification of 1.4 kW, 3400 rpm, 38 kPa, 1.3 m^3/min displacement were used for two providing robots and a grading robot. About 30 kPa vacuum force was suitable for sucking peach fruit, while 45 kPa was used for pear and apple fruits and no damage was observed even after sucking peach fruits twice. The tray has a data carrier (256 byte EE-PROM), and grading information of each fruit is sent from a computer to the data carrier through an antenna after image processing. A conveyor line transfers the trays at 30 m/min [63.197].

63.6 Summary

Despite the problems in introducing automation into agricultural production systems many automation systems have been developed and are commonly applied in agricultural operations. Automation has increased the efficiency and quality of agricultural production systems.

However, automated or semiautomated farming is far from a reality in many parts of the world. Due to cheap labor in third-world countries, much of the work on farms is still performed manually. Despite the large capital investment needed to purchase the equipment, automation will probably be introduced also into these countries to provide the needs for increased production and land efficiency.

In industrialized countries the production trend is towards large-scale farms and hence automation will be advanced and commercialized to make this feasible. Farmers must produce their food at competitive prices to stay in business and automation of farming technology is the only way forward. With the improvement of sensors and computers, and decrease of automation equipment costs, this is becoming feasible and more systems will be introduced. The current century will probably see significant advances in automation and robotization of farm operations. The future farm will include integration of advanced sensors, controls, and intelligent software to provide viable solutions to the complex agricultural environment.

64. Control System for Automated Feed Plant

Nick A. Ivanescu

Many factories, especially in developing countries, still use old technology and control systems. Some of them are forced to replace at least the control and supervising system in order to increase their productivity. This chapter presents a modern solution for updating the control system of a fodder-producing factory without replacing the field devices or the infrastructure. The automation system was chosen in order to allow correct control of the whole plant, using a single programmable logic controller (PLC). Structure and design of the software project is described. Also, several interesting software solutions for managing special processes such as material extraction and weighing machines calibration are presented. Production quality results and future development are also discussed. In the last part of the chapter some guidelines for automation of a chicken-growing plant are presented.

64.1 Objectives

One of the recent projects we worked on for was to design and execute a complete control system for a combined fodder-producing plant. From the start it must be specified that we had to find solutions to command and control the existing machines, and the only things that could be replaced or added were sensors and transducers. Most other devices, such as motors, limit sensors, tension transducers, etc., remained in place. Also 90% of the cable system was retained.

This project had several objectives:

1. Design of the command and control system, taking into account the electrical characteristics of the machines, and the number and type of the electrical signals coming from and going to the system
2. Development of a powerful software system to allow manual control of the whole plant, continuous visualization of all signals and commands, and full automatic control of the production process
3. Real-time communication with personal computers in a local network, enabling managers and other personnel to supervise the production flow and results
4. Ensuring that the total quantity of the final product should not exceed or be less than 5% of the programmed quantity. Also the percentage of every component of the resulted material should be less than 5% different from the calculated recipe.

64.2 Problem Description

A combined fodder plant produces food for industrial grown poultry. This food is a mixture of different types of cereals combined with some concentrated products.

Practically, there are three main areas inside the factory:

- The raw material storage area, consisting of several storage bins
- The weighing and mixing area, where the final product is obtained
- The finished-product storage area, consisting of several storage bins, where the resulting product is stored while waiting to be taken to poultry farms.

Part of the plant is presented in Fig. 64.1.

Let us take a brief look at the components of the plant shown in Fig. 64.1:

- There are eight raw-materials storage bins, containing eight different types of cereals.
- From these bins material can be extracted to weighing machine 1, by means of several extractors.
- Weighing machine 1 is used to weigh specific quantities of cereals, with a maximum of 2000 kg supported by the machine. The machine supplies an analog signal in voltage, which we converted to a unified 4–20 mA signal.
- The intermediate tank between weighing machine 1 and the mill is needed because the speed of the mill is lower than the evacuation speed from weighing machine 1.
- The mill is used for milling the cereals.
- The grinding machine is used for grinding the milled cereals.
- The mixing machine is a large tank where the processed cereals are mixed together with some special oil and another component (premix).
- The materials circulate between the machines by means of several transporters and elevators.
- Weighing machines 2 and 3 weigh, respectively, oil and premix extracted from the milling machines. Details will be given later in the chapter.

The production flow can be briefly described as follows:

1. The human operator must establish the quantities for every type of cereal, for oil, and for premix that must be part of the final product. Quantities are determined for only one charge of extraction, because the capacity of the weighing machines is limited. Also the number of charges is specified, in order to produce the whole amount of material wanted.

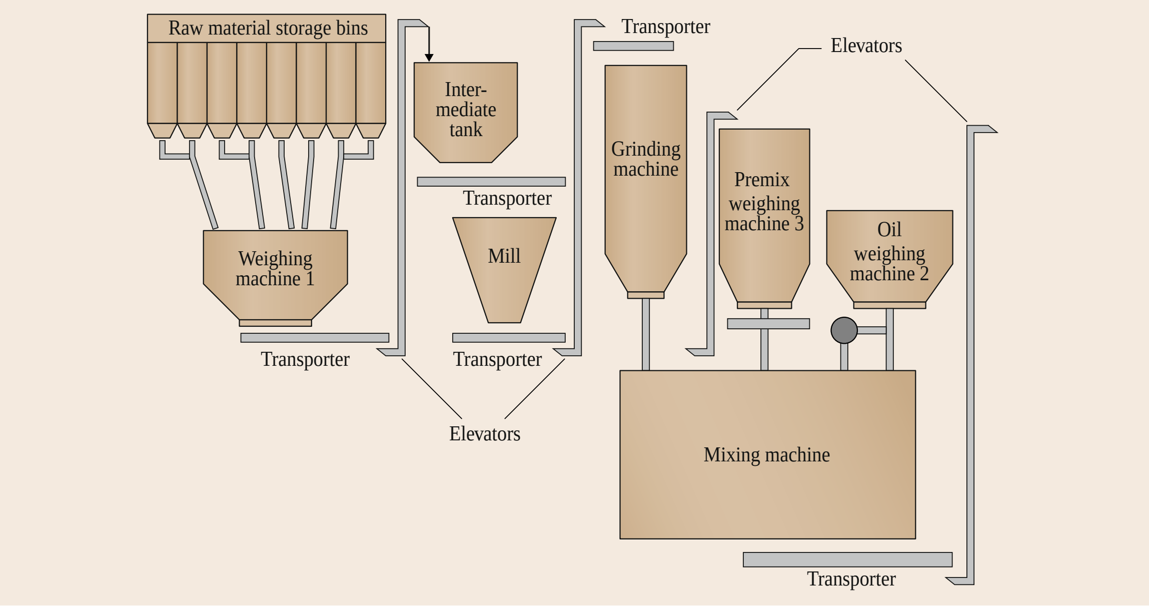

Fig. 64.1 Production part of the plant

2. The process starts with extraction of specified quantities of cereals into weighing machine 1.
3. Weighing machine 1 is emptied into the intermediate tank, if some specific conditions are fulfilled. Immediately a new extraction should begin for the next charge.
4. The milling and grinding processes are done automatically; some sensors signal when the corresponding tanks are empty.
5. When the grinding is over, material must be transferred to the mixing machine. After a short time, oil and premix are also loaded into the mixing machine.
6. The mixing process lasts several minutes (a configurable period of time), at the end of which the machine is opened and the finished product is transported to the finished-product storage bins and the charge can be considered ended.

It is necessary to say that, in order to obtain high productivity, another charge must be in course of processing, even if the previous one is not finished. Of course the detailed process implies several constraints and internal conditions, some of which will be discussed later in the chapter.

64.3 Special Issues To Be Solved

One of the first and most difficult parts of the project was to identify all analog and digital signals that must come from and go to the installations. Without proper documentation or an electrical schematic of the plant, this job proved to be extremely time consuming. After analysis, 192 digital inputs, 126 digital outputs, and 12 analog signals were identified, together with the cables connected to them from the previous control system.

Another issue that had to be taken into account was the improper grounding of most of the machines inside the plant, which can cause undesired variation of analog signals. Most of the work regarding this issue was done in software because electrical solutions were not feasible (as they should have been taken into consideration during the design and build of the factory).

During study of the rest of the machines in the plant, some special situations were determined regarding weighing machine 3. Firstly, the four tensions transducers that measured the weight inside the machine were not of the same type. One transducer had been replaced in the past but with a different type, and had a different output electrical tension for the same measured weight compared with the other three transducers. This resulted in nonlinear variation of the unified analog signal with the weight inside the machine. The solution to this problem is described later in the chapter.

The other special effect discovered was that, when weighing machine 3 was opened and premix was transferred to the mixing machine, an air flow developed and pushed up the weighing machine, resulting in incorrect measurement of weight during this process. Stabilization of the signal appears many seconds after extraction stopped. A software solution was chosen for this practical problem also.

64.4 Choosing the Control System

To choose the main control device for such an industrial system correctly, several factors must be taken into consideration, including:

- The number and type of input/output signals
- The complexity of the software that must be developed
- The communication facilities that are requested and can be fulfilled
- The ease of developing a human–machine interface for supervising and commanding the processes
- The budget allocated to this part of the control system.

The solution chosen in this case was the ThinkIO PLC from the German company Kontron. The ThinkIO device is an innovative concept to integrate high-performance personal computer (PC) functionality, fieldbuses, and input/output (I/O) modules. It has a powerful Pentium processor, two Ethernet interfaces, universal serial bus (USB) for keyboard and mouse, and digital visual interface (DVI) for liquid-crystal display

(LCD) or cathode-ray tube (CRT) displays. For automation applications it can run programs developed in 3S Software Codesys package. Also it can handle hundreds of I/O signals, so it fulfilled the system necessities. Another big advantage of this device is that even the human–machine interface runs on it, so practically you do not need a separate PC to supervise the process or to send manual commands to it. We chose the Linux operating system for this PLC. An object linking and embedding (OLE) process control (OPC) server runs on this PLC so communication with it is easy and reliable. After completing connection of it to the field devices, the next step was to design and develop the software. However, before designing the software solution, there was an important job to do, essential for correct results of the production process.

64.5 Calibrating the Weighing Machines

All three weighing machines have some tension sensors that output an electric signal that is (theoretically) proportional to the weight in the machine. Weighing machines 1 and 3 have four sensors, mounted at the four corners of the weighing tank, that output a voltage (0–100 mV) proportional to the force on each sensor. The sum of the four tensions is converted to a current in the range of 0–20 mA and connected to an analogue input of the PLC.

A potential problem could appear if the sensors are not of the same type (different output tension range) or are not mounted perfectly symmetrical. As already described, such a situation occurs for weighing machine 3. The output of one of the sensors had a different tension range to those of the other three sensors.

The standardization procedure implies the determination of the relation between the weight of the weighing machines and the output current of the measurement sensors, practically being the relation between the weight and the engineering units resulting from the analog-to-digital conversion inside the PLC.

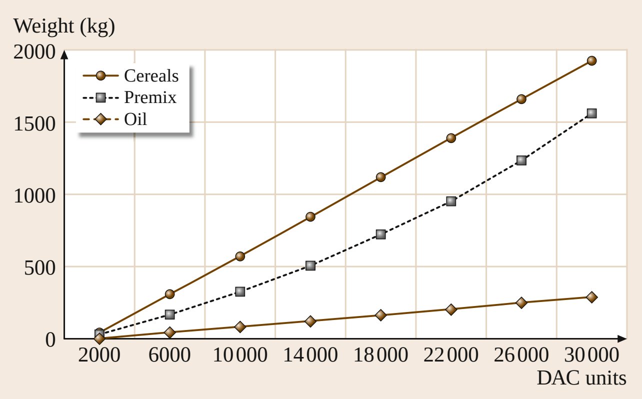

Fig. 64.2 Characteristic of the three weighing machines, for cereals, premix, and oil

To determine this relation, we used 100 standard 20 kg units. Weighing machines 1 and 3 can support up to 2000 kg load. To determine the specified relation, we loaded the machines with consecutive 200 kg weights, until 2000 kg was reached. After that, the weights were removed, 200 kg at a time, until there was no load on the machine. Fortunately, the hysteresis phenomenon was very small and practically did not matter. The characteristic of the machines is shown in Fig. 64.2.

Machine 1 proved to be linear so we adopted (64.1) for calculating the instantaneous weight value

$$\text{weight1} := (\text{adc\_value} - \text{init\_value1})/\text{scale\_1}\ , \tag{64.1}$$

where:

- weight1 is the instant value of the weight (in kg).
- adc_value is the numerical value obtained by converting the analogue signal (0–20 mA) to 12 bits.
- init_value1 is the numerical value obtained from sensors when machine 1 is empty (because the weighing machines have their own weight).
- scale_1 is the approximated slope of the line, calculated using the arithmetic average of all DAC units/kg ratios at all the measured points (Fig. 64.2).

Machine 3 had a different behavior because one of the sensors is of a different type to the other three, outputting a tension in a smaller range than the others. The result is that the resulting graph is more of parabolic type. Anyway because determination of the parabolic equation is very difficult, we chose to piecewise-linearize the graph on ten portions. So the formula for one portion reads

$$\text{weight3} := (\text{adc\_value} - \text{init\_value3})/\text{scale\_3}i\ , \tag{64.2}$$

where:

- weight3 is the instantaneous value of the weight (in kg).
- adc_value is the numerical value obtained by converting the analogue signal (0–20 mA) on 12 bits.
- init_value3 is the numerical value obtained from sensors when machine 1 is empty (because the weighing machines have their own weight).
- scale_3i is the approximated slope of the approximation line on portion i, calculated from the values of start point and end point of the corresponding portion (Fig. 64.2).

Weighing machine 2 has only one tension sensor so the relation between the weight value and the output tension is linear, so the same formula was used for the whole weighing range (0–120 kg)

$$\text{weight\_oil} := (\text{can\_value} - \text{init\_oil})/\text{scale\_oil}\ , \quad (64.3)$$

where the elements of (64.3) have the same meaning as in previous equations.

64.6 Management of the Extraction Process

Another delicate process that had to be correctly controlled is the cereals extraction and premix unloading. The cereals are transported from the storage bins with a system of conveyors and elevators and are loaded into weighing machine 1 using several extractors. However, because the end of the extractors is some distance above the weighing machine, there is still some material in the air that will fall into the weighing machine even after the extractor's motor is stopped.

The quantity falling down in the machine after stopping the extractor depends on various factors:

- Type of cereal
- Quantity desired to be extracted
- Distance from the end of extractor to the weighing machine.

The same considerations apply for unloading the premix in the mixing machine, but the quantity falling after the unloading lid is closed is small. The solution adopted in order to minimize extraction errors was to use some estimated *in-air* quantity to anticipate the quantity loaded into the machine after the extractor is stopped. In this case the extractor should be stopped before the weighing machine measures the desired quantity. So the estimation (for one material) has an initial value but is adjusted at every extraction with the simple formula

$$\begin{aligned}\text{new\_estimation} &= \text{old\_estimation}\\ &+ 0.5(\text{last\_extracted\_quantity} - \text{wanted\_quantity})\ ,\end{aligned} \quad (64.4)$$

where:

- new_estimation is the (*in-air*) estimated quantity that will be used to determine the moment when the extractor must be stopped for the current extraction.
- old_estimation is the estimation used for the previous extraction.
- last_extracted_quantity is the concrete quantity previously extracted.
- wanted_quantity is the ideal quantity that should be extracted.

In this way in three or four extractions the error practically drops below 1 kg. Taking into account that a complete production cycle has tens of extractions, the total extraction error is very small, less than 5%.

After weighing machine 1 is loaded with all types of cereals needed for the current charge, the machine is unloaded completely, when several conditions are fulfilled. Premix and oil quantities are measured somehow differently, i.e., when they are unloaded from the weighing machines into the mixing machine, but the procedure is similar.

64.7 Software Design: Theory and Application

The Codesys logical software package was used to develop the control programs. The software project should have had different functions:

- Graphical user interfaces, for configuring the process, for monitoring all the production stages and

all the factory areas, and for manual command of the installations in the factory
- Automatic accomplishment of planned production
- Implementation of constraints and conditions between different machines
- Sorting and mediation of analogue signals
- Network communication with PCs.

First let us briefly discuss some *theoretical* approaches regarding the conception of an automation software project. The easiest and most natural type of programming language that should be used for the control part of a program is the sequential function chart. This programming language is supported by the large majority of PLCs producers. Even if this language is not implemented in a PLC and other languages, such as ladder diagrams, must be used, there are algorithms that help the programmer to *convert* a logical diagram in a ladder diagram. On the other hand, other types of jobs, such as implementation of synchronization and conditioning of events can be done more easily in a ladder diagram type of program. Some examples are shown later in the chapter.

When several industrial processes are be controlled by a single PLC, the best idea is to control every execution device (such as motors, actuators, valves, and so on) *separately* in a separate logical diagram. If related events for several devices are somehow connected, it is better to develop a single logical diagram for their control. Relationship or synchronization between logical diagrams is achieved by *global variables*.

64.7.1 Project Structure and Important Issues

The structure of the software project is shown in Fig. 64.3.

The idea was to separately control almost every subprocess that takes place during the production flow (extractions, mixing, unloading and so on) [64.1]. Most of the programs are written in sequential function chart (SFC) programming language, the *interblocking* program is written in the ladder diagram (LD) language and other smaller programs are written in structure text (ST) language. All of these programs run *simultaneously* in the PLC memory.

Briefly described, the programs have the following functions:

- *Extraction* programs take care of the extraction of each type of cereal, with one program for each type of cereal (written in SFC).

  Premix_unload(PRG)
  Sort(FUN)
  Time_read(FUN)
  Time_Reader(PRG)
  Weigh1_unload(PRG)
```

Fig. 64.3 Structure of the software project

- The *interblocking* program takes care of all conditioning between different installations together with automatically stopping some motors when they reach their limits (Fig. 64.4); for example, one elevator cannot be started if a connected transporter was not previously started. The program is written in LD language because it must check all the conditions at every PLC cycle.
- *Loadxxx* programs manage the communication between the PLC and PC (written in SFC).
- The *mixing* program controls the necessary timing needed for the mixing process of the materials.
- The *extraction_supervisor* program supervises the extractions programs. It decides if and when an extraction should start.

Other programs manage the loading and unloading of oil and premix, calculate the average values of analogue signals, and so on. The project can work in two modes:

- *Manual* mode, where only specific commands can be given to some of the machines
- *Automatic* mode, where the production process is automatically managed by the PLC.

One of the major tasks to be efficiently implemented is the correct management of *timing*. The chosen solution was to use only one timer variable for all SFC-type programs that is started when automatic mode is chosen. In all SFC programs that need timing comparisons, the solution adopted was to read this *global timer* as necessary and make the desired calculations of time passed. Other tested solution, using special timing functions, like timer on (off) delay did not give expected results in SFC programs, but performed well in LD diagrams. When the automatic mode ends, the global timer is stopped and reset in order to avoid the situation in which the timer could reach its maximum and overflow. The timer is not needed in the manual mode.

Another special request was to minimize as much as possible the production time, in order to increase productivity. The solution chosen to achieve this goal was to extract the cereals immediately after weighing machine 1 is unloaded into the transporting system. In this way no time is lost; while the milling machine is prepared to receive material, the weighing machine 1 is emptied without any delay. In Fig. 64.4 an example is shown of how the timer-off delay function block is used in a LD program.

Because the impulse duration of variable b_SEL1_op (starts a motor rotating clockwise) is too short, it was extended by 500 ms. In the second line of the diagram you can see that the command is reset when:

- 500 ms has passed or the confirmation from the motor's contactor arrived.
- The motor reached the corresponding limit.
- Confirmation from the counterclockwise contactor is not active (failure situation).

In this way the operator must only start the movement of a motor and the controller automatically stops it when one of the conditions is fulfilled.

Another job to be correctly managed was the emergency status. Because of the nature of the installations of the factory, there are frequent situations when the product process must be immediately interrupted (extractor clogging, transporters stuck, and so on).

When an emergency occurs (that could not be detected automatically) the operator must stop all the processes immediately by simply clicking a button, implemented in the user interface. Inside the programs, almost all the steps verify the status of the emergency button and the status of several sensors. When an emergency is detected, all SFC programs stop in their current step. Depending on the gravity of the situation, the operator has the possibility to resume the process from the point where it was stopped or to reset all the programs (Fig. 64.5).

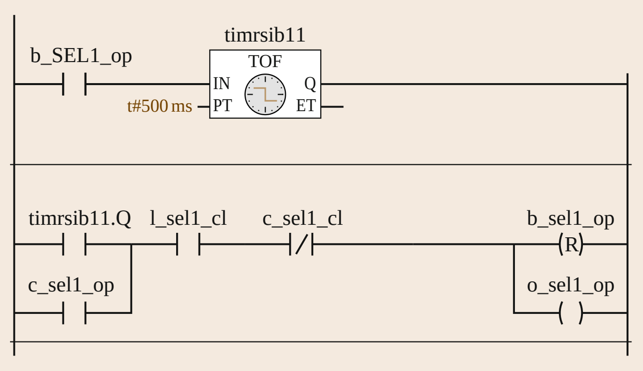

Fig. 64.4 Automatically stopping a motor in an LD program

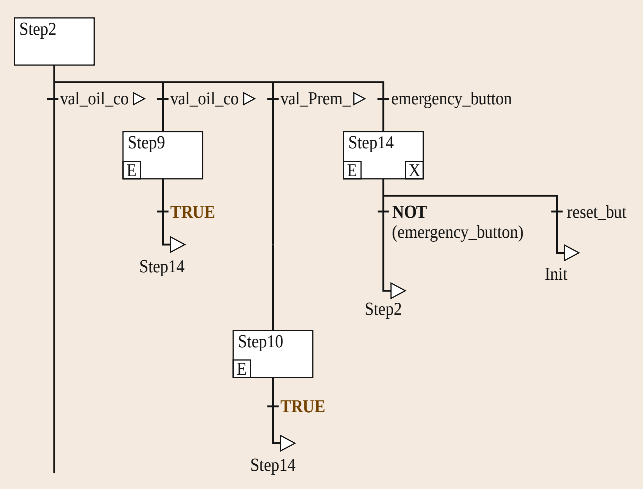

Fig. 64.5 Managing emergency situations in SFC

Once can see that step 2 has four conditions of transition. The first is the normal behavior of the process, conditions 2 and 3 appear when some material is missing in the bin, and the fourth is true when the operator presses the emergency button on the interface screen. The latter three transitions lead the program to an *emergency* step 14, from where the graph can evolve to step 2 (resuming the program) or the Init step, sending the program back to its initial status.

64.8 Communication

Usually PLCs communicate with a PC by means of a serial port (RS232 or RS485) or an Ethernet interface (usually available only in more expensive and newer PLCs). Various protocols are implemented in the PLC in order to communicate (such as Profibus, transmission control protocol (TCP)/internet protocol (IP) and others). Sometimes the programmer must develop his own communication protocol if none is implemented in the PLC.

ThinkIO controllers have already installed an OPC server that can be used to exchange data between the PLC and other computers connected in the same network. This is a very useful feature because several PCs can communicate with the controller and can be used to monitor all the production process, to configure the recipe, and even to send commands to the installations (if the program allows this).

At this time one PC program was developed, with the following behavior:

- The operator can edit, save, load recipes, and send them to the PLC on the network, acting as an OPC client.
- Reports are printed at the printer after each charge finishes.

64.9 Graphical User Interface on the PLC

In a Codesys development program the user can create as many visual interfaces as needd and run this interfaces directly from the ThinkIO PLC. Practically a PC is not needed anymore to supervise the control process.

For this project five visual screens were developed, each representing a specific area of the factory; for example Fig. 64.6 shows the main area of the factory, with its complicated transport system (formed by conveyors

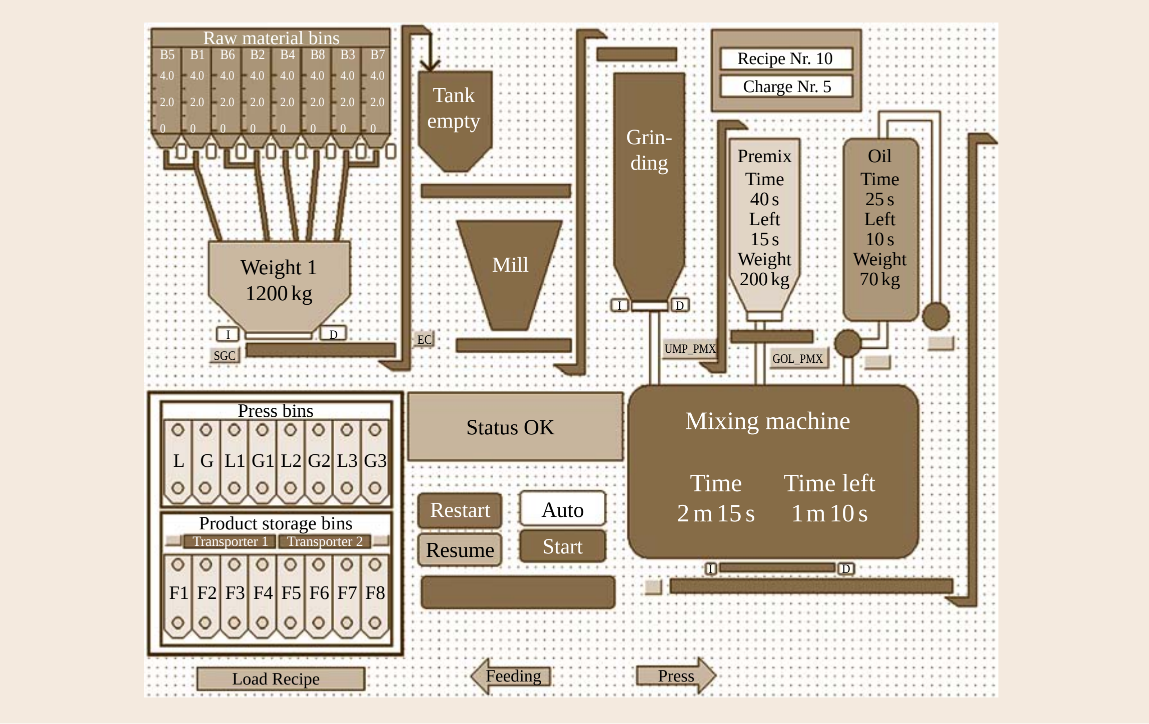

Fig. 64.6 Software view: main production area

and elevators), storage bins for raw material and final product, and other machines. Buttons on the screen can be clicked with the mouse and will start/stop some motors. The color of the objects usually indicates its status (started, stopped, full, empty, and so on), according to the values of associated sensors.

In this screen the operator can see information from all the sensors in the area, even the values from the weighing machines. Also the operator can manually command the execution elements from this area, e.g., can start automatic production or stop it by pressing the emergency button.

64.10 Automatic Feeding of Chicken

All this fodder production obtained in the feed plant is destined for feeding growing chicken in special farms. Chicken growth requires two separate processes: the supply of food and water to them and control of the environment. The chickens are prepared for sacrifice after 40 days, which is the optimum period for the chickens to be large enough and have tender meat. The control system of the factory must be very efficient in order to minimize the cost per kilo of meat. Two factors influence correct growth of chickens: food quality and environmental parameters (temperature and humidity). It is very important that the chicken do not waste energy adapting to the environment, so temperature and humidity control must be very accurate. Environment control strategy is different from summer to winter.

The process of supplying food and drink is not very complicated. There are sensors that check if there is food in the *plate*; when the plate is empty the control system starts the motors of the conveying system and stops them after a specific period of time. There is also an alarm system when the tank reaches a *lower limit* (Fig. 64.7).

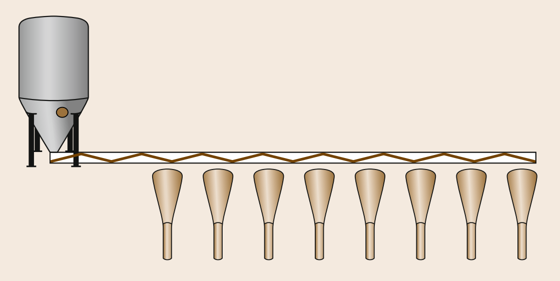

Fig. 64.7 The feeding system

64.11 Environment Control in the Chicken Plant

Environment control has to be the most accurate. Temperature and humidity must continually be maintained inside a specific range of values that differs from one day to another. To fulfil this, gas burners and fans are used to ventilate the interior with fresh air. To achieve a good distribution of temperature many small burners are used instead of fewer larger ones. Because the outside temperature differs between day and night, not all capacity of the fans is needed all the time. To adjust this, variable-frequency drive (VFD) speed control is used. A special situation occurs on cold days when, even with no fan speed, the air flow is too strong to maintain the temperature. There are three blowers and normally all of them have to work for a good dispersion of fresh air. Anyway there is the possibility to manually select the operation of each blower. Another option is to use dumpers in each fan to control the opening of the windows. The inside temperature is controlled by a proportional–integral–differential (PID) software algorithm combined with control of the dumpers when needed. This is a continuous process and above it there is a batch process that provides the set point for temperature controller according to a temperature diagram. Usually this system is sufficient also to keep O_2 within prescribed limits, but it is not sufficient for humidity all of the time. The behavior of the indoors environment is for increasing humidity, so controlled opening of windows succeeds in maintaining the desired conditions.

Here the processes are minor, but the combination of a continuous process with a batch one does not result in a simple system. The performance of controlling these parameters combined with the provision of appropriate food for each stage makes the difference between companies. Another important influence on system performance is the positioning of temperature sensors, which should be uniformly distributed throughout the area.

64.12 Results and Conclusions

There were two important requirements to be accomplished by this automation system:

1. The ratio between different components contained in a final product had to be very close to the programmed values (maximum 5% error).
2. The quantity of final product must also be close to the programmed total quantity (2–3% error was requested).

After several weeks of system testing the results were as follows:

- Condition 1 was fulfilled, and the error was very small (2%).
- Final quantity was about 5% more than the desired quantity, because of estimated extraction, small losses in transporting system, and so on.

The solution adopted was to slightly reduce the scales for calculating the weight values for the weighing machines until the resulted quantity was within approximately 2% of the desired value. At that time the automation could be declared finished, with very good results.

We believe that the solution chosen for this automated system is very modern and has several advantages over what one might call classical solutions using other PLC models [64.2]:

- Process control and supervision do not require a PC, as all programs and visual interfaces run on the PLC.
- Fast and reliable network communication with PCs, by OPC server, in contrast to the widely used serial RS232 or RS485 communication in other controllers.
- The short working cycle due to fast processor.
- The extremely large number of I/O modules that can be managed (hundreds of digital signals monitored) by a single controller.

Future work will be to design a supervising user interface program that can access the controller directly the from internet [64.3], so, e.g., the owner of the factory can be informed about production flow even when far from the factory.

65. Securing Electrical Power System Operation

Petr Horacek

Automation in power systems has a very long tradition. Just recall the flyball governor in a steam engine and it becomes clear that power people have been using control principles and instruments for more than a century. There are, however, new challenges in power generation and transmission concerning the security and efficiency of those services that require the attentions of both theoreticians and practitioners. These challenges are the subject of this chapter. The power failures that affect large grids from time to time show that system collapses are not simply a subject of academic debate. Power network operating reliability has become an issue that any country must make a top priority. The reliability of a power system depends for the most part on the quality of the decisions made, both automatically and manually. The term *power system* is very broad, and we focus here on the power system backbone, electric power transmission, and its operational reliability, particularly when automatic control plays a vital role. The content of the chapter remains interdisciplinary, spanning power systems, automation and economy, as changes resulting from the opening of the markets and permanent power system restructuring affect its operation.

There are several textbooks that survey the power industry – covering a regulated utility structure and the major concepts of deregulation, the history of electricity, the technical aspects, and the business of power – that are recommended for those who would like to get a broader picture of the industry [65.1].

Unlike other commodities, electricity generally cannot be stored for later use; it must be used as it is generated. Therefore, generation must be dispatched instantaneously to respond to real-time changes in consumers' demand for electricity. To support these energy flows, grid operation encompasses scheduling and managing flows over transmission lines and coordinating the operation of the transmission network equipment.

This chapter introduces methods for securing the operation of an electrical power system network, as

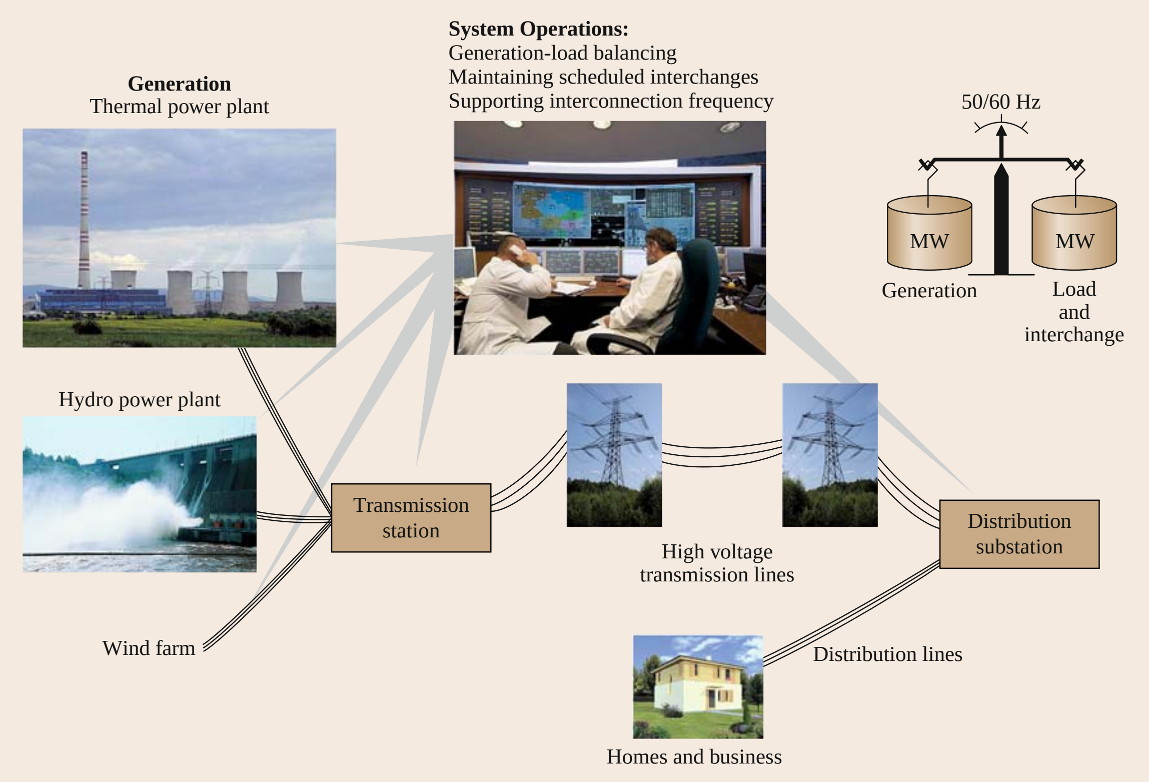

Fig. 65.1 Area system control objectives

shown schematically in Fig. 65.1, in terms of active power balancing through both automatic and manual interventions. Unlike a traditional control problem, where the task is to synthesize the control law for a given plant/process and constraints, our problem is to determine the constraints for a given control law so the control system has the right freedom in taking proper actions. Constraints appear in the form of regulating/balancing power reserves that have to be planned and reserved in advance so that the area control error, the instantaneous difference between the actual and the reference value for the power interchange of a control area (also known as the unintentional deviation), is kept within reasonable bounds. Balancing power is accessible in the form of ancillary services (AS), as provided by power-generating companies and traded in the market. Balancing power reserve activations are variables manipulated by a system operator (SO) which is responsible for power balancing in a geographical area. This is a complex task in a liberalized market environment. Power reserves, or rather the ancillary services providing the reserves, must be carefully planned and purchased so that the SO is able to use them when required.

The chapter introduces a power-balancing problem, starting from a review of the basic concepts of controlling synchronous generators connected to large grids, such as the technical means for power balancing that are available, how the power balancing is distributed throughout the network, and who is in charge of the task. Next, criteria related to the successful completion of the balancing task are revealed for two large grids: the North American and European grids. Later, the principle of a decision-support tool used by a SO for year-ahead planning and procurement of ancillary services is described. A method originally designed for the area of the UCTE, the *Union for the Co-ordination of Transmission of Electricity*, in which 23 European countries are synchronously interconnected, can be made applicable to other conditions after modification. Some of the challenges associated with continuously evolving power systems, where automation plays an important role, are discussed at the end.

65.1 Power Balancing

In any electrical system, the active power generation and consumption must be balanced to prevent major losses of material and even human lives, as large or long-lasting power deviations may ultimately lead to blackouts if the balance moves out of control. Disturbance to this imbalance, first noticed as a system frequency deviation, will be offset initially by the kinetic energy of the rotating turbo generators and motors connected to the grid. The capacity of kinetic energy storing elements is insufficient to maintain the power equilibrium in real time. Generation units must be manipulated to conduct power balancing so that the network user is not affected by demand changes or generation and transmission outages.

65.1.1 The Problem

Secure operation of a transmission system and prevention of blackouts is an issue of rising importance for countries with deregulated electricity markets. The liberalization of electricity markets is a process that started a while back and is still in progress in many countries [65.2–5]. The basic motivation for this liberalization is to enable more effective power generation as well as investment and expansion planning than would occur in a traditionally vertically integrated electricity supply industry. On the demand side, end users are free to choose their supplier and to negotiate their contracts. On the supply side, producers can sell their electricity to any other market players. It is believed that this could possibly result in lower electricity prices. However, links between physics and business practices must be carefully maintained to ensure that enough balancing power is available when required, so the performance criteria of the system is guaranteed at the lowest cost possible. In another words, there is the need for active power balancing mechanisms, reserve planning and purchasing, which is the task performed by a balancing authority (BA) responsible for power balancing in an area within the electrical grid.

The BA is an electrical power system or combination of electrical power systems bounded by interconnection metering and telemetering. The BA balances the supply and demand within its area, maintains the interchange of power with other balancing authorities, and maintains the frequency of the electrical power system within reasonable limits.

65.1.2 Who Performs Power Balancing?

All grid operators are charged with maintaining the reliability of the systems under their control. Within their footprints, SOs oversee and direct the high-voltage bulk-power system and coordinate electricity generation to maintain a reliable supply of electrical power to electricity users. SOs provide critical reliability services, including outage coordination, generation scheduling, voltage management, ancillary services provision, load forecasting, and more. They improve reliability in part because of their large scope – by consolidating control areas, they reduce the number of decision makers managing the grid, which simplifies coordination and improves reliability.

System operators oversee grid functions and make necessary corrections to ensure reliability on a minute-to-minute basis around the clock. SOs may organize wholesale markets for energy and ancillary services, such as reserves, frequency and voltage regulation, and voltage support. These ancillary services help ensure reliability and help system operators react quickly and effectively to changing conditions on the grid, such as the loss of a generating unit or a transmission line.

Independent system operators (ISOs) and regional transmission organizations (RTOs) in North America and transmission system operators (TSOs) in continental Europe have the size, scope, scale, tools, information and authority to be effective grid managers. ISOs/RTOs/TSOs have near-identical responsibilities for managing the grid over a large geographic scope and operating markets to some extent.

Anyone who would like to get more details on the definitions, terminology, responsibilities and procedures that a particular system operator should use an internet search engine and look for the key word *Grid Code*. The *Grid Code* is an industrial textbook that every system operator must follow every day; it is carefully and regularly updated.

North America

There are three synchronous areas in North America: the Western, Eastern and Texas Interconnections. In each interconnection there are ISOs (BAs) and local balancing authorities (LBAs) that communicate. As part of operating the grid, ISOs/RTOs meet or exceed the reliability standards set by the North American Electric Reliability Corporation (NERC) and its regional councils. Adhering to NERC standards ensures that the entire

Table 65.1 Classification of ancillary services

Generic AS	Description
Continuous regulation	Provided by online resources with automatic controls that respond rapidly to operator requests for up and down movements. Used to track and correct minute-to-minute fluctuations in system load and generator output.
Energy imbalance management	Serves as a bridge between the regulation service and the hourly or half-hourly bid-in energy schedules; similar to but slower than continuous regulation. Also serves a financial (settlement) function in clearing spot markets.
Instantaneous contingency reserve	Provided by online resources equipped with frequency or other controls that can rapidly increase output or decrease consumption in response to a major disturbance or other contingency event.
Replacement reserves	Provided by resources with a slower response time that can be called upon to replace or supplement the instantaneous contingency reserve in restoring system stability.
Voltage control	The injection or absorption of reactive power to maintain transmission system voltages within required ranges.
Black start	Generation is able to start itself without support from the grid and has sufficient real and reactive capability and control to be useful in system restoration.

grid in North America operates at appropriate levels of reliability.

The ISO calculates the area control error (ACE; described later in the chapter) for its balancing authority area and measures the ACE against the applicable balancing standards. There are also local balancing authorities that are responsible for actual interchange.

To summarize, the ISO assumes the role of a BA, planning authority, reliability coordinator, market operator and tariff and interconnection administrator. LBAs take care of load and resource asset management, tie-line checkout and emergency operation coordination. ISO guarantees effective use of assets, including the dispatch of energy and the dispatch of reserves (including contingency reserves). The ISO organizes the energy and operating reserve market (also known as the ancillary services market), regulation and response services, and contingency reserves.

Europe

In continental Europe there is an equivalent to the American ISO/RTO Council, the UCTE. The UCTE also defines standards the members must adhere to, so the UCTE plays the role of the NERC as well. The difference is that members of the UCTE are system operators that are each responsible for a single control area (synchronously interconnected within the UCTE) and own the transmission assets. In many countries, the transmission system operator (TSO) plays the role of the BA.

65.1.3 Means of Balancing

Power reserves are provided by generators and distributors in the form of ancillary services. By definition, ancillary services are interconnected operations services influencing transfer of electricity between purchasing and selling entities which a balancing authority must include in an open access transmission tariff.

Ancillary services are a collection of secondary services offered to help to insure the reliability and availability of energy to consumers. These services include regulation and contingency reserve (spinning, supplemental – nonspinning). The contingency reserve services are often referred to as operating reserves.

Ancillary services insure that capacity is available when needed to maintain secure power system operations due to a loss of or increase in load and resources.

A contingency is a trip of a transmission line or generator, a loss of load, or some combination of these events. This contingency in turn causes other problems, such as a transmission line overload, an over- or undervoltage in an area, over- or underfrequency, or frequency instability. Contingency reserves are a special percentage of generation capacity resources held back or reserved to meet emergency needs.

AS arrangements vary considerably across electricity markets. Let us introduce six generic AS that are necessary for maintaining system reliability and security in electricity grids. Ancillary services required during normal conditions are continuous regulation and energy imbalance management. Instantaneous contingency reserve and replacement reserve are services that are used during system contingencies. Ancillary services that do not apply to active power balancing directly are voltage support and black start. The generic AS categories are described more precisely in Table 65.1.

Ancillary service markets are critical to power system security and reliability and, given the value that customers place on reliable electrical services, their overall value to society is quite high.

Each market incorporates all six generic ancillary services, although the nomenclature, technical requirements and procurement details vary significantly. This chapter assumes that we are working with a TSO, and an area of the UCTE, in the European system, where transmission ownership and system operation is managed by a TSO as a single authority in the control area.

The role played by the TSO in the real-time power balancing can be understood from the overall block diagram in Fig. 65.2, which shows the essentials of the power balancing task while hiding the complexity of the very large scale power system. The control area in the center is synchronously connected to three adjacent areas A, B and C, making an interconnection.

The task for the TSO is to acquire enough power reserves in the form of ancillary services and activate them in a timely manner in order to guarantee the limits set on performance indices (standards) that evaluate the quality of power balancing. The task must be solved for the lowest cost possible. In this chapter, we define performance indices, describe the methods used in planning, and show how the planned reserves are validated. This chapter considers one year as the horizon for ancillary services planning.

65.1.4 Power Balancing Mechanisms Within the Control Area

What Is a Control Area?

A control area is an electrical power system that is managed under a common automatic control scheme

that maintains frequency by balancing load with production. Historically, a utility ran its own control area, regulating frequency, balancing load and generation, purchasing energy and capacity, and maintaining operating reserves as needed. Many large utility control areas served smaller in-area and nearby utilities as well. Today, some control areas exist to manage only generation, but most balance both generation and load. In North America, many control areas that existed historically have been consolidated into ISOs or RTOs and offer system balancing and management services that the control area no longer had to provide itself.

Power Balancing

To operate a large power system and to create suitable conditions for commercial electricity trade, it is necessary to schedule the power to be exchanged at the interconnection borders between the system operators in advance. During daily operation, the schedules are followed by means of the load-frequency control installed in each control area. Despite the functionality of load-frequency control, unintentional deviations occur in energy exchanges. For this reason, unintentional deviations are compensated for through methods of the TSO in every control area.

Real-time power balancing of a control area is usually performed by both automatic control and manual interventions from the TSO's dispatch center. The entire feedback control loop of a particular control area is shown in Fig. 65.3.

From the control theory perspective, the controlled variable is the instantaneous value of the cross-border power exchange P_{measured}, which should meet its scheduled value $P_{\text{programmed}}$. Manipulated variables are represented by various categories of regulation power available in the form of ancillary services. Disturbance variables influencing cross-border power exchange can be divided into two groups: deterministic, e.g., imbalances caused by trading strategies; and stochastic, mainly random demand fluctuations and generator outages.

The input to the controller is the ACE, the difference between the scheduled and actual cross-border power exchange, corrected for the effect of the primary frequency control so that the central controller does not compensate for outages of generators located in adjacent control areas (for example).

The output of the central controller is to increase or decrease power on the production side or, in the extreme case, on the consumption side as well. Despite the

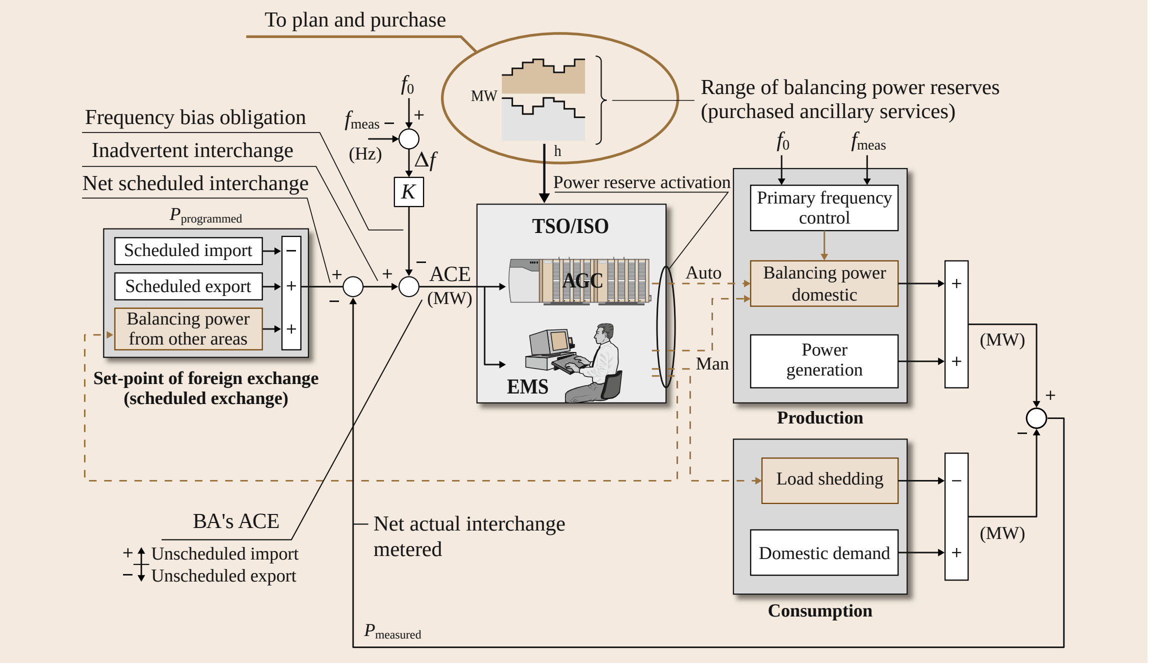

Fig. 65.3 Power balancing in the area as a feedback control system

Part G | 65.1

fact that the manipulated variable is active power, a single variable, we have to deal with a number of outputs due to the fact that there are many actuators with different characteristics spread throughout the power system. Different turbo generators have different control regions and dynamics. Some units are in a standby mode and it takes some time to start them up and reach synchronous speed. There are several modes in which the unit control system can run. Thus, each producer can offer the TSO a certain amount of reserve power in several categories of AS. The TSO defines the portfolio of ancillary services which might differ from country to country, state to state, or area to area, and runs an AS market where a TSO purchases balancing power reserves for potential use. Examples of AS we deal with in this chapter when explaining a method of AS planning are shown in Table 65.2.

Ancillary services that are activated automatically are primary and secondary controls. The functionality of primary frequency control, or rather activation of the active power reserve RZPR, is distributed throughout the control area, and is part of a speed governor control system operating in droop control mode.

Activation of the secondary power reserve is conducted by the central TSO's control system. This scheme is associated with the term *automatic generation control* (AGC), which means the automatic adjustment of a control area's generation from a central location to maintain its interchange schedule plus frequency bias. AGC is also known as a load-frequency controller. Generators under secondary control (UCTE) must reach the demanded increase/decrease in power output within 10 min at a rate of at least 2 MW/min.

The remaining AS, used predominantly for energy imbalance management and during contingencies, are dispatched by the TSO manually.

Let us define basic terms before describing the methodology for AS planning.

65.1.5 System Frequency

The electrical frequency in the network, the system frequency f, is a measure of the rotation speed of the synchronized generators. As the total demand increases, the system frequency will decrease, and vice versa. The turbine speed controller performs an automatic primary control action to balance demand and generation. The frequency deviation Δf is influenced by both the total inertia in the system and the speed of primary control. Under undisturbed conditions, the system frequency must be maintained within strict limits in order to ensure the full and rapid deployment of control facilities in response to a disturbance.

65.1.6 Primary Frequency Control

The objective of primary frequency control (PR) is to maintain a balance between generation and consumption within the synchronous area using turbine speed governors. PR is an automatic function distributed throughout the network. When the generator is part of a large power system, and electrical power generation is shared by two or more machines, the frequency (speed) cannot be controlled such that it remains constant because it would forbid generation sharing between various synchronous generators. Control with speed droop is the solution that allows for fair generation sharing.

PR stabilizes the system frequency in seconds after a disturbance. In principle, the control law is proportional and the controlled system does not have integral character. The result is the steady state error in system frequency and, in addition, scheduled power exchanges between areas are not restored. Through the joint action of all primary controllers, PR ensures the operational reliability of the power system of the synchronous area. It stabilizes the frequency, but cannot drive the system

Table 65.2 Examples of ancillary services and their categories

Generic AS		Preferred use	Area-specific AS identifier	Response time
Continuous regulation	Spinning	Primary frequency control	RZPR	≈ 30 s
Continuous regulation	Spinning	Secondary power and frequency control	RZSR	≤ 15 min
Energy imbalance management	Spinning	Load following	RZTR^{+} RZTR^{-}	≤ 30 min
Instantaneous contingency reserve	Nonspinning	Operating reserve	RZQS	≤ 15 min
Replacement reserve	Nonspinning	Dispatch reserve	$\text{RZN}_{>30}$	> 30 min

frequency back to the original setpoint value and cannot restore cross-border power exchanges in the interconnected system, so they will differ from the values agreed between parties.

The overshoot or undershoot of the system frequency is a function of the amplitude and dynamics of the disturbance affecting the balance between power output and consumption, the kinetic energy of rotating machines in the system, the number of generators subject to PR (i. e., the primary control reserve and its distribution between these generators), the dynamic characteristics of the machines and their control systems, and the dynamic characteristics of loads, particularly the self-regulating effect of loads.

The steady state error of the system frequency is a function of the amplitude of the disturbance and the gain of the proportional controller, which is associated with the so-called network power system frequency characteristic.

Starting from undisturbed operation of the UCTE network [65.6], a sudden loss of 3000 MW of generating capacity must be offset by primary control alone, without the need for customer load-shedding in response to a frequency deviation. In addition, when the self-regulating effect of the system load is assumed to be 1%/Hz, the absolute frequency deviation must not exceed 180 mHz. Likewise, the sudden load-shedding of 3000 MW in total must not lead to a frequency deviation exceeding 180 mHz.

The primary control reserve for the entire synchronous area RZPR, also referred to as a continuous regulation reserve, is determined by the required performance described above, taking into account measurements, experience and theoretical considerations. The share RZPR_i of the control area i is defined by multiplying the calculated reserve for the synchronous area and the contribution coefficient C_i of the control area

$$\mathrm{RZPR}_i = \mathrm{RZPR}\,C_i\;, \tag{65.1}$$

where the contribution coefficient C_i is calculated on a regular basis for each control area or TSO using

$$C_i = \frac{E_i}{E}\;, \tag{65.2}$$

where E_i is the electricity generated in control area i and E is the total electricity produced in all control areas of the synchronous interconnection.

A deviation in system frequency Δf will, in the steady state, release primary control power throughout the synchronous area ΔP_{PR} as

$$\Delta P_{\mathrm{PR}} = \lambda \Delta f\;, \tag{65.3}$$

where the gain λ is called the power system frequency characteristic of the synchronous area and λ is the sum of the power system frequency characteristics of all areas that are synchronously connected.

Each TSO is required to maintain a network power-frequency characteristic λ_i of the control area that is derived from the power-frequency characteristic designed for the overall synchronous area λ and the area contribution coefficient C_i

$$\lambda_i = C_i \lambda\;. \tag{65.4}$$

Each interconnected TSO must activate primary control power that is adequate for the system frequency deviation Δf using

$$\Delta P_{\mathrm{PR}\,i} = \lambda_i \Delta f\;, \tag{65.5}$$

where $\Delta P_{\text{PR}\,i}$ is the power variation generated locally in the control area in response to a frequency deviation caused by a disturbance (e.g., generation unit outage).

Figure 65.4 shows the principle of the primary control loop for the area. Note that the index of the area i is omitted from all power variables and λ for simplicity. The block diagram should actually be split further into control loops of individual turbo generators, as shown in Fig. 65.5. Generating units should deliver programmed (contracted) active power and provide power balancing functionality through primary, secondary and tertiary control at the same time. The programmed power is thus modified locally by primary frequency control independently of all other methods of power balancing used centrally by the TSO.

Primary control is performed by the speed governors of the generating units. With primary control, a variation in system frequency that is greater than the dead band will result in a change in unit power generation. Generators are required to participate in this control by setting the droop, which is directly related to the gain of the speed governor in Fig. 65.5, according to specifications defined by the TSO. Transients of primary control have a timescale of seconds.

Power engineering is an area where different disciplines use different words for the same function, and many power engineers get frustrated when the literature fails to define or mention the terms *droop*, *isochronous* or *speed/load*, which refer to generator control [65.7]. Here are a few examples.

Rotating equipment people refer to *droop* control. The governor droop characteristic of a generation unit is given by the frequency deviation (% with respect to the nominal frequency) needed to change the generation power output (% with respect to nominal output) multiplied by 100. For example, a 5% droop means that a 5% frequency deviation causes a 100% change in power output. However, controls or instrumentation specialists would call this *proportional* control and might not even recognize the term *droop*. Frequently, utilities or powerhouse people will refer to this as *speed/load* control and may not recognize either of the other terms.

By the same token, people with a rotating equipment background will refer to *isochronous* control. Control engineers will call this PID control, and utilities or pow-

erhouse people will use the terms *frequency* or *speed* control to refer to the same thing.

The synchronous generator is operated in frequency (isochronous) control mode when disconnected from the grid and is switched to droop control when synchronized and connected to the grid. On a small electrical grid, one machine is usually operated in isochronous speed control mode, maintaining the system frequency using a PID control loop. Any other (usually smaller) generators that are connected to the grid are operated in droop speed control mode, running under P control. If two prime movers operating in isochronous speed control mode are connected to the same electrical grid, they will usually *fight* to control the frequency, and wild oscillations of the grid frequency usually result. Only one machine can have its governor operating in isochronous speed control mode for stable grid frequency control when multiple units are being operated in parallel.

In very large electrical grids, commonly referred to as *infinite* electrical grids, there is no single machine operating in isochronous speed control mode that is capable of controlling the grid frequency, and all of the prime movers are operated in droop speed control mode. However, there are so many of them and the electrical grid is so large that no single unit can cause the grid frequency to increase or decrease by more than a fraction of a percent as it is loaded or unloaded.

Very large electrical grids require system operators to quickly respond to changes in load in order to control grid frequency properly, since there is no isochronous machine that does so. Usually, when things are operating normally, changes in load can be anticipated and additional generation can be added or subtracted in order to maintain tight frequency control.

65.1.7 Secondary Frequency and Power Control

Secondary control (SR) drives the system frequency and cross-border power exchanges back to the original desired (programmed) values after 15–30 min if the activated power does not reach the saturation limit of the reserve acquired. To prevent saturation and loss of secondary control functionality, additional power should be released to the system by activating reserves other than the primary balancing power reserves.

Transients of secondary control are on the order of minutes. Secondary control is also called AGC. In addition, AGC distributes the imbalance between selected units in an economical way. AGC is usually provided by the area's balancing authority, the TSO in the case of UCTE interconnection. Generation scheduling and control is an important component of daily power system operation. The overall objective is to control the electrical output of generating units in order to supply the continuously changing customer power demands in an economical manner. Much of this functionality is provided by AGC as run by the balancing authority (TSO) and related functions operating within a utility control center energy management system (EMS).

Figure 65.6 shows a block diagram of the automatic SR control system, the function of which is realized by the TSO.

The output signal of the secondary PI controller ΔP_{SR} is distributed over participating generators with participating factors $\alpha_1, \ldots, \alpha_n$.

The function of SR, also known as load-frequency control or frequency-power control, is to keep or to restore the power balance in each control area, and consequently, to keep or to restore the system frequency f to its set-point value and the power interchanges with adjacent control areas to their programmed, scheduled values. This will ensure that the full reserve of primary control power RZPR will be recovered.

Whereas all control areas of the interconnection participate in providing primary control power, only the control area affected by a power imbalance is required to undertake secondary action for the correction. Parameters for the secondary control schemes are set such that only the controller in the zone affected by the disturbance concerned will respond and initiate the deployment of the requisite secondary control power. Within a given control area, the demand should be covered at all times by electricity produced in that area, including electricity imports (under purchase contracts and/or electricity production from jointly operated plants outside the zone concerned). Secondary control is applied to selected generator units in the power plants comprising the control loop.

Since it is technically impossible to guard against all random variables affecting production, consumption or transmission, the volume of reserve capacity will depend upon the level of acceptable risk. These principles will apply regardless of the distribution of responsibilities between the parties involved in supplying electricity to consumers.

In order to determine whether power interchange deviations are associated with an imbalance in the control area concerned or with the activation of primary control power, a corrective term should be introduced into the power interchange deviation. This is known

as the network characteristic method, and its function is shown through the K-factor link displayed in Fig. 65.6. Due to the uncertainty in the self-regulating effect of the load, the K-factor K_j may be chosen to be slightly higher than the rated value of the power system frequency characteristic λ_j, such that the SR will accentuate the effect of the PR. Each control area is equipped with one secondary controller to minimize the ACE in real time:

$$\begin{aligned}\text{ACE} = {} & P_{\text{programmed}} - P_{\text{measured}} \\ & - K\left(f_0 - f_{\text{measured}}\right) ,\end{aligned} \tag{65.6}$$

where P_{measured} is the sum of the instantaneous measured active power transfers on the tie-lines, $P_{\text{programmed}}$ is the exchange program with all the adjacent control areas, K is the K-factor of the control area, a constant (MW/Hz), f_0 is the setpoint, and f_{measured} is the instantaneous measured system frequency.

The ACE is the control area's imbalance $P_{\text{programmed}} - P_{\text{measured}}$ with the hidden effect of the area's primary control. A different sign convention may be used for ACE relative to the respective TSO. In this chapter, the power transits are considered positive for export and negative for import. Hence, a positive (a negative) ACE requires an increase (a decrease) in the secondary control power. The ACE must be kept close to zero in each control area at all times.

The secondary controller is implemented as a PI controller with additional features such as anti-wind-up and rate limiting.

The secondary control range RZSR is the range of adjustment of the secondary control power ΔP_{SR} within which the secondary controller can operate automatically in both directions (positive and negative).

In control areas of different sizes, load variations of varying magnitude must be corrected within approximately 15 min. The size of the RZSR required depends on the typical load variation, schedule changes, and generating units. The minimum value for the RZSR related to load variations in MW, recommended in UCTE, is obtained using the empirical formula

$$\text{RZSR} = \sqrt{aL_{\max} + b^2} - b , \tag{65.7}$$

where $L_{\max}$ is the maximum anticipated load in MW for the control area, and the parameters a and b are established empirically, with the following values used by the UCTE: $a = 10\,\text{MW}$ and $b = 150\,\text{MW}$.

If consumption exceeds production for longer periods, immediate action must be applied using tertiary control, standby supplies, or contractual load shedding as a last resort.

Secondary reserve is also referred to as continuous regulation reserve.

65.1.8 Tertiary Reserve

The active power ΔP_{TR} of a tertiary reserve RZTR is usually activated manually by the TSO to free up an exhausted secondary reserve so that it can effectively reject common fluctuations. Tertiary control action involves a signal being sent by the TSO to a producer whose generating unit is included in the tertiary control scheme requesting that the control range of the unit should be changed (e.g., by changing the operating point of the boiler). This usually takes some time, and the frequency of such actions is also limited. The function of the tertiary control can be viewed as a dynamic change in the active power setpoint, which in turn moves the use of the secondary control reserve away from its limit value. The reserve denoted RZTR^{-} is used to decrease the output and RZTR^{+} to increase the output.

Tertiary control is an economic dispatch. It is used to drive the system as economically as possible and restore security levels if necessary.

The AS provider must provide the requested portion of the regulating reserve within a specified time limit (e.g., 30 min) and at a specified minimum rate, typically 2 MW/min.

The tertiary reserve is a load-following spinning reserve.

65.1.9 Quick-Start Reserve

The quick-start reserve (RZQS) is usually provided by pumped-storage power stations that are able to start generation within 10 min. The preferred use of RZQS is to compensate for large and sudden deviations due to generator outage. This reserve is activated manually from the TSO's control center. As the capacity of water reservoirs is limited, the use of the quick-start reserve is restricted in time.

The quick-start reserve is also referred to as the contingency nonspinning reserve.

65.1.10 Standby Reserve

The standby reserve (RZDZ) is typically represented by combined-cycle gas-turbine generation units. Depending on their ability to reach nominal output within the agreed time, they may be in the category RZN_{30}^{+} or $\mathrm{RZN}_{>30}$. The standby reserves are typically activated in the case of a generator outage or a longer-lasting deficit of energy in the system caused by some other reason.

The standby reserve falls into the category of a contingency replacement (supplemental) reserve.

65.1.11 Planning Reserves

There are lots of constraints that must be considered when planning reserves. The following nonusable capacity must be taken into account when calculating the capacity needed to meet power requirements: units subject to long-term shutdown; units shut down for repair and maintenance; limits on capacity associated with restrictions in fuel supplies; limits on capacity associated with environmental restrictions; limits on the capacity of hydroelectric plants associated with hydraulic and environmental constraints; the primary control reserve; reserves to cover variations in production and consumption (secondary and tertiary reserves).

In addition to these factors, which are directly associated with production, system conditions must also be considered, given that network constraints may limit the transmission of the power produced.

From the TSO point of view, the support system for AS planning should read the reliability requirements for power balance control and provide recommendations for the optimal composition of the AS, which the TSO should then acquire on the market. In particular, the system should be able to answer the following questions:

- What amount of reserves in the form of AS is needed in each category to insure that power balancing is realized with the desired reliability?
- What can providers of AS on the market be expected to offer in terms of their volumes and prices?
- How should the AS be selected based on the offer to insure that the requirements are covered in the optimal way?
- What are the expected costs associated with a certain level of operational reliability of the transmission system?

Similar tasks have emerged in all countries that have gone or are going through the liberalization process. From a global perspective, the safe operation of a transmission system can be viewed as a multicriteria optimization task. Due to a strong interaction between the technical and economic consequences of the planning and operating decisions, the two basic competing criteria – quality of electricity and costs of operating the transmission system – must be considered simultaneously.

Optimal planning of the AS involves market modeling [65.3]. Three main modeling trends can be identified: optimization models, which focus on a profit maximization problem for one of the players competing on the market; equilibrium models, which represent the overall market behavior, taking into account competition amongst all participants; and simulation models, often based on multiagent systems, which are an alternative to equilibrium models in cases where the problem under consideration is too complex. The models use a variety of computational techniques: linear programming, mixed integer programming, dynamic programming, nonlinear programming, heuristic approaches, and others.

Many papers focus on the pricing and optimal procurement of the energy and AS. If the market products (energy and AS) are procured simultaneously through central (usually day-ahead) auctions, the task to solve is to simultaneously co-optimize energy and AS ensuring that costs are minimized but safe operation of the transmission system is retained. This involves addressing issues such as optimizing power flow, unit commitment, congestion management and emission constraints [65.4–8]. The products on the market may be procured sequentially through central auctions managed by the ISO/TSO, usually in the following order: energy market, transmission market to resolve congestions (if needed), and market for each category of the AS (from the fastest-responding to the slowest-responding service). In such cases, the problem of how to optimally purchase AS taking into account the downward substitutability of the AS arises, since the market clearing price in each market depends on the volume required. A rational buyer's algorithm described in papers [65.9, 10] can handle this problem.

However, the complex task of optimally planning AS is still a challenging one. Although methods solving some of the partial subtasks exist, they must be carefully chosen and modified to fit in the context of a specific country or region. The inner structure of the global AS planning problem may also vary from country to country.

Let's assume that the generation portfolio of a particular control area consists of dozens of 110 MW and 200 MW generation units, some 500 MW and 1000 MW generation units, and that the peak load is approximately 11 GW. Let's also assume a dense network so that no inner flow congestion management is needed; capacity auctions will only be organized for cross-border tie-lines.

This control area is part of the European synchronous interconnection (UCTE), and as such its operation must comply with the UCTE rules [65.6] and relevant legislation, which (among others) states the liability of the TSO for frequency and power balance maintenance. For this purpose, the TSO purchases most of the AS through free-market tenders organized typically for three-year and one-year periods. The TSO only spends money on reserving the AS (purchase); the costs of AS activation are covered later by the market participants that cause the power imbalance. Hence, for the rest of the chapter, when we refer to the cost of AS, we mean the cost of reserving the AS.

Energy markets are separate from AS markets. Most energy is traded in the form of bilateral contracts for base-load products on a year-ahead basis. Peak-load products are mainly associated with short-term energy markets. We assume that the TSO is not allowed to participate in energy markets.

65.1.12 Performance Criteria

Different interconnections may have chosen and use slightly different performance criteria to evaluate the reliability of system services in terms of power balancing.

The North American Electric Reliability Corporation (NERC) defines three control performance standards (CPS) for the assessment of control area generation control performance: CPS1, CPS2 and DCS [65.11]. All control areas in North America implemented CPS in 1998.

CPS1. Each balancing authority operates such that, on a rolling twelve-month basis, the scaled average of clock-minute averages of the ACE of the area multiplied by the corresponding clock-minute averages of the interconnection's frequency error is less than a specific limit. The index of the area i will be omitted for the rest of the chapter for simplicity, as our discussion only concerns a single area of the interconnection.

CPS1 is a statistical measure of ACE variability. CPS1 measures ACE in combination with the interconnection's frequency error. CPS1 requires that the average of the clock-minute averages of a control area's ACE over a given period divided by its K factor multiplied by the corresponding clock-minute averages of the frequency error should be less than a given constant

$$\mathrm{AVG}_{\mathrm{Period}}\left(\frac{\mathrm{ACE}}{K_{\mathrm{area}}}\Delta f\right) \le \varepsilon_1^2\,. \tag{65.8}$$

The constant ε_1 is derived from the targeted frequency bound (the targeted RMS value of one-minute average frequency error based on frequency performance over a given year). For the purpose of control performance evaluation, CPS1 is evaluated monthly for the previous (sliding) twelve-month period.

CPS1 measures control performance by comparing how well a control area's ACE performs in conjunction with the frequency error of the interconnection. Equation 65.8 can be viewed as a correlation between ACE and Δf. Positive correlation means undesirable performance (the area control error contributes to the frequency deviation from the desired value) and is therefore limited by the upper bound ε_1^2. Negative correlation occurs when ACE helps to compensate the total ACE of the interconnection and is helping to offset the system frequency deviation.

CPS2. The other criterion, CPS2, is designed to bound ten-minute ACE averages and provides an oversight function to limit excessive unscheduled power flows that could result from large ACE

$$\mathrm{AVG}_{10\_\mathrm{minute}}(\mathrm{ACE}) \le \varepsilon_{10}\sqrt{K_{\mathrm{area}}K_{\mathrm{interconnection}}}\,, \tag{65.9}$$

where $K_{\mathrm{interconnection}}$ is the sum of the K factors in the entire interconnection and ε_{10} is the targeted RMS of the ten-minute average frequency error. Each balancing authority operates such that its average ACE for at least 90% of the ten-minute periods (six nonoverlapping periods per hour) during a calendar month is within a specific limit, referred to as L_{10}. Extensive analysis and further discussions of the two performance indices can be found in [65.11–14].

NERC does not have the statutory authority to enforce compliance with its reliability standards. Despite its lack of authority, NERC has made every effort to continuously clarify and upgrade its reliability standards as the electrical power industry has evolved. NERC has also enhanced the monitoring of compliance with its standards by individual entities, independent system operators, and regional reliability councils.

Each control area can meet the CPS standards by any means they wish. A control area can potentially use current control schemes, meet its generating obligations manually, or implement other control schemes.

A control area that does not meet the CPS is not allowed to sell control services to other parties external to its metered boundaries. This impacts the purchasing control services from this control area. This is a significant penalty given new operating environments.

Benefits of CPS include the fact that it is technically defensible, allows smarter control by reducing unit maneuvering, provides more accurate assessment of control area performance, reduces generating unit operating and maintenance costs, provides the ability to monitor and control frequency performance, and allows less restrictive short-term performance requirements in exchange for more restrictive long-term requirements.

Disturbance Control Standard (DCS). The purpose of the disturbance control standard (DCS) is to ensure that the balancing authority is able to utilize its contingency reserve to balance resources and demand and return interconnection frequency within defined limits following a reportable disturbance. Because generator outages are far more common than significant losses of load, and because contingency reserve activation does not typically apply to the loss of load, the application of DCS is limited to the loss of supply and does not apply to the loss of load.

A disturbance is defined as any event that is $\ge$ 80% of the magnitude of the control area's most severe single contingency. A control area is responsible for recovering from a disturbance within 10 min by recovering the amount of the disturbance or returning ACE to zero. A disturbance is not reportable if it is greater than the control area's most severe contingency.

The control area must comply with the DCS 100% of the time. Any control area that does not comply is required to carry an additional contingency reserve. The extra reserves must be carried for the quarter following the quarter in which the noncompliance occurs.

Europe (UCTE)

According to the UCTE Operation Handbook [65.6], the individual ACE_i needs to be controlled to zero on a continual basis in each control area. In addition, the frequency deviation should decay to the given setpoint in less than 15 min, and any power outage should be compensated for accordingly. Both large and/or long-lasting ACE deviations should be avoided as much as possible.

These general quality requests will be specified in a more rigorous way in Sect. 65.2.2 when working with one-minute and one-hour averages of ACE, $\mathrm{AVG}_{1\_\mathrm{min}}(\mathrm{ACE}) = \mathrm{ACE}_1$, $\mathrm{AVG}_{1\_\mathrm{h}}(\mathrm{ACE}) = \mathrm{ACE}_{60}$ and other indices, so that it can be used as performance criteria and power balancing quality indices. The soft constraints L_1 and L_{60}, similar to L_{10} for NERC's CPS2, will be used.

Some of the requests can be represented as a mean value of ACE that should be kept at zero and a standard deviation of ACE that should be kept low. The mean and the standard deviation of the ACE is sometimes used to compare the operations of control areas in a single interconnection [65.15].

Setting the limit values of the selected performance indices is a delicate task. In general, if the limits are set too high, larger and/or longer-lasting power imbalances are assumed to be allowed. On the other hand, setting the limits too low may request an amount of balancing power reserve that is simply not available in the respective category in the area, and/or reserving that power will become too expensive.

In the following section, the task and the principle of the algorithm for AS planning is described.

65.2 Ancillary Services Planning

Each ISO/TSO can adopt different AS planning procedures depending on the interconnection and control area specificity. Recent changes in market structures make the problem more difficult, since there is a lack of long-term experience in effective AS planning. The principles, various criteria and constraints adopted in the method described in this section may serve as the basis for a general platform, despite the fact that the approach was developed for one control area in the UCTE interconnection. The method is currently being used by the TSO of the Czech Republic as a support tool and is described in [65.16] in greater detail.

The entire AS planning task can be decomposed into several subtasks (as depicted in Fig. 65.7) that are executed in the order indicated by the respective block numbering.

The control area is viewed as a pool. First, the ACE of the area is modeled as if it would run without AGC and EMS actions used centrally by the TSO (Step 1). Various horizons may be considered. One year is assumed for the reminder of the chapter. The variability of such an *open-loop ACE* is high. Considering the control and disturbance performance standards, the request for AS to decrease ACE variability is calculated

Fig. 65.7 Block diagram of ancillary services planning and validating procedures

(Step 2). If the availability of the AS is not limited and the cost of the AS is not an issue, the algorithm proceeds in running a Monte Carlo simulation of the area (Step 6) that includes TSO's AGC and EMS actions, and gets ACE statistics. Once the ACE time series has been obtained, any performance indices and conditions introduced by respective standards can be evaluated, including NERC's CPS2 and DCS.

In reality, AS is a commodity and the TSO must go to the market, compare the offerings to what is needed to meet the performance standards, and consider the AS price when purchasing. The initial plan for AS may not then be feasible, as some of the services needed may not be offered in sufficient amounts. However, there is some freedom to restructure the needs, as some faster services can be substituted for slower ones. This leads to a linear programming problem with the aim of minimizing the cost of the purchase and meeting the performance standards at the same time. AS bids are calculated (Step 3) and the optimal purchase is made, replacing the originally assumed set of AS by the feasible and cost-optimized one (Step 4).

The next sections briefly review the procedure. More details can be found in [65.16, 17].

65.2.1 Stochastic Model of Area Control Error

The *open-loop ACE* is considered a random process with characteristics related to the recent history of control area operation. The open-loop ACE $\mathrm{ACE}_{\mathrm{OV}}$ can be decomposed into two components

$$\mathrm{ACE}_{\mathrm{OV}} = P_{\mathrm{V}} + \mathrm{ACE}_{\mathrm{O}} \,. \tag{65.10}$$

P_{V} represents forced generation unit outages and will be modeled as a Markov process parameterized by mean time between failures and duration of repairs.

$\mathrm{ACE}_{\mathrm{O}}$ accounts for other phenomena, for instance a mismatch between load and generation, and is modeled as a stochastic process with a Gaussian distribution. A historical time series $\mathrm{ACE}^{\mathrm{H}}_{\mathrm{O}}$ is reconstructed from measured data as

$$\begin{aligned}&\mathrm{ACE}^{\mathrm{H}}_{\mathrm{O}}(t) = \mathrm{ACE}^{\mathrm{H}}(t) + \sum \mathrm{AS}(t)\,,\\ &\forall t : P^{\mathrm{H}}_{\mathrm{V}}(t) = 0\,,\end{aligned} \tag{65.11}$$

where $\mathrm{ACE}^{\mathrm{H}}$ is the measured ACE, $P^{\mathrm{H}}_{\mathrm{V}}$ are recorded forced generation units outages, and $\sum$ AS denotes the sum of all activated ancillary services at the time instant t. $\mathrm{ACE}_{\mathrm{O}}$ represents open-loop ACE in undisturbed conditions only. Then the statistical parameters of $\mathrm{ACE}_{\mathrm{O}}$ are evaluated from $\mathrm{ACE}^{\mathrm{H}}_{\mathrm{O}}$. A convolution between the probability density functions of $\mathrm{ACE}_{\mathrm{O}}$ and P_{V} results in the probability density function of the open-loop ACE, $\mathrm{ACE}_{\mathrm{OV}}$ (Fig. 65.8), which shows the performance of the control area in terms of how frequently a particular magnitude of the ACE appears in relation to the total number of observations. As shown, the positive part of the function is modulated by the forced generation unit outages.

The component $\mathrm{ACE}_{\mathrm{O}}$ can further be decomposed into a *slow component* $\mathrm{ACE}_{\mathrm{O\_slow}}$, which represents *low-frequency* content with a quasi-period of 10–30 min corresponding to trend changes in $\mathrm{ACE}_{\mathrm{O}}$, and a *fast component* $\mathrm{ACE}_{\mathrm{O\_fast}}$, which represents *high-frequency* noise with a quasi-period of several minutes caused by common fluctuations in the system

$$\mathrm{ACE}_{\mathrm{O}} = \mathrm{ACE}_{\mathrm{O\_slow}} + \mathrm{ACE}_{\mathrm{O\_fast}} \,. \tag{65.12}$$

This decomposition will be used later when determining AS needs, because each of the components is compensated by a different type of AS. The $\mathrm{ACE}_{\mathrm{O\_fast}}$ is calculated from $\mathrm{ACE}^{\mathrm{H}}_{\mathrm{O}}$ as a moving hour average, and the remaining *noise* represents $\mathrm{ACE}_{\mathrm{O\_slow}}$. Finally, the open-loop area control error $\mathrm{ACE}_{\mathrm{OV}}$ is a sum of slow and fast variations of $\mathrm{ACE}_{\mathrm{O}}$ plus forced generator outages

$$\mathrm{ACE}_{\mathrm{OV}} = \mathrm{ACE}_{\mathrm{O\_slow}} + \mathrm{ACE}_{\mathrm{O\_fast}} + P_{\mathrm{V}} \,. \tag{65.13}$$

More details on the stochastic model of ACE can be found in [65.17].

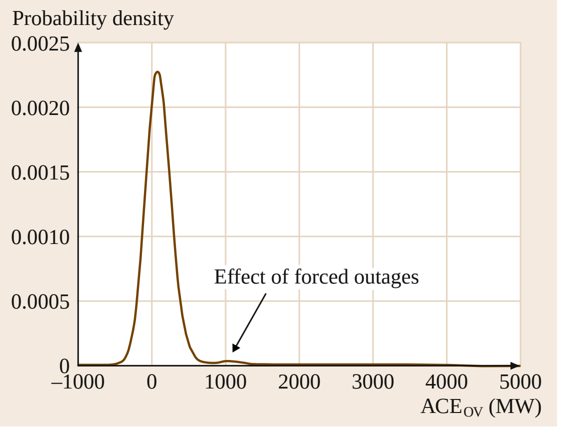

Fig. 65.8 Probability density function of $\mathrm{ACE}_{\mathrm{OV}}$

65.2.2 Minimal Needs of AS

In order to determine the power reserves in the form of AS that would technically suffice for proper power balance control with acceptable reliability, it is necessary to refer to reliability standards. Since the UCTE has no specific reliability standards for its members [65.18], seven indices describing reliability are defined in Table 65.3 for this purpose. Each of them represents a probability that ACE exceeds a certain threshold and lasts for a certain amount of time (value at risk). The index $r\mathrm{ACE}_1$ refers to the one-minute average value of ACE, while the index $r\mathrm{ACE}_{60}$ refers to an average value of ACE over 1 h.

The indices $r\mathrm{ACE}_1$ and $r\mathrm{ACE}_{60}$ are statistical measures of ACE that are related to NERC's CPS2. $r\mathrm{ACE}_{1t}$ is linked to the UCTE requirement for frequency recovery in less than 15 min after a forced generation unit outage, and thus it is similar to NERC's DCS index. The other indices ($r\mathrm{ACE}_{60\,tx}$) indicate the possible danger of a longer-lasting power imbalance that may lead to an application of load-shedding mechanisms or to a blackout in the worst case.

The desired values were determined statistically from historical records of ACE. A few consecutive years should be evaluated. The duration of the period assigned for statistical evaluation should correspond to a period when the technical parameters of the transmission system and the market conditions are compatible with the current situation and practices. In addition, no problems related to the area performance should be reported from either TSOs in adjacent areas or from domestic customers. Hence, we can assume that the TSO's performance was satisfactory.

The indices are direct measures of the quality of power balance control in the control area, and indirect measures of the reliability of the power supply to end-consumers.

The AS categories considered throughout the chapter are described in Table 65.2. Analytical computations of the minimal AS needs are based on the stochastic characteristics of ACE and its components, as determined in Step 1. Regarding the fact that some of the AS are mutually substitutable (i. e., faster-responding services such as secondary control can be substituted for slower-responding services such as tertiary control),

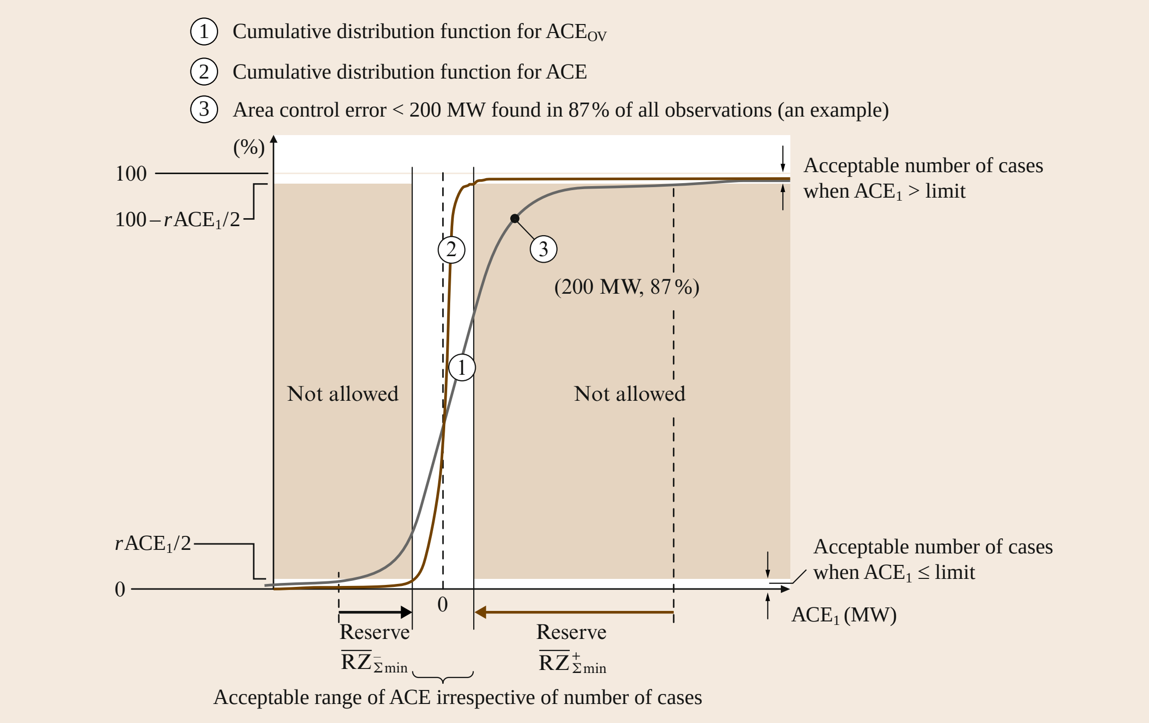

Fig. 65.9 Cumulative distribution function of the open-loop ACE and its use

Table 65.3 Reliability indices based on area control error time series evaluation

Performance index	Limit value (%)	Description
$r\mathrm{ACE}_1$	3.2	Probability that the absolute value of the one-minute average of ACE exceeds $L_1 = 100\,\mathrm{MW}$
$r\mathrm{ACE}_{60}$	4.6	Probability that the absolute value of the one-hour average of ACE exceeds $L_{60} = 20\,\mathrm{MW}$
$r\mathrm{ACE}_{1t}$	0.027	Probability that the one-minute average of ACE is higher/lower than ±100 MW for more than 15 min
$r\mathrm{ACE}_{60t2}$	0.829	Probability that the one-hour average of ACE is higher/lower than ±20 MW within two consecutive hours
$r\mathrm{ACE}_{60t3}$	0.140	Probability that the one-hour average of ACE is higher/lower than ±20 MW within three consecutive hours
$r\mathrm{ACE}_{60t4}$	0.040	Probability that the one-hour average of ACE is higher/lower than ±20 MW within three consecutive hours

the needs of the AS reserves are expressed in the form of inequalities (65.14)–(65.18) rather than exact recommended values for each AS category

$$\mathrm{RZSR} \geq \mathrm{RZSR}_{\min} , \tag{65.14}$$

$$\mathrm{RZSR} + \mathrm{RZTR}^{+} \geq \mathrm{RZSR}_{\min} + \mathrm{RZTR}^{+}_{\min} , \tag{65.15}$$

$$\mathrm{RZSR} + \mathrm{RZQS} + \mathrm{RZTR}^{+} \geq \mathrm{RZ}^{+}_{\sum\min} , \tag{65.16}$$

$$\mathrm{RZSR} + \mathrm{RZTR}^{-} \geq \max\left(\mathrm{RZ}^{-}_{\sum\min}, \mathrm{RZSR}_{\min} + \mathrm{RZTR}^{-}_{\min}\right) , \tag{65.17}$$

where $\mathrm{RZ}^{+}_{\sum\min} \geq 0$, $\mathrm{RZ}^{-}_{\sum\min} \geq 0$ are total minimal volumes of positive and negative reserves, and $\mathrm{RZSR}_{\min} \geq 0$, $\mathrm{RZTR}^{+}_{\min} \geq 0$ and $\mathrm{RZTR}^{-}_{\min} \geq 0$ are the minimal required volumes of the secondary, tertiary positive and tertiary negative reserves, respectively. In addition, (65.18) represents a UCTE $N-1$ criterion

$$\mathrm{RZSR} + \mathrm{RZQS} \geq C_{N-1} , \tag{65.18}$$

where C_{N-1} is the installed power of the largest generator within the control area.

As the energy of the quick-start reserve is limited and due to its quality in terms of a fast response after activation, it should be preserved for future use as much as possible. Thus, it is recommended that this fast service should be replaced by a slower one whenever possible, and the same amount of reserve should be planned for such a slower service. This reasoning is expressed by

$$\mathrm{RZN}_{>30} = \mathrm{RZQS} . \tag{65.19}$$

Figure 65.9 illustrates how the total minimal volumes $\mathrm{RZ}^{+}_{\sum\min} \geq 0$ and $\mathrm{RZ}^{-}_{\sum\min} \geq 0$ are determined from the cumulative distribution function of $\mathrm{ACE}_{\mathrm{OV}}$. According to the reliability standards, the absolute value of the closed-loop ACE is allowed to exceed the threshold 100 MW in $r\mathrm{ACE}_1$% of cases. If this is split symmetrically into positive and negative values, an $\mathrm{ACE}_{\mathrm{OV}}$ that is higher than 100 MW should be compensated by the control reserves except in $r\mathrm{ACE}_1/2$% of cases. Hence, we need at least $\mathrm{RZ}^{+}_{\sum\min} \geq 0$ and $\mathrm{RZ}^{-}_{\sum\min} \geq 0$ reserves to satisfy the standards of reliability derived from area satisfactory performance in the past.

The secondary reserve $\mathrm{RZSR}_{\min}$ should compensate for the fast variations of the open-loop ACE, and the tertiary reserve $\mathrm{RZTR}^{+}_{\min}$, $\mathrm{RZTR}^{-}_{\min}$ should compensate for the slow ACE variations. The minimal needs of these services are determined in a similar manner to the total needs, but by utilizing the cumulative distribution functions of $\mathrm{ACE}_{\mathrm{OV\_slow}}$ and $\mathrm{ACE}_{\mathrm{OV\_fast}}$.

The values of the minimal AS requirements take the form of a time series, which reflects the fact that the behavior of the ACE also varies; it is typically more uncertain during *transition periods* with changeable weather and temperature, such as during spring or fall.

65.2.3 AS Bids from Generation Companies

Before calculating the costs of the optimal AS set, we also need to know what energy and AS bids can be expected on the market (Fig. 65.7). The underlying assumption is that under liberalized market conditions, generation companies are only motivated by economic factors, and their aim is to maximize their profit regardless of transmission system needs and reliability issues. A generation company decides how much of its installed capacity will preferably be offered in the form of energy sold to domestic retailers or abroad and what amount will be offered to the TSO in the form of AS. This part of the model solves a mixed integer linear programming problem involving unit commitment. The main model inputs and outputs are summarized in Table 65.4.

The model does not search for a demand-bid equilibrium on the market, because the computational time associated with a year-ahead simulation would be too high. Hence, the expected AS and energy prices are entered as the inputs. In other words, the model tells the TSO the amount of AS reserves that are expected to be available on the market if their prices are given. Thus, for instance, the TSO can enter the maximum acceptable prices of AS and see whether or not the bids meet the minimal AS needs in such a case.

65.2.4 Procurement of Ancillary Services

The key point is to optimize the AS selection covering the minimal AS needs based on the lowest costs for AS reservation. In the case where the minimal needs of AS in a certain category determined in Step 2 are higher than the offer on the market, the optimal purchase algorithm takes this limited offer into account by substituting the AS with a different AS category if possible. The optimal purchase is stated as a linear optimization problem

$$\min_{\substack{\forall k\\ \mathrm{RZSR}_k\\ \mathrm{RZTR}_k^+\\ \mathrm{RZTR}_k^-\\ \mathrm{RZQS}_k\\ \mathrm{RZN}_{>30k}}} \sum_{\forall k} \Big(C_{\mathrm{RZSR}_k}\mathrm{RZSR}_k + C_{\mathrm{RZTR}_k^+}\mathrm{RZTR}_k^+ + C_{\mathrm{RZTR}_k^-}\mathrm{RZTR}_k^- + C_{\mathrm{RZQS}_k}\mathrm{RZQS}_k + C_{\mathrm{RZN}_{>30k}}\mathrm{RZN}_{>30k}\Big) \tag{65.20}$$

subject to the constraints (65.14)–(65.18). The index k denotes individual AS providers, C_{RZSR_k}, $C_{\mathrm{RZTR}_k^+}$, $C_{\mathrm{RZTR}_k^-}$, C_{RZQS_k}, $C_{\mathrm{RZN}_{>30k}}$ are bid prices of the respective AS, and RZSR_k, RZTR_k^+, RZTR_k^-, RZQS_k, $\mathrm{RZN}_{>30k}$ are the AS volumes purchased from the kth AS provider.

Table 65.4 Main inputs and outputs of the AS market model

Model inputs	
1.	List of power producers acting on the market and portfolio of their generation units
2.	Technical data for generating units (type of technology, minimal and maximal outputs, certified AS ranges, etc.)
3.	Economic characteristics of generating units (variable costs, start-up and shut-down costs)
4.	Planned unit outages
5.	Domestic power consumption and foreign exchange forecast
6.	TSO's expert estimate of future energy and AS prices based on knowledge of the current market situation and possible future trends
Model outputs	
1.	Time series of expected volumes of AS offered by each of the AS providers in the market

65.2.5 Availability of Self-Regulation Power

The transmission system is balanced by not only the TSO but also the area generators. The generation companies are economically motivated to meet their contracted production. Thus, if one or more of their units fail, the remaining capacity of the other units is activated, if possible, to compensate for the forced outage (self-regulation). However, this ability varies in time and depends on instantaneous domestic consumption, foreign exchange, etc. Therefore, an algorithm for computing time-variable available capacity for self-regulation is implemented and conducted as Step 5 in Fig. 65.7. In principle, the remaining available capacity P_{AC} can be determined as

$$P_{\mathrm{AC}} = P_{\mathrm{IC}} - P_{\mathrm{OUT}} - P_{\mathrm{E}} - P_{\mathrm{AS}}\,, \tag{65.21}$$

where P_{IC} is the installed capacity of generation companies, P_{OUT} are planned outages, P_{E} is the sold energy and P_{AS} is sold AS. The self-regulation ability is then taken into account in Monte Carlo simulations where the forced generation unit outages are randomly generated.

65.2.6 Monte Carlo Simulation of Power Balancing

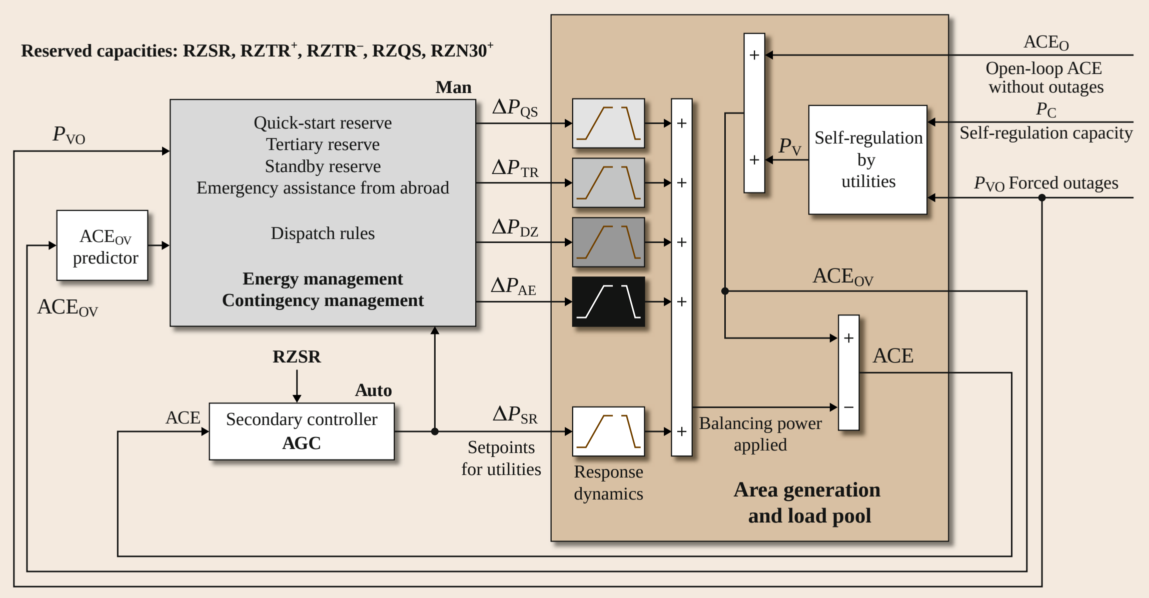
The quality of the transmission system operation must be validated for the intended ancillary services acquired in Step 4 in Fig. 65.7 for several reasons. First, only two of the performance indices $r\mathrm{ACE}_1$ and $r\mathrm{ACE}_{60}$ evaluating the ACE time series were taken into account when calculating technical needs of the AS. Second, purchasing the AS may result in a different composition of AS due to the limited offer from the AS providers. To learn more about the behavior of the transmission system, a power balancing control system simulator is used to simulate the automatic activation of AS and to mimic human operator interventions at the TSO control center [65.19].

The logic used by the TSO operator manually activating the respective categories of AS is modeled as if-then rules. The operator evaluates past and predicted values of ACE, considers the balancing power reserves left for immediate and near-future use and the dynamics of the respective AS (i. e., the delay, ramp up, ramp down), and checks the time taken for the activation or deactivation of the AS to be realized. By means of Monte Carlo simulations, this model generates time series for open-loop ACE [65.19], AS activations/deactivations (both automatic and operator-based) and, consequently, closed-loop ACE during a planning period when using the recommended set of AS. Additional nonguaranteed types of AS, such as emergency assistance from abroad and the purchasing of balancing energy are also used in simulation runs. These types of services are characterized by zero reservation costs and limited availability (i. e., the services might be temporarily unavailable when required by the operator for balance control). The availability of the nonguaranteed types of AS is a parameter that can be set in the simulator.

The master block diagram shown in Fig. 65.10 gives an overall picture of the simulator used in Step 6 in Fig. 65.7. The simulator is directly related to the feedback control scheme from Fig. 65.3.

Simulated ACE_{OV}, ACE with automatic activation of the secondary reserve and manual activation of the tertiary reserve, quick-start and standby reserves, emergency assistance from abroad, and balancing energy from abroad are shown in Fig. 65.11. The simulation shows a record for two days with a large power deviation originating from an outage of a 1000 MW generator. The area control error not compensated by the TSO ACE_{OV} is the curve with the highest magnitude. The producer compensates for the unintended power deviation by activating its own power reserves. As a result, ACE_{OV} tends to be drawn towards zero but the self-regulating action is not efficient enough and so a significant power deviation remains for about 12 h, which is unacceptable.

The situation improves when the TSO activates its reserves. The secondary controller responds to the sudden increase in ACE almost immediately (red). As the secondary power reserve available at that time



ACE_{OV} = Remaining ACE not compensated by the TSO = P_{V}: Forced outages compensated by utilities; ΔP_{EA} = Emergency assistance (from abroad)

Fig. 65.10 Block diagram of a power balancing control system simulation for the area

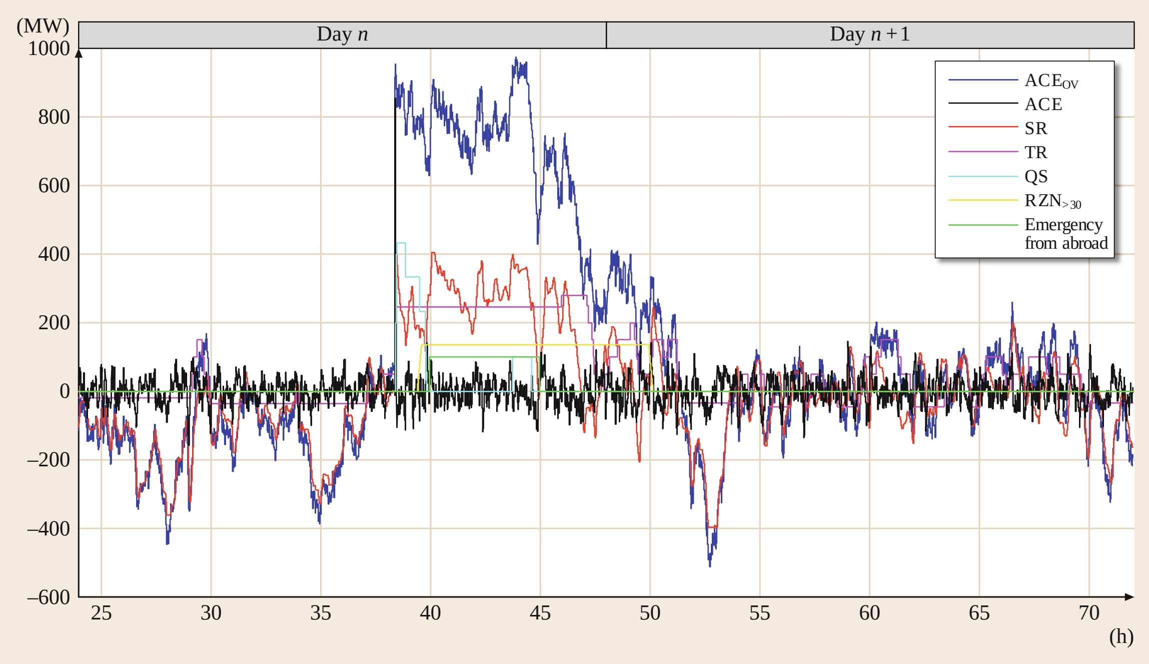


Fig. 65.11 Activation of ancillary services for area power balancing

is about 400 MW, it is not possible to cover the massive outage solely using this reserve, and other services must be called up to assist. The TSO's operator activates the quick-start reserve (cyan) and the tertiary reserve (magenta) at the same time. The pumped-storage quick-start must be saved as its capacity is limited, so the operator tends to replace it as soon as possible with the services with a longer response time, the standby reserve (yellow), and/or tries to acquire services that are not guaranteed: emergency assistance from the adjacent area (green). As a result, the ACE (black) is minimized and the massive outage is well compensated for via a temporary combination of ancillary services, or rather their activation. The TSO's manual intervention also assures that the capacity of the secondary reserve is restored as quickly as possible so the output of the automatic load-frequency controller is driven away from the limits, the power reserve purchased by the TSO in advance.

65.2.7 Control Performance Evaluation

Although the AS needs were determined in Step 2 with the aim of meeting the required reliability in terms of the indices $r\text{ACE}_1$ and $r\text{ACE}_{60}$, not all of the phenomena influencing the reliability could be taken into account in the analytical computations. For instance, the dynamics of AS activation/deactivation and the limited capacity of pumped-storage reservoirs are neglected. Moreover, the AS set recommended for purchase is often different from the minimal set due to limited offers or the substitution of one AS for another. Hence, through the statistical evaluation of the Monte Carlo-simulated ACE, more realistic values of the reliability indices $r\text{ACE}_1$ and $r\text{ACE}_{60}$ can be determined, and the values of the other five indices introduced in Table 65.3 can also be found.

Other performance indices can be evaluated, including NERC's CPS2 and DSC, with the exception of CPS1, as it requires the tie-line frequency deviation to be simulated whereas the simulator [65.17] does not support frequency.

65.2.8 Case Studies

Algorithms of AS planning and the area control system simulator can be used for various studies and analyses supporting TSO's decision-making when planning and purchasing ancillary services.

Technical and economic aspects are closely related in this task, and it is essential to answer the question of how much it will cost to guarantee a commonly agreed and accepted level of reliability in the system services provided by the TSO. The methodology presented here enables the relation between the reliability measured through statistical evaluation of ACE and the cost of purchasing the power reserves to be studied. A typical relation between two reliability indices and the cost of AS is shown in Fig. 65.12.

The plot shows the relative increase or decrease in the AS purchase cost when the request for reliability, measured as the relative number of cases when minute averages and hourly averages of ACE exceed specified levels (e.g., 100 MW for a minute and 20 MW for an hour), is relaxed.

Several studies illustrating the capabilities of the method can be found in [65.16], where the results of year-ahead planning based on specifying the needs for the individual services and the recommended optimal purchase are shown. There can be significant differences between the needs and the purchase, which is due to the fact that RZQS availability is limited to existing pumped-storage plants, and thus influenced by their scheduled outages. A similar rule applies to the standby reserve $\mathrm{RZN}_{>30}$. Thus, more positive reserves must be acquired in the category of faster-response services, according to (65.16). The expert-entered prices of RZSR, RZTR^+ and RZTR^- were related as $C_{\mathrm{RZSR}} > C_{\mathrm{RZTR}^+} + C_{\mathrm{RZTR}^-}$, so the symmetrical RZSR service is preferred to tertiary control, which results in low or even zero purchasing of tertiary reserves RZTR^-. However, the volume of RZTR^+ is higher than the needs during some periods of the year, as it substitutes for the lack of RZQS and $\mathrm{RZN}_{>30}$ in order to reach the minimal positive reserve $\mathrm{RZ}^+_{\sum\mathrm{min}}$. A correlation between greater amounts of faster-response services and improved reliability of power system operations can also be observed.

Self-regulation of power producers is a risky factor. The level to which a generation company is willing to eliminate the difference between the planned and the actual production also depends on the penalty the company will have to pay for the internal error. Studies carried out on the power balancing control system simulator can be used to find out the acceptable relation for internal error charges. Reducing internal power balancing reserves of the power producer will end up increasing the cost of reserves that need to be acquired for the entire area by the TSO. This cost will then be related to the reduction in the producer's balancing power. Simulation studies in [65.16] show that a lack of self-

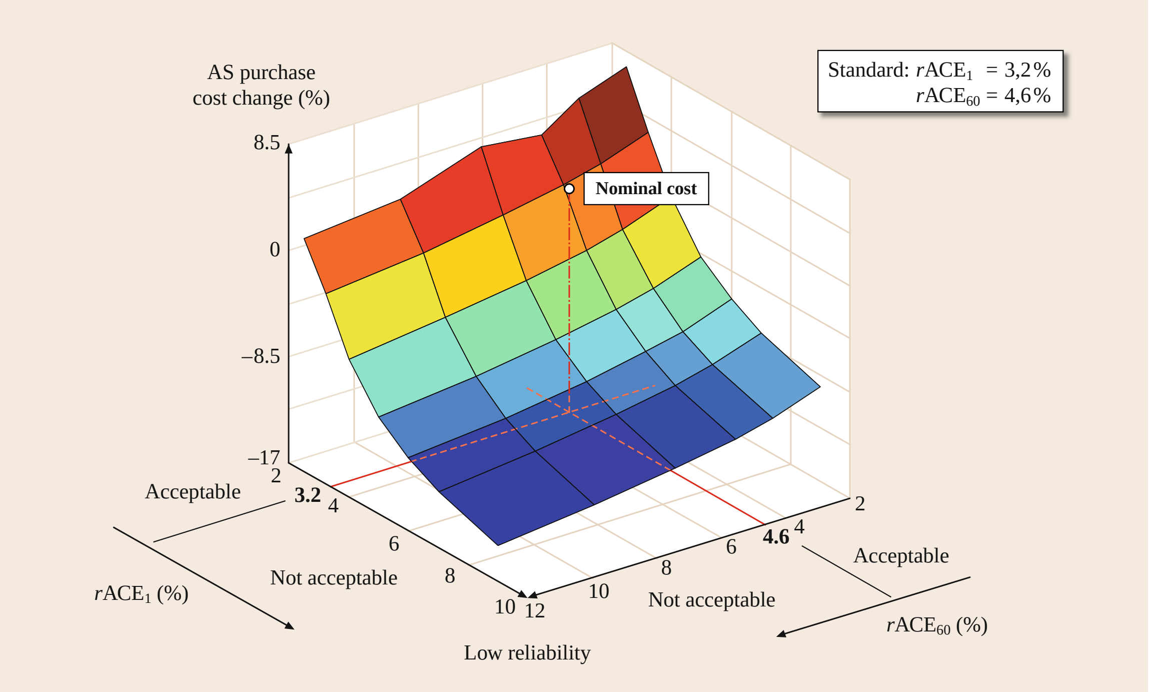

Fig. 65.12 AS costs as a function of required reliability

regulation capability in the utilities could increase the TSO's AS expenses significantly.

The methodology presented deals with the TSO's ancillary services planning and purchasing in order to prevent undesirable situations in the transmission system under changing market conditions and with predicting the influence of these changes on the TSO's expenditure. The AS planning method is shown for year-ahead planning (including various analyses and sensitivity tests, e.g., costs–reliability relation), and the results provide support for the TSO's strategies in the annual AS auction. Despite the fact that the proposed concept is tailored to the needs of a particular control area in the UCTE interconnection, it represents a compact approach to optimal AS planning.

The presented planning and modeling approach is based on historical data. However, the method can incorporate the characteristics of new types of generation units, study what installing wind turbines would mean for ancillary services planning, and evaluate the cost of reaching the same level of reliability.

Price elasticity can be incorporated into the model of energy and AS bids in order to make the entire model more realistic. The costs for AS will then supposedly increase if the (optimal) volumes required in a certain AS category are higher than usual.

The challenging task is to determine the value of unserved energy in the area. The value of unserved energy is the loss to the economy if a MWh of the energy required by consumers cannot be supplied. Consequently, the described methodology allows the optimal balance between the costs of AS and the costs of unserved energy to be found.

65.2.9 Related Topics

Generation from Renewable Resources

Energy sources are undergoing permanent restructuring. Large-scale renewable resource installations like wind power, which is the world's fastest-growing energy technology, represent a new challenge to the power system. The fluctuating nature of wind power affects power system reliability, deviating from the planned power generation, which leads to power balancing problems. Selecting appropriate approaches for calculating the wind power-induced balancing power reserve while respecting the specificity of regulatory and market situations in the region is currently an issue [65.20, 21]. Several detailed technical investigations of the impacts of wind power plants on grid ancillary services needs have recently been performed [65.22]. Although the approaches vary, three utility timeframes appear to be the most significant issues: regulation, load following and unit commitment. This article describes and compares the analytic frameworks from recent analysis and discusses the implications and cost estimates of wind integration. The findings of these studies indicate that relatively large-scale wind generation will have an impact on power system operation and costs, but that these impacts and costs are relatively low at the penetration rates that are expected over the next few years.

Transmission Congestion Management

Grid management has become notably more complex over the past few decades. The level of grid usage is increasing markedly in every region. Consistently high utilization of critical assets in a network often means that these assets become bottlenecks that limit the use of the network and its ability to serve demands at every level consistently and reliably. These points on the grid create transmission constraints. In some cases they create congestion by limiting the buyers' ability to secure energy from the most economical source, meaning that energy must be purchased from closer, more costly generators. In other cases, transmission constraints can cause a reliability problem when customer demands exceed the delivery capabilities of the transmission system plus local generation.

As the power flows over a grid with rapidly changing electrical topologies increase, the local utility is no longer able to see and manage every factor affecting the flows through its share of the transmission grid. The scope of grid monitoring and control that worked effectively in the days of high capacity margins and limited interutility flows are no longer sufficient. Higher grid usage causes greater reliability challenges, and policy-makers and utilities then come to the opinion that increasing the sizes of grid oversight and control organizations is the only effective way of dealing with these challenges.

This problem is of great importance in countries/areas where, besides energy and ancillary services, transmission capacity is a commodity in a deregulated market for electricity and/or where the transmission capacities are almost/temporarily saturated (as is the case when the transmission systems were not designed for the power flows required).

The problems of ancillary services planning and real-time balancing power reserve activation discussed in this chapter do not address one important issue: the limited capacity of the transmission lines. It can happen that the called-up ancillary service will overload a particular transmission line when there is a scheduled energy exchange. As the approach described so far models the control area as a pool, it does not allow the control area network topology to be taken into consideration. Other approaches must be applied.

Reference [65.23] presents major congestion management methods in the new market environment from the international technical literature, which are presented and classified according to security-constrained generation redispatch, zonal/cluster based management, a network sensitivity factor-based method, congestion management using FACTS devices, congestion pricing and market-based methods, congestion management using demand-side resources, and financial transmission rights.

In a restructured power system, the transmission network is the key mechanism for generators to compete in supplying large users and distribution companies. The role of the competitive electricity markets is described in [65.24]. The lessons learned by ERCOT (Texas ISO) in relation to flow-based zonal redispatch to relieve transmission congestion are discussed in [65.25].

Further Reading

The electrical power industry has undergone dramatic changes in many countries in recent years. Recent deregulation has transformed it from a technology-driven industry into one driven by public policy requirements and the open-access market. Now, just as the utility companies must change to ensure their survival, engineers and other professionals in the industry must acquire new skills, adopt new attitudes, and accommodate other disciplines. The book by *Denny* and *Dismukes* [65.26] provides engineers with a broad overview of most of the topics that should be explored in order to understand and meet the challenges of the new competitive environment. Integrating the business and technical aspects of the restructured power industry, it explains how new methods of power systems operation and energy marketing relate to public policy, regulation, economics, and engineering science. The authors examine the technologies and techniques currently in use and lay the groundwork for the coming era of unbundling, open access, power marketing, self-generation, and regional transmission operations.

66. Vehicle and Road Automation

Yuko J. Nakanishi

Presently in the USA, Europe, Japan, and in other parts of the world, intelligent transportation system (ITS) technologies are being developed and deployed to increase the *intelligence* of vehicles. The two key benefits of these technologies are enhancement of safety and mobility of the traveling public. The *intelligence* is provided by electronics, communications systems, software, and human–machine interfaces and is assisting drivers with many aspects of the driving task. Drivers may be warned about potential crashes with other cars, about objects that are hidden from their vantage point, and about excessive speeds. Information about real-time traffic conditions including incidents on a driver's preferred route, travel times to specific destinations, and about restaurants, hotels, and other destination points may be provided. In-vehicle navigation systems can tell drivers how to get to a destination on a turn-by-turn basis and may be linked to a central dispatch center to summon help automatically in case of an accident.

The major initiatives and technologies being developed in the USA – integrated vehicle-based safety systems, forward collision warning systems, road departure crash warning systems, vehicle infrastructure integration – are described and discussed in this chapter. In addition, how they interact with the driver is important in terms of safety, liability, and acceptance of the technologies. The human factors elements that should be considered are presented and discussed in the chapter as well.

66.1 Background

66.1.1 USA – Intelligent Transportation Systems (ITS) Background

In the USA, there were 5 973 000 police-reported motor vehicle traffic accidents in 2006. These crashes resulted in 42 642 deaths and 2 575 000 injuries. During 2006, an average of 117 persons died daily as a result of these crashes. There were another 4 189 000 accidents involving property damage only [66.1]. While the fatality rate has decreased from 1.69 per 100 million vehicle miles of travel (VMT) in 1996 to 1.41 in 2006, these statistics are still staggering and reflect the very serious economic and human costs of these accidents. (National Highway Traffic Safety Administration (NHTSA, http://www.nhtsa.dot.gov/) reports that, in 2000, the economic costs of traffic accidents were US$230.6 billion.)

The latest mobility research by the Texas Transportation Institute concluded that traffic congestion continues to worsen in US cities and causes 4.2 billion hours of delays, depletes US $78 billion from the US economy, and wastes 2.9 billion gallons of fuel. In 2005, congestion in urban areas caused the average peak period traveler to spend an extra 38 h of travel time and consume an additional 26 gallons of fuel, at a cost of US $710 per traveler [66.2].

Intelligent transportation systems (ITS) is the application of electronics, communications, information, and information technology to transportation systems. The primary drivers of these technologies are safety and mobility. Concomitant benefits are efficiency, convenience, and accessibility. Highlights of safety and mobility benefits generated by ITS projects are presented below [66.3].

Safety benefits:

- In Georgia, the Navigator incident management program reduced secondary crashes from an expected 676 to 210 in the 12 months ending April 2004 (2006).
- In North Carolina, a work zone equipped with smart work zone traveler information systems observed fewer crashes compared with other work zones without the technology (2005).
- In Baltimore, a *second train coming* warning system decreased the frequency of the most common risky behavior at crossings (i. e., drivers that crossed the tracks after the protection gates began to ascend from the first train before the protection gates could be redeployed for the second train) by 26% (2002).
- Evaluation indicated that integrating dynamic message signs (DMS) and incident management systems could reduce crashes by 2.8%, and that integrating DMS and arterial traffic control systems could decrease crashes by 2%, in San Antonio, TX (2000).
- In Georgia, call boxes installed on a 39 mile section of I-185 were estimated to eliminate one injury per year, and one fatality every 5 years (2000).
- An advanced curve warning system on an interstate route in northern California caused over 68% of drivers to reduce their speed (2000).
- In a rural area of Virginia, a collision countermeasure system installed on a two-way stop-controlled intersection reduced vehicle speeds by 2.4 mi/h, and increased the average projected time to collision from 2.5 to 3.5 s (2000).
- An automated enforcement systems in California decreased highway–rail grade crossing violations by up to 92% (1999).
- A dynamic truck downhill speed warning system installed on I-70 in Colorado reduced the average speed of passing trucks by approximately 5.2 mi/h (1999).
- In Colorado, a downhill truck speed warning system installed on I-70 reduced runaway ramp usage by 24% and contributed to a 13% drop in crashes involving trucks and excessive speeds (1997).
- After a ramp rollover warning system was installed at three curved exit ramps on the beltway around Washington, DC, there were no accidents at any of these sites during the 3 year postdeployment test period evaluated (1997).
- Following deployment of the TransGuide freeway management system in San Antonio, TX, crash frequency was reduced by 41% and incident response time decreased by 20% (1997).
- Advanced traffic management systems in Amsterdam and Germany reduced crash rates by 20–23% (1999).
- In Japan, a real-time incident detection and warning system installed on a dangerous curve on the Hanshin Expressway decreased the rate of secondary crashes by 50% (1997).

Mobility benefits [66.3]:

- In Georgia, the Navigator incident management program reduced the average incident duration from 67 min to 21 min, saving 7.25 million vehicle-hours of delay over one year (2006).
- In Georgia, the highway emergency response operator (HERO) motorist assistance patrol program and Navigator incident management activities saved more than 187 million US dollars, yielding a benefit-to-cost ratio of 4.4:1 (2006).
- In Utah, incident management teams in Salt Lake Valley area decreased incident duration by approximately 20 min per incident on three major interstates (2004).
- In 2002, the Maryland coordinated highways action response team (CHART) highway incident management program reduced delay by about 30 million vehicle – hours and saved about 5 million gallons of fuel (2003).

- In Albuquerque, NM, work zone surveillance and response at the *Big I* Interchange reduced average clearance time by 44% (2001).
- During the first year of operations at the *Big I* work zone in Albuquerque, temporary traffic management and motorist assistance patrols reduced the average incident response time to less than 8 min, and no fatalities were reported (2001).
- Modeling performed as part of an evaluation of nine ITS implementation projects in San Antonio, TX, indicated that integrating dynamic message signs (DMS), incident management, and arterial traffic control systems could reduce delay by 5.9% (2000).
- The delay reduction benefits of improved incident management in the Greater Houston area saved motorists approximately US $8 440 000 annually (1997).
- In San Antonio, TX, a freeway management system led to an estimated delay savings of 700 vehicle – hours per major incident (1997).
- In Brooklyn, an incident management system on the Gowanus and Prospect Expressways used closed circuit television (CCTV), highway advisory radio, DMS, and a construction information hotline to improve average incident clearance time by about 1 h, a 66% improvement (1997).

The National ITS Architecture [66.4] provides a common framework for the planning defining and implementation of ITS, and defines the required functions, the physical entities or subsystems where these functions reside, and the information flows and data flows linking these functions and physical subsystems together. The National ITS Architecture consists of three layers, institutional, communications, and transportation:

- *Institutional layer*: represents the existing and emerging institutional constraints and arrangements and addresses policy issues, funding incentives, working arrangements, and jurisdictional structure.
- *Communications layer*: comprises communication equipment such as wireless transmitters and receivers.
- *Transportation layer*: presents relationships among the transportation-related elements, including traveler subsystems, vehicles, transportation management centers field devices, and external system interfaces.

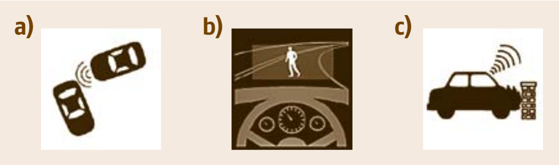

Fig. 66.1 **(a)** Collision avoidance system. **(b)** Driver assistance system. **(c)** Collision notification system

Logical architecture defines ITS processes, process-to-process data flows, and data elements and is not technology specific. Physical architecture is the high-level structure containing major ITS system components. Subsystems are the structural elements of the physical architecture. The subsystems are categorized into center, traveler, field, and vehicles [66.5].

The intelligent vehicles subsystem is comprised of collision avoidance systems, driver assistance systems, and collision notification systems (Fig. 66.1).

Collision avoidance systems (CAS) warn drivers of impending danger. The vehicle warnings need to occur early enough for the driver to take action, and must also be clear and understandable to the driver. Since multiple alarms would be confusing and distracting for the driver, a management system needs to be present to decide which CAS or driver assistance warning to provide when the condition warrants it. CAS systems comprise the following elements:

- *Intersection collision warning* systems detect and warn drivers of approaching traffic at high-speed intersections; these systems use both vehicle- and infrastructure-based technologies. Once vehicle infrastructure integration is in place, other drivers would also be able to receive warnings about impending violations (Fig. 66.2).
- *Obstacle detection* systems use vehicle-mounted sensors to detect obstructions, such as other vehicles, road debris or animals, in a vehicle's path and alert the driver. An example of a more advanced system for obstacle detection and road navigation in intelligent vehicles is presented in Fig. 66.3.
- *Lane-change warning* systems have been deployed to alert bus and truck drivers of vehicles or obstructions in adjacent lanes when the driver prepares to change lanes.
- *Lane departure warning* systems warn drivers that their vehicle is unintentionally drifting out of the lane.
- *Rollover warning* systems notify drivers of heavy trucks when they are traveling too fast for an approaching curve, given their vehicles operating characteristics. This system would also be useful for light trucks (sports utility vehicles (SUVs)) as well.

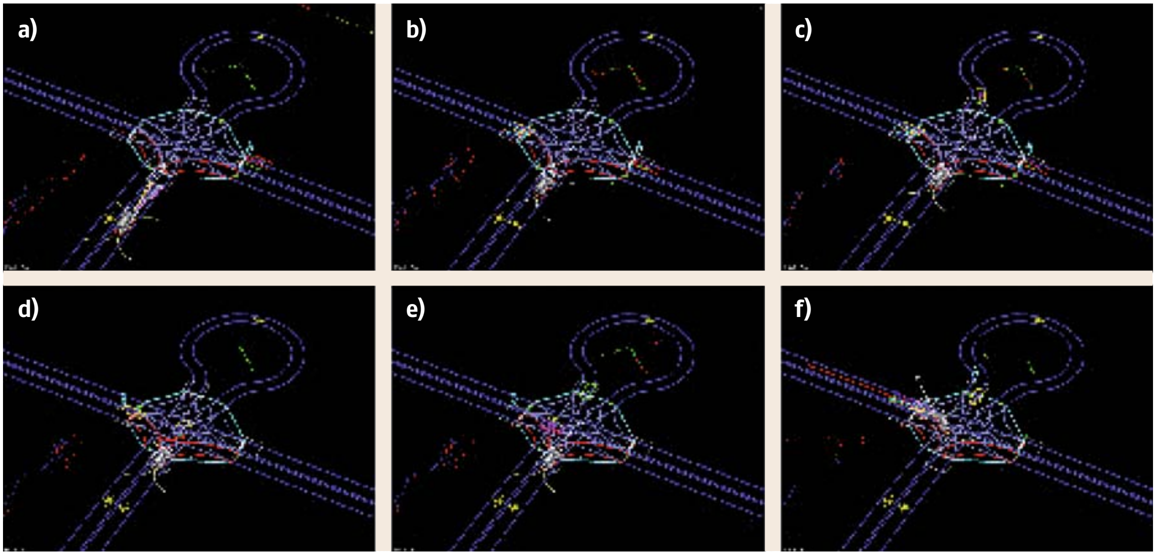

Fig. 66.2 **(a)** The robot approaches an intersection and identifies a waiting car (*rectangle* marked by a *blue diamond*). As the gets closer **(b)** it detects a second vehicle (*rectangle*, *left of frame*), and upon coming to a stop **(c)** tracks a third vehicle, which arrives late (*rectangle middle of frame*). **(d)** The first vehicle begins moving through the intersection, and precedence is transferred to the second vehicle, denoted by the *teal diamond*. **(e)** The second vehicle begins traversing the intersection. **(f)** Upon all clear, the robot takes precedence ahead of the third vehicle and safely navigates the intersection (courtesy of Tartan Racing, Carnegie Mellon University)

- *Road departure warning* systems have been tested using machine vision and other in-vehicle systems to detect and alert drivers of potentially unsafe lane-keeping practices and to keep drowsy drivers from running off the road.
- *Forward collision warning* systems use microwave radar and machine vision technology to help detect and avert crashes. Drivers are warned of unsafe conditions via vehicle displays or audible alerts. If a driver does not properly apply brakes in a critical situation, some systems automatically assume control and apply the brakes in an attempt to avoid a collision.
- *Rear-impact warning* systems use radar detection to prevent accidents. A warning sign is activated on the rear of the vehicle to warn tailgating drivers of impending danger.

Driver assistance systems (DAS) assist drivers navigate their vehicles safely, enhance their vision, and control the speed of their vehicles. These systems will

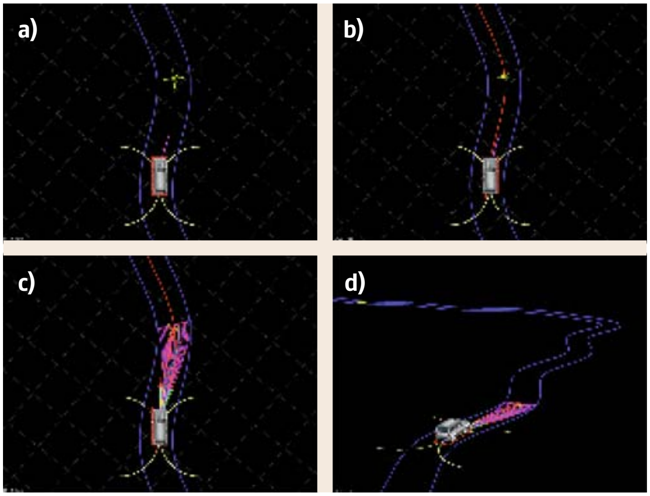

Fig. 66.3 **(a)** Vehicle navigating down a single-lane road (lane boundaries shown in *blue*, current curvature of the vehicle shown in *pink*, minimum turning radius arcs shown in *yellow*). **(b)** extracted centerline of the lane (in *red*). **(c)** candidate trajectories generated by the vehicle given its current state, the centerline path, and lane boundaries. A single trajectory is selected for execution, as discussed. **(d)** the same scenario from an alternative viewing angle (courtesy of Tartan Racing, Carnegie Mellon University)

be especially valuable in inclement weather or in other hazardous conditions. Driver assistance systems comprise:

- *In-vehicle navigation and route guidance* systems with global positioning system (GPS) technology may reduce driver error, increase safety, and save time by improving driver decision in unfamiliar areas.
- *Integrated driver communication* systems enable drivers and dispatchers to coordinate rerouting decisions on-the-fly and can also save time and money, and improve productivity.
- *In-vehicle vision enhancement* improves visibility for driving conditions involving reduced sight distance due to night driving, inadequate lighting, fog, drifting snow or other inclement weather conditions.
- *Object detection* systems warn the driver of an object (front, side or back) that is in the path or adjacent to the path of the vehicle. Currently the most common application is parking aids for passenger vehicles. Toyota's intelligent parking assist (IPA) system uses cameras and sensors to steer the car for the driver for parallel parking or backing into a parking space. Obstacle detection sensors for rear and forward bumpers are available from automakers or available from individual vendors.
- *Adaptive cruise control* systems maintain a driver set speed without a lead vehicle, or a specified following time if there is a lead vehicle and it is traveling slower than the set speed.
- *Intelligent speed control* systems limit maximum vehicle speed via a signal from the infrastructure to an equipped vehicle.
- *Lane keeping assistance* systems can make minor steering corrections if the vehicle detects an imminent lane departure without the use of a turn signal.
- *Roll stability control* systems take corrective action, such as throttle control or braking, when sensors detect that a vehicle is in a potential rollover situation.
- *Drowsy driver warning* alerts drivers when they have become fatigued.
- *Precision docking* systems automate precise positioning of vehicles at loading/unloading areas.
- *Coupling/decoupling*: intelligent cruise control, speed control, guidance/steering, and coupling/decoupling systems which help transit operators link multiple buses or train cars into trains each assist drivers with routine tasks that weight on driver workload.
- *Onboard monitoring* tracks and reports cargo condition, safety, and security, and the mechanical condition of vehicles equipped with in-vehicle diagnostics. This information can be presented to the driver immediately, transmitted off-board, or stored. In case of a crash or near-crash, in-vehicle event data recorders can record vehicle performance data and other input from cameras or sensors.

Collision notification systems (CNS) such as GM's Onstar system report accidents to emergency responders or dispatch centers either manually (MAYDAY) or automatically with automatic collision notification (ACN). Details about the accident such as its severity and number of passengers inside the vehicle may also be reported.

- *MAYDAY/ACN* products utilize location technology, wireless communication, and a third-party response center to notify the closest public safety answering point (PSAP) for emergency response.
- *Advanced ACN* systems use in-vehicle crash sensors, GPS technology, and wireless communications systems to supply public/private call centers with crash location information, and in some cases, the number of injured passengers and the nature of their injuries.

Additional information and ITS initiatives in the USA are provided in subsequent sections of this chapter.

66.1.2 European Union – Telematics Initiatives

In Europe, telematics is the equivalent of ITS technologies, and the key benefits being sought by the European countries are similar. The European Commission seeks to further reduce road fatalities by 50% by 2010. To accomplish this, preventive safety systems are being developed within various Europe-wide initiatives such as eSafety and PReVENT.

The eSafety effort established by the European Commission contains nine working groups which focus on crash-causation analysis, human–machine interface, and others. First-generation or autonomous systems within the vehicle act as isolated units with minimal interaction among the units and minimal external input. The core technologies are:

- Advanced vehicle sensors and communications systems that integrate with onboard navigation systems
- Advanced GPS coordinates with digital mapping and location-based services

- Vehicle and infrastructure information, emphasizing safety and efficiency

Second-generation initiatives such as PReVENT manage the vehicle's performance in the context of the overall system, with the vehicle and infrastructure working together to enhance the safety of motorists [66.6].

PReVENT systems are being designed to be interoperable across European nations and even on a global basis. PReVENT technologies will predict the behavior of traffic and other drivers, and include sensing technologies, in-vehicle digital map and positioning technologies, and wireless communications systems. The technologies revolve around provision of driver-oriented safety applications. A key element of PReVENT is advanced driver assistance systems (ADAS), which was originally initiated as a result of the EUREKA programme for an European traffic of highest efficiency and unprecedented safety (PROMETHEUS) project [66.7].

- The 3 year MAPS&ADAS subproject has produced an ADAS interface, ADAS maps for PReVENT test sites, and a safety impact assessment of the maps. This project is needed because access to map data by applications other than navigation requires a standard nonproprietary interface.
- The ProFusion subproject focuses on sensors and sensor data fusion. The first preliminary concept building phase has been completed. The objectives of the second phase are:
  - To develop concepts and methods for sensor data fusion to improve the reliability and robustness of perception systems
  - To define and implement a flexible and modular architecture for fusion systems with diverse approaches
  - To establish and maintain the Fusion Forum, which promotes sensor data fusion in driver assistance and active safety systems
- RESPONSE 3 will develop a code of practice for the development and testing of ADAS for European industry and will address the key issues of *reasonable safety* and *duty of care* by defining *safe* ADAS development and testing.
- PReVAL subproject will provide PReVENT with a common evaluation framework and methodology to assess the impact of various applications.
- INSAFES (integrated safety system) is developing new control functions to improve the functionality of applications already developed.
- The 3 year WILLWARN (wireless local danger warning) subproject will generate a safety application that warns the driver whenever a safety-related critical situation occurs beyond the driver's field of view. The application will include the development of onboard hazard detection, in-car warning management, and decentralized warning distribution by vehicle-to-vehicle communication on a road network
- The SASPENCE (safe speed and distance) system will guide the driver regarding desirable speed and headway for the given driving conditions.

66.1.3 Japan – ITS Initiatives

In Japan, the focus of ITS efforts has initially been on in-vehicle information systems, and the benefits sought have been in terms of safety and the environment. As in Europe, there has been strong national leadership with regards to achieving these benefits. In comparison with other nations, Japan has many vendors of ITS-related products and services.

The vehicle information and communication system (VICS) is a real-time system that provides information including weather, road and traffic conditions, and navigation assistance to in-vehicle navigation systems. The system has been considered a great success with more than 9 million subscribers in 2004. While the VICS service is free, users pay a one-time setup fee, and purchase the onboard navigation system. This system serves as a catalyst for further ITS deployment in automobiles. Taxi probes equipped with GPS and wiper sensors are used by the Japan Road Traffic Information Center to obtain information about the transportation system; the information is then analyzed and passed along to motorists using VICS. A mobile radio local-area network in the 2.4 GHz bandwidth was installed by the Japan Highway Public Corporation and is used to communicate both data and images to in-vehicle navigation systems [66.6].

Other technologies that have been developed include the following:

- Vehicles equipped with cameras to allow drivers to see objects and roadway features in blind spots. This technology is an element of advanced cruise-assisted highway systems (AHS), which provide information on highway features (curve data or other roadway information) as well as warnings of obstacles. AHS warns drivers of impending dangers and allows a timely response to them.

- The radar cruise control (with low-speed following mode) system enables drivers to adjust headway between their own vehicle and the one immediately ahead, thereby providing uniform traffic flow and automatic adjustment of speed based on the actions of the lead vehicle. Adaptive cruise control provides the added benefit of mild to increasingly intense braking if the driver of a vehicle does not respond safely to a slowing or stopping vehicle ahead.

The remainder of the chapter will discuss specific ITS initiatives established in the USA.

66.2 Integrated Vehicle-Based Safety Systems (IVBSS)

The Integrated Vehicle-Based Safety Systems (IVBSS) initiative addresses the subset of accidents caused by rear-ending, road departures, and lane changes. The initiative involves the development of objective tests and criteria for performance of IVBSS, and how best to communicate an integrated warning to the driver. IVBSS is expected to have the potential to reduce these accidents by almost 50%, which translates into about 21 000 lives saved per year.

The IVBSS program will evaluate the safety benefits and driver acceptance of the following crash warning subsystems [66.8]:

- *Forward crash warning*, which warns light vehicle and heavy truck drivers of the potential for a rear-end crash with another vehicle
- *Lateral drift warning*, which warns light vehicle and heavy truck drivers that they may be drifting inadvertently from their lane or departing the roadway
- *Lane-change/merge warning*, which warns light vehicle and heavy truck drivers of possible unsafe lateral maneuvers based on adjacent or approaching vehicles in adjacent lanes, and includes full-time side object presence indicators
- *Curve-speed warning*, which warns light vehicle and heavy truck drivers they may be driving too quickly into an upcoming curve

The two main functions of IVBSS are *situation characterization*, which determines that a potential crash threat exists, and *threat assessment*, which determines whether an alert should be issued for each warning subsystem. The major elements of IVBSS are as follows [66.8].

- *Sensing subject vehicle information and driver control inputs*: The IVBSS system must obtain certain information from the vehicle; for example, for rear-end crashes, vehicle speed, yaw rate, and driver brake switch are important.
- *Sensing roadway geometry and characteristics*: Obtaining information about the roadway (e.g., road curvature, vehicle axes relative to the lane, position of the vehicle in the lane, determination of whether the lane edges are road edges, time rate of change of the lateral position of the vehicle relative to the road edge).
- *Sensing objects and characterizing object type and motion*: To avoid crashes, identification and location of other vehicles in the same lane and in adjacent lanes are important.
- *Estimating road condition parameters*: Each warning function is required to obtain and use available data that may indicate low road friction.
- *Sensing driver attributes*: In the subsequent year of the research, individual driver behavior will be integrated into decisions about the issuance of crash alerts.

US Department of Transport (DOT)-sponsored efforts have produced driver–vehicle interfaces including visual and auditory display requirements; specific warning messages have been identified and are under development; human factors tests were conducted to test the interfaces and the system itself; and prototype hardware was developed for the IVBSS evaluation.

US DOT-sponsored field tests of forward crash warning (FCW) systems for light vehicles in the Collision Avoidance Metrics Partnership (CAMP) program which produced performance criteria for radar-based FCW crash warning systems [66.9]. Further FCW crash warning systems research was performed in the Automotive Collision Avoidance Systems (ACAS) program [66.10–12].

66.2.1 IVBSS Systems Architecture

The systems architecture diagram shown in Fig. 66.4 displays the major subsystems along with the sensors and software, and the hardware interfaces and communication protocols of the IVBSS.

The five major elements of the architecture (to the left of the buses) are:

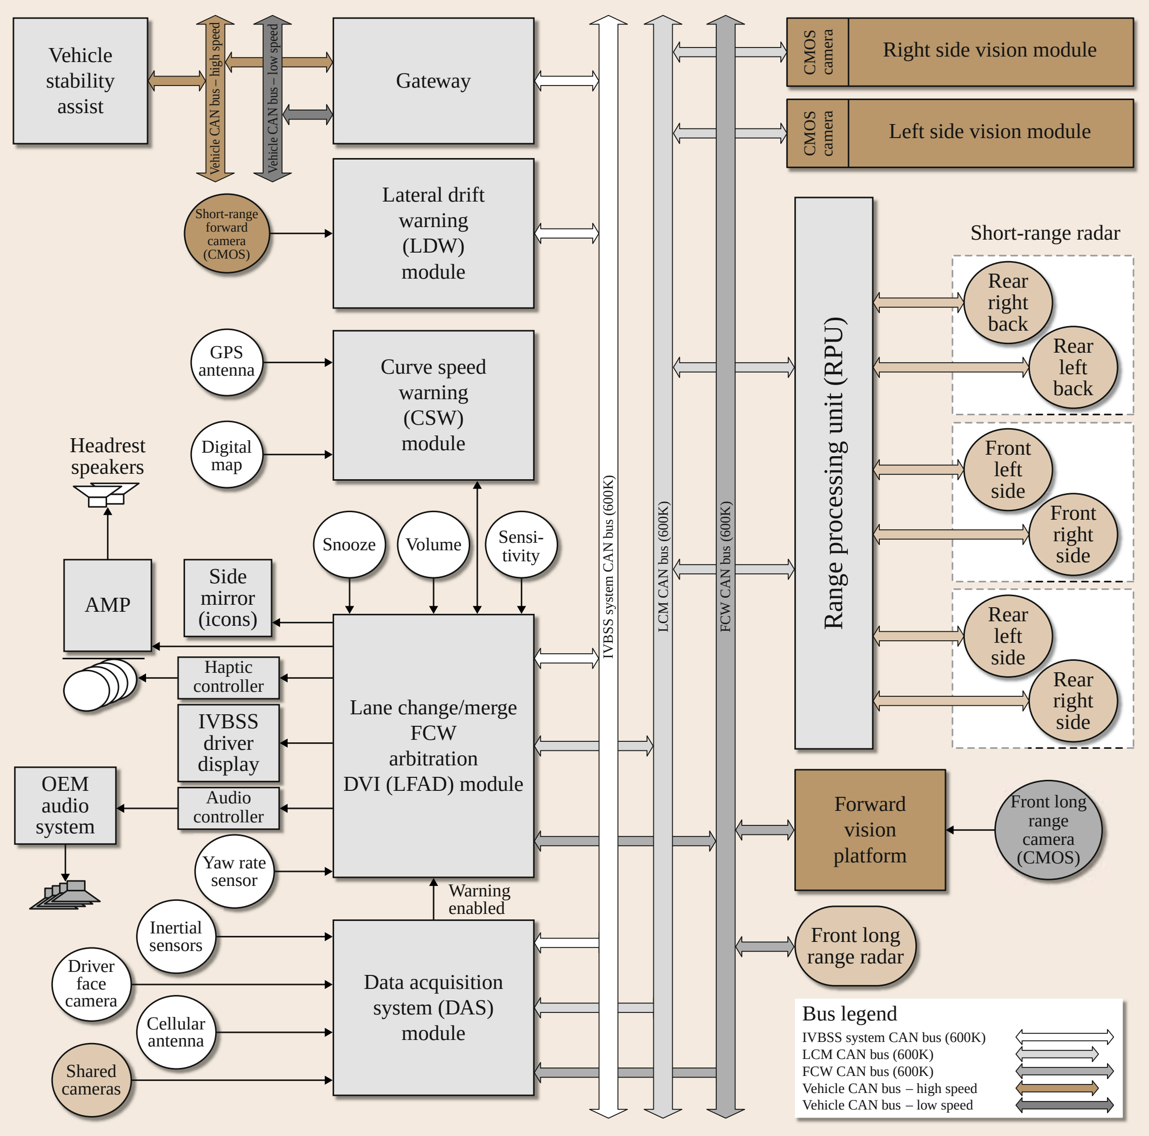

Fig. 66.4 IVBSS system architecture (after [66.8])

- *Gateway*: Translates appropriate messages from two original equipment manufacturer (OEM) data buses to one of the project CAN buses
- *Lateral drift warning module*: Uses forward vision-based lane tracking and other signals from the CAN bus to broadcast LDW (lane departure warning) alert requests onto the bus
- *Curve speed warning module*: Uses GPS, an on-board digital map, and other information to broadcast CSW alert requests onto a serial link to the LFAD (light-vehicle module for LCM, FCW, arbitration, and DVI) module
- *LCM (lane change/merge warning)/FCW/arbitration/DVI (driver-vehicle interface) module*: A chassis that includes processors and other hardware on which LCM, FCW, arbitration, and DVI are hosted
- *Data-acquisition system module*: A two-central processing unit (CPU) module with peripherals that records data.

The additional elements above the three IVBSS CAN buses include two vision-based modules that assist with LCM functionality on the left and right side of the vehicle and a third vision-based module that assists FCW target selection and three pairs of short-range radars communicating with the IVBSS CAN buses through a radar processing unit (RPU).

66.2.2 Forward Collision Warning (FCW) System

Forward collision warning (FCW) systems warn the driver when the vehicle is about to crash into the rear-end of another vehicle or object. FCW systems use sensors such as radar, GPS, and vehicle-to-vehicle communications systems in combination with appropriate algorithms to detect static and moving obstacles and determine when to issue an alert request. The request is forwarded to an arbitration subsystem which receives requests from all driver warning systems and decides which warning to issue. The two important driver behavior parameters are: driver brake reaction time – the time required for the driver to respond to the alert by braking – and driver deceleration behavior in response to the alert under a wide range of conditions [66.9].

Figure 66.5 depicts a cooperative FCW application.

The host vehicle, equipped with the FCW system, can transmit and receive dedicated short range communications (DSRC) messages while only target vehicle 2 has a similar DSRC messaging system. The host vehicle's system will scan vehicles in its sensing area, choose the closest in-path target, and analyze the target's dynamics information. If the target is a threat, a warning will be sent to the driver of the target vehicle. Currently, FCW updates at 100 ms and have coverage ranges of 150 m.

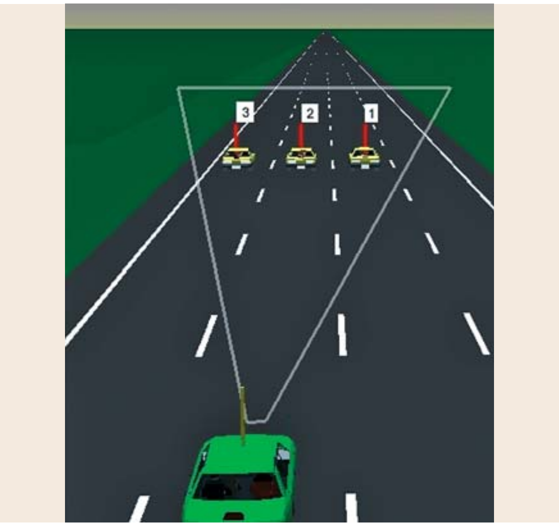

Fig. 66.5 Cooperative forward collision warning application (www.nhtsa.gov)

The system performance is enhanced by vehicles that have DSRC due to the additional redundancy provided in vehicle detection. Redundancy is important especially in adverse environmental (e.g., snow) conditions. Dynamics information received from the target vehicle is richer; information about vehicle size, type, position, and turn-signal status can be transmitted to the host vehicle. Also, the information is received with low latency. Earlier detection of the target vehicle cutting into the host vehicle's path is possible due to information about turn-signal status, steering wheel position, and yaw rate. Conversely, false alarms may be reduced by earlier detection of the target vehicle leaving the host vehicle's path.

Another benefit of DSRC-equipped vehicles is early detection of stopped vehicles. Presently, it is not possible to identify stopped vehicles until it is too late to issue a warning to prevent an accident. A DSRC-equipped vehicle can warn other vehicles that it is stopped. Once all vehicles on the road are equipped with DSRC, sensors would not be needed.

A Forward Collision Warning Requirements Project sponsored by NHSTA sought to develop a FCW crash alert timing approach by examining *last-second* braking and lane-change maneuvers. One finding was that differences in last-second braking and steering were dependent on kinematic conditions.

Two braking onset models were developed – one using linear regression, and the other using logistic regression.

1. The first model develops a deceleration value above which the driver is assumed to be in alert mode when the driver is about to brake. The inputs of the model were the closing speed between the following and leading vehicle, the lead vehicle deceleration value, and knowledge of whether or not the lead vehicle is moving or stationary.
2. The second model is the *three-tiered inverse time-to-collision* model which predicts the probability that a driver is in an appropriate alert condition. The model contains inverse time to collision which is the difference in speeds of the following and leading vehicles divided by the ranges between the vehicles.

The FCW software modules are as follows:

1. *Radar-based scene tracking*: Tracks objects with respect to the subject vehicle
2. *Path prediction and data fusion*: Determines the upcoming geometry
3. *Primary target determination*: Determines the in-lane primary target that is considered the most likely to pose a crash threat
4. *Vision-based primary target validation and characterization*: Validates the choice of primary target, and includes verification that the target is a relevant vehicle
5. *Threat assessment*: Given the primary target, decides whether to issue an FCW crash alert request
6. *FCW false-alarm management*: Manages false alarms to reduce the nuisance alarm rate using historical data and subsequent driver responses

66.2.3 Road Departure Crash Warning (RDCW) System

Road departure accidents make up less than one-fifth of accidents but cause almost 40% of annual highway fatalities and are often caused by driver inattention, intoxication or drowsiness. Road departure crash warning (RDCW) systems warn drivers of impending road departure crashes due to lateral drift (unintentionally moving into another lane) or excessive curve speeds.

The Intelligent Vehicle Initiative (IVI) Road Departure Crash Warning System Field Operational Test (RDCW FOT) project conducted under a cooperative agreement between the US Department of Transportation and the University of Michigan Transportation Research Institute and its partners provided valuable insights into driver behavior and the specific benefits of the RDCW system which may be generalized to similar systems. The RDCW system tested in the RDCW FOT project targeted lane departure crashes as well as vehicles traveling into curves at unsafe speeds [66.13].

The RDCW system architecture developed for the project is shown in Fig. 66.6.

The *lateral drift warning system* (LDW) provided a set of driver alerts in the form of visual and haptic seat vibrations when the vehicle started to drift towards or outside of the lane boundaries; the driver was then expected to assess the situations and take appropriate action. The LDW system issued imminent alerts in the form of a visual icon and audible message in more hazardous conditions (e.g., when striking an object was imminent).

The key primary sensors used by the LDW system were forward cameras to identify the lane boundaries and road edges, brake switch, and turn-signal switch. Supporting equipment were GPS, a digital map and database, vehicle speed, yaw-rate gyro, and forward- and side-looking radars.

The three major changes effected by the LDW system on driver behavior were all positive; these changes were:

1. The rate of turn-signal use during lane changes increased.
2. Lane keeping performance improved: The standard deviation of lane position decreased significantly: the number of events in which the outside of the vehicle's tire crossed the lane edge or came within 4 inches of the lane edge was reduced by 50%. The time spent within 4 inch of the lane edge or outside the lane edge was reduced by 63%.
3. With the warning system in place, the data suggest that the vehicle returns to the lane more quickly.

The *curve speed warning system* (CSW) warns drivers to reduce speed before entering an upcoming curve. The CSW system uses GPS and a digital map to determine curve locations and radii. Recent driver actions such as applying turn signals were incorporated into the system's decision to issue an alert. The driver warnings consisted of visual, audible, and haptic cues similar to those of the LDW system.

In addition to GPS and a digital map, the CSW system used vehicle speed and yaw-rate gyro as the primary sensors, while the supporting equipment consisted of the camera, brake switch, and turn-signal switch.

66.2.4 Human Factors

Background

Human factors research is an important aspect of vehicle automation systems. Evaluation of driver interaction with driver assistance systems such as in-vehicle navigation systems, evaluation of different user interfaces for the systems, and driver understanding of and reaction times to collision warning systems are essential in the development of a safe and effective technology. According to NHTSA, driver distraction contributes to 20–30% of crashes, and in-vehicle navigation systems and other systems that require driver attention will cause driver distraction. A 2000 NHTSA study confirmed that entering destinations into navigation systems along with cellphone dialing and radio tuning were distracting to the driver [66.14].

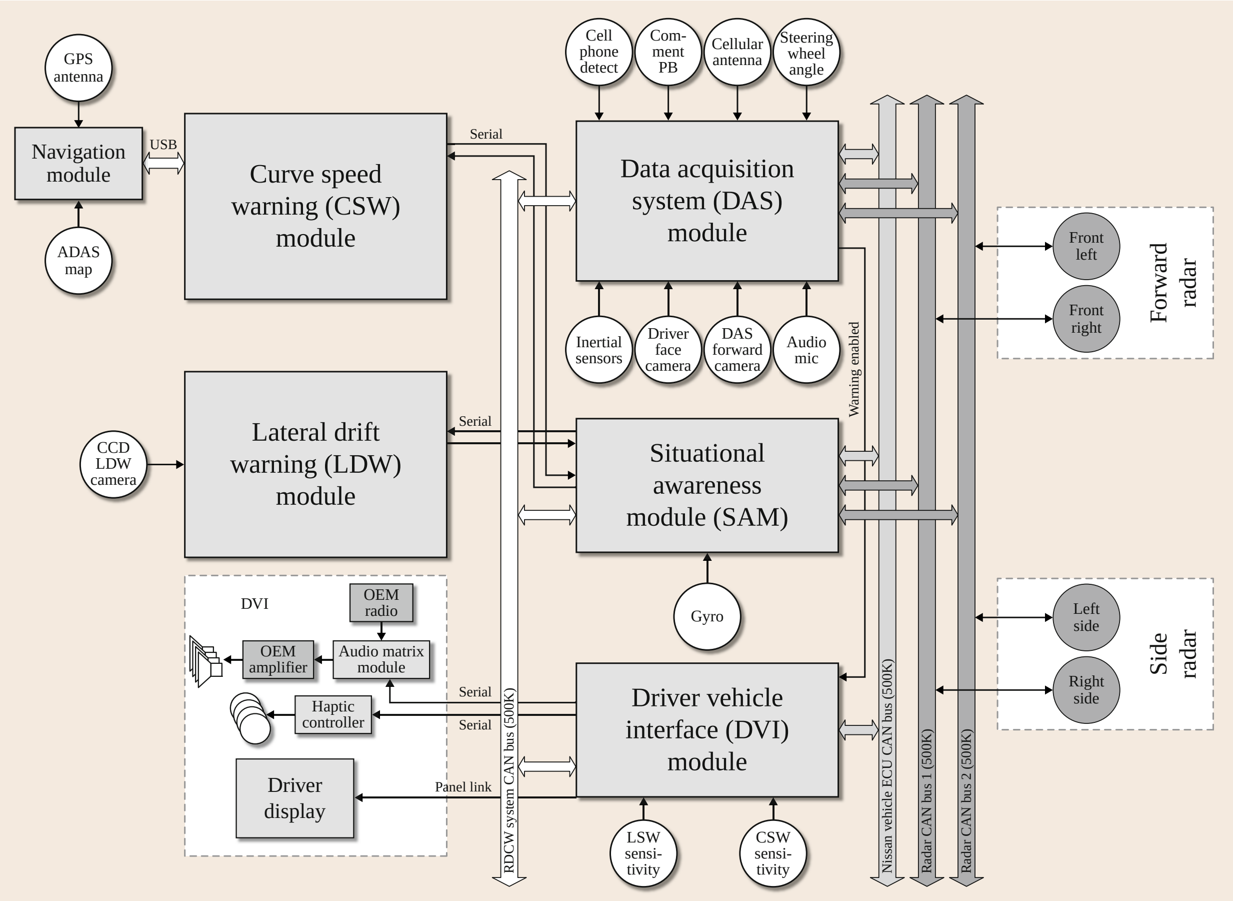

Fig. 66.6 RDCW system architecture (after [66.15]) (PB – push button)

Understanding driver behavior is also important in minimizing nuisance or false alerts, which not only cause stress and irritation to the driver but may also cause driver distraction. For instance intentional lane changes involve particular actions by the driver which may resemble actions taken when an accident is imminent. Therefore precisely differentiating driver behaviors is necessary.

How is human factors research conducted? Vehicle simulators used by NHTSA, car manufacturers, research centers, and driver training centers are valuable in the initial research and development (R&D) of vehicle technologies. In the continuum of assessment methodologies, simulators offer the greatest range of possible scenarios and driving conditions within a safe setting and are at the lowest end in terms of noncapital resource expenditures. Modular design simulators have interchangeable cabs which can be configured for different vehicle models. Multistation driving simulator allows one controller/instructor to control multiple driving stations, enabling simultaneous multiple simulation runs. Recently Toyota introduced its new simulator that imitates speed, acceleration, deceleration, comfort conditions, and conditions at intersections. The simulator is comprised of eight high-precision projectors within a large dome which has a turntable, tilt mechanism, and vibration equipment. The dome is on a track that allows forward, backward, and side-to-side movement. Jaguar and Land Rover's engineering facility in the UK also introduced a state-of-the-art simulator that relies more on virtual reality to create three-dimensional (3-D) vehicle exteriors and interiors [66.16]. Less sophisticated simulators might consist of a steering wheel connected to a monitor displaying roadway images.

A proving ground is the next step in the development and testing process. Before systems are tested on the road, it is prudent to test them in a more controlled environment. Most automakers have their own proving ground or use an independent facility. These facilities, like simulators, range in size and number of features. Some facilities may have 50 miles of roadway of varying types. After the system has undergone additional modifications and fine-tuning, realistic driving scenarios should be evaluated.

Field testing on actual roadways is resource intensive because multiple vehicles need to be fitted out with the technologies and then test subjects recruited to drive the vehicles for a certain number of weeks. Usually baseline data without the use of assistance or warning systems to reveal a driver's natural driving behavior are gathered initially and then compared against their behavior after the systems are turned on.

To be able to generalize test results in field tests, a sufficient number of test subjects should be selected from a diverse population in terms of age, gender, and driving experience; testing should be conducted under a variety of weather and traffic conditions, different roadway geometry, and freeway and local roadways in urban, suburban, and rural settings; and, optimally, it should be performed in real-world settings.

66.3 Vehicle Infrastructure Integration (VII)

In order to connect drivers, roads, and vehicles, the US Vehicle Infrastructure Integration or VII has been established. VII is envisioned to be a national communications infrastructure and will enable vehicle-to-vehicle and vehicle-to-roadside communications. The dedicated short-range communications (DSRC) 5.9 GHz system, a reliable short-range wireless technology, has been designated for transportation and public safety applications. What will be required will be the development of national standards for interoperability, close collaboration among US DOT, state DOTs, and vehicle makers, the development of key technologies, and the resolution of political, institutional, legal, economic, and social issues connected with the infrastructure.

The four phases of the VII initiative are [66.17]:

1. Case and application development planning
2. Proof-of-concept testing
3. Prototype development, testing, and analysis. Human factor issues will be addressed, real-world applications refined and expanded, and institutional challenges considered, such as citizen anonymity, privacy, and security.
4. The final step is deployment readiness and support, including identifying the resources, policies, and governance necessary to move forward.

Phase 1 has been completed, and phase 2 testing is now underway, with California and Michigan having the most VII test-bed infrastructure. Also, a large demonstration of VII is planned in New York City in November of 2008 at the 2008 World Congress and ITS America 2008 annual meeting.

66.3.1 VII Benefits

VII safety benefits are brought about by collision warning systems on highways and local arterials, intersection collision avoidance technology, traffic violation warnings, and roadway curve warning; for example a broken-down vehicle on an interstate could send wireless messages to an approaching semitrailer truck, and on to the cars behind it. According to Bob Lange, executive director of vehicle structure and safety integration at General Motors Corp, it could even apply the car's brakes automatically if the driver behind the truck is distracted. If there is a potential conflict at an intersection, the roadside infrastructure could transmit appropriate messages to the vehicles approaching the intersection, and the vehicles would then alert the drivers. Similarly, warnings would be issued if another car is in a vehicle's blind spot, or if a lane change is required due to construction work.

Other benefits enhance the mobility of drivers and their access to desired destinations. In-vehicle navigation systems direct drivers by voice to their destinations and provide convenient real-time turn-by-turn directions. Some systems have voice recognition capability so that the driver need not manually input the destination, and other systems assist drivers optimize their trips and can incorporate personal preferences such as avoiding highways. In-vehicle information systems assist drivers find destinations such as hotels, restaurants, and gas stations, and may even have real-time information comparing gas prices at different stations. These systems can also help drivers avoid congested roads by providing real-time incident and delay information.

Vehicles, acting as information probes, would collect and transmit data about traffic and road conditions anonymously to the roadside infrastructure, which would then process the information and send it out to the vehicles on the road; users of the data could be charged a subscription fee, making VII a viable business opportunity for the private sector. This information can also be used by transportation planners and traffic management center (TMC) operators for corridor management tasks.

66.3.2 VII Risks

Historically the majority of potential technology users will only adopt once the very early users, who are willing to experiment, try and approve a new technology; cellphones, for instance, took 20 years before achieving widespread consumer acceptance [66.18]. The VII infrastructure will take a large amount of resources to deploy, about US $6–8 billion, which will likely require Congressional approval or a combination of government and private-sector involvement.

The primary risks for VII are the following technical and market risks.

Technical risks include: the need to integrate multiple technologies; ensuring connectivity within the DSRC network, and a determination of how to handle the data generated by the system; the development of a technology that will be able to perform real-time analysis of data from many different input sources. There is also a question over whether the technologies will be effective if only a portion of users adopt them. Also, how the entire country will be mapped, and how VII can be flexibly applied to local needs, will need to be determined.

Market risks include the identification of funding for the system, user acceptance and willingness-to-pay issues, and difficulty in accurately assessing system value until after the system has been implemented. From the automakers' perspective, the introduction of new features and innovations is always risky, particularly a safety feature which could increase the likelihood of lawsuits. Therefore the business case for automakers to incorporate these systems into their vehicles must be especially strong.

Because of the uncertainty with regards to which technologies in which form will receive the greatest user acceptance, an open architecture would be recommended. Also, the development and use of industry standards will be important. Industry standards such as local interconnect network and media-oriented systems transport are being created for communication buses to link electronic control units, subsystems, and sensors. Automotive open system architecture (AUTOSAR), a partnership of auto manufacturers, suppliers, and tool developers, is attempting to become the de facto standard-setting organization for the auto industry on a global basis. AUTOSAR seeks to minimize barriers between functional domains and networks independently from the hardware and to manage the increasing complexity of the technology. AUTOSAR is an open and standardized global automotive software architecture with the following motto: *Cooperate on standards, compete on implementation* [66.19].

66.4 Conclusion and Emerging Trends

While fully automated driverless vehicles and flying cars are many years away, ITS technologies have been increasing the capabilities, intelligence, and safety of the automobile. An early generation of such vehicles can be seen in Figs. 66.7 and 66.8. The percentage of total vehicle value accounted for by electronics and software is currently 15% for compact cars, 28% for luxury cars, and 47% for hybrid cars, and is expected to rise yearly. The continuing need for mobility and

Fig. 66.7 Defense Advanced Research Projects Agency (DARPA) car at the Intelligent Vehicle Conference 2008, Eindhoven

safety enhancements will ensure the growth of the value of electronics and software; the increase is estimated to be about 150%, from US $187 billion in 2002 to US $464 billion in 2015 [66.20].

Much progress has already been made in deploying individual ITS technologies, and many mobility and safety benefits are already being experienced. The National ITS Architecture has been the unifying framework allowing the disparate transportation technologies to work together; and vehicle infrastructure integration will be the engine by which vehicle-to-vehicle and vehicle-to-roadside communications will take place. Once the Integrated Vehicle-Based Safety Systems initiative is completed and the safety-oriented ITS technologies are implemented, even more safety benefits are expected to be realized.

67. Air Transportation System Automation

Satish C. Mohleji, Dean F. Lamiano, Sebastian V. Massimini

The air transportation system infrastructure is comprised of communication, navigation, surveillance, and air traffic management systems, and is known as the National Airspace System. This chapter describes the current very high-frequency and high-frequency modes of communication, very high-frequency omnidirectional range, distance measuring equipment, and instrument landing systems for navigation/guidance to the aircraft, and primary, as well as secondary radars, for surveillance. The two primary functions of the ground-based air traffic management system, viz. traffic flow management for strategic air traffic planning and air traffic control for safe movement of aircraft, are discussed in detail. This chapter also addresses the limited role of automation in both the aircraft cockpit and the ground-based air traffic management system.

The US civil air transportation system today handles over 700 million passengers and 40 billion revenue ton miles of cargo annually that require about 23 million aircraft operations. Each aircraft operation represents a flight from take off to touch down between its departure and destination airports. This number is forecasted to reach a level of 35 million operations by the year 2025. Although the air transportation system has recorded a very high level of safety over the years, the continued growth in demand for air traffic services has created operational inefficiencies, which result in significant flight delays and lost revenue for the users. Today, a majority of decisions in the aircraft and in the ground control system are manual. The human decision making is intensive for the pilots and controllers in terms of their workloads, and will become unmanageable as traffic levels grow. In order to deal with the traffic growth, the future air transportation system will require increased automation of air/ground functions to enhance safety, capacity, and flight efficiency while reducing delays and workload.

The performance of the air transportation system is measured by four key metrics relating to safety, capacity, flight efficiency/delays, and workload. Because aircraft safety is of the utmost importance, the US Government has established regulations that require the aircraft to maintain a minimum separation distance from other aircraft. These separation minima vary with the phases of flight. Explanations of the separation minima and their influence, as well as limitations on flight operations, are provided. How the use of automation could in the future overcome these limitations is also discussed.

Efforts are underway to define concepts for the next-generation (NextGen) air transportation system in the USA, and the Single European Sky air traffic management (ATM) research project in Europe. The Joint Planning and Development Office, mandated by the US Congress, is charted to develop NextGen concepts for the years 2025 and beyond. The goals and requirements of the NextGen system are presented. Also discussed is the ongoing research and development of new satellite technologies, including data link and satellite-based navigation and surveillance, as well as the needed automation of ground-based decision support functions. It is expected that enhanced automation in the aircraft and in the ground system will provide safe and efficient services to a significantly higher number of aircraft operations in the future.

The civil air transportation system is an essential component of the global economy. It is required for timely movement of people and cargo. Until now, air travel has been the safest mode of transportation per passenger mile. Because of the cost, air transportation has not been the primary mode of transportation for long-distance travel in most countries, even though it has been widely used in the USA. However, the demand for air travel around the world is now increasing at a fast pace to meet multinational commerce needs. For globally harmonized aircraft operations, the International Civil Aviation Organization (ICAO), in collaboration with National Civil Aviation Authorities (CAA), has established standards and operating procedures to be followed by all aircraft operators and air traffic service providers.

In the US, the National Airspace System (NAS) is a complex system of human-centric systems providing communication, navigation, and surveillance (CNS), and air traffic management (ATM) services to aircraft flying passengers and cargo. During 2006, over 700 million passengers used NAS, and the demand for air travel is expected to increase beyond one billion passengers by the year 2015. The annual cargo revenue ton miles exceeded 40 billion in 2006 [67.1], and is continuing to grow with the significant demand for goods and services.

In order to meet the challenges of greater demand for air travel, it is imperative to have an air transportation system that not only maintains or enhances safety, but also provides efficient flight operations. The current aircraft operations and the air traffic control (ATC) services are primarily manual open loop, where the pilots in the aircraft and controllers on the ground interactively make decisions based on the available information. The safety of the aircraft in the air is provided by adhering to the established distance separation rules or *separation minima* in both the horizontal and vertical domains. Thus, although safety is assured, these separation requirements between aircraft often adversely impact the efficient use of airport and airspace capacity, thereby resulting in flight delays and creating extensive workload for the humans operating the system. With the ever-growing demand for air traffic services, as these capacity resources become scarce, there is a need to develop closed-loop feedback control NAS capabilities that can provide automated decision support to maximize capacity, enhance flight efficiency, and reduce pilot/controller workload by minimizing reliance on cognitive decision making.

This chapter describes the current NAS CNS/ATM infrastructure, and the extent of the role that automation plays in specific aircraft- and ground-based functions for managing and controlling traffic. The limitation of these functions is discussed with their impact on flight safety, airspace/airport capacity, aircraft operational efficiency, and operator workload. The requirements for the future air transportation system are presented, not only to overcome the shortcomings of the current system, but also to meet the service demands of future users effectively. The ongoing application of automated key functions to meet the future system requirements are presented to address hybrid automation/human decision making in the cockpit and on the ground.

The scope of the contents presented here is limited to an understanding of how the automated functions-generated information helps manual decisions today, and how automation will generate most decisions (except those that are safety critical) in the future for strategic planning and tactical operations during all phases of flight. Any consideration of the use of automation in design and control of the aircraft (except for safe navigation and efficient energy management), or a discussion of the US Government programs to upgrade and automate ground systems, is beyond the scope of this chapter.

67.1 Current NAS CNS/ATM Systems Infrastructure

The current NAS infrastructure is comprised of a CNS system architecture, and the ATM system that is dependent upon an integrated system of airports and ATC facilities. The ground-based ATM system includes data/information acquisition and processing as well as display capabilities supporting people in making decisions to manage and control aircraft operations. The CNS architecture deploys:

1. Very high-frequency (VHF) voice/data communication over the continental USA, and high-frequency (HF) communication in the polar region and over the ocean for air/ground communication
2. VHF omnidirectional range (VOR) and distance measuring equipment (DME): ground-based navaids for navigation over pre-established routes, with precision landing guidance to primary airports provided by the instrument landing system (ILS), and nonprecision landing guidance available from VORs and nondirectional beacons (NDB)
3. Surveillance to locate and track the aircraft provided by the primary and secondary surveillance radars (SSR). The weather radars detect and provide weather and wind information in some aircraft cockpits and to the ground system.

The ATM system has two distinct functions: traffic flow management (TFM) and ATC. The TFM function is involved in strategic planning of flight operations across the entire NAS based on the forecasted weather and traffic conditions throughout the airspace and at all major airports. This is to balance the expected demand with the airspace/airport capacity resources in order to maximize operational efficiency and minimize delays. There are, on average, 55 000 daily operations in the NAS. The ATC function provides tactical control

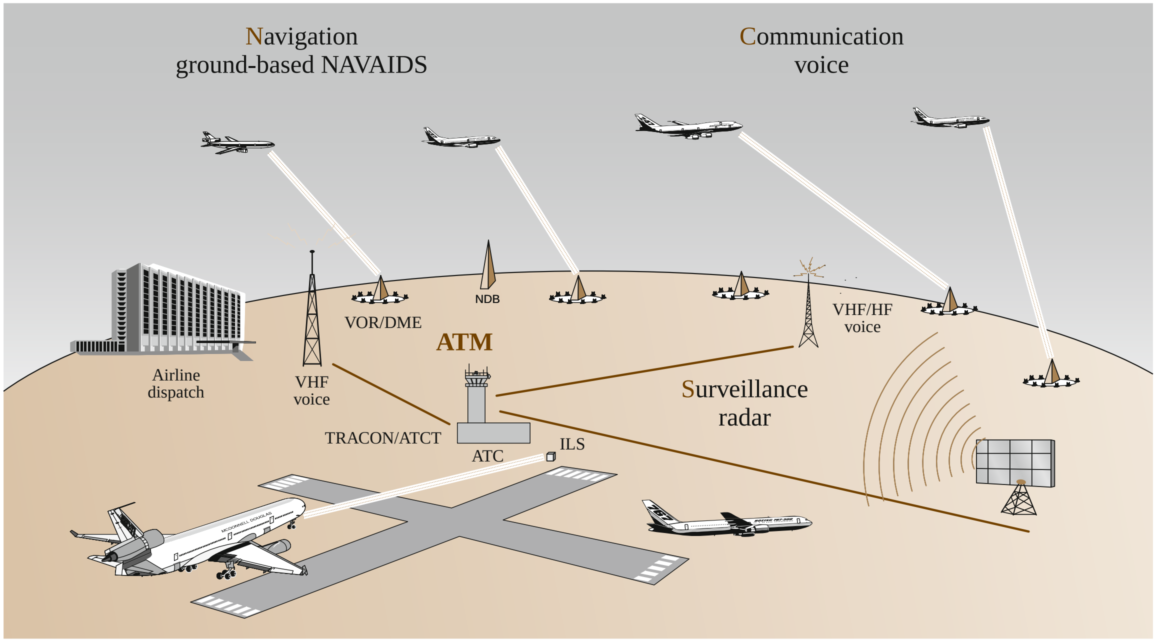

Fig. 67.1 NAS CNS/ATM infrastructure

of airborne aircraft and is designed to help controllers maintain safe separation between aircraft. At an instant of time, the ATC function controls up to 6500 aircraft operations during peak traffic conditions [67.1]. The NAS-wide TFM function is located in the air traffic control system command center (ATCSCC), whereas the regional and local TFM functionality is provided by the traffic management units (TMU) in the 20 air route traffic control centers (ARTCC) and the terminal radar approach control (TRACON) facilities located at the primary airports. The ATC functions for aircraft movements at the airport surface and during departures/arrivals are handled by 400 air traffic control towers (ATCT) located at the airports. The ATC functions to separate aircraft up to about 30 nmi (nautical miles) from the primary airport are provided by 185 TRACONs, and for flights through the rest of the airspace by the ARTCCs. The TFM functions interface with the flight operators through the airline dispatch offices or the airlines operation centers (AOC) and flight service stations (FSS). The ATC functions require direct interaction between the ATC facilities and the aircraft [67.2,3]. Figure 67.1 shows schematically the NAS CNS/ATM infrastructure.

The US Federal Aviation Administration (FAA) has classified the national airspace into six categories in accordance with the ICAO airspace classifications. Airspace classified as class A, B, C, D or E is designated as *controlled* airspace, where ATC services are available, including air/ground communications, navigation aids, and aircraft-to-aircraft separation assurance. Class G airspace is uncontrolled airspace where the ATC system is not responsible for managing traffic.

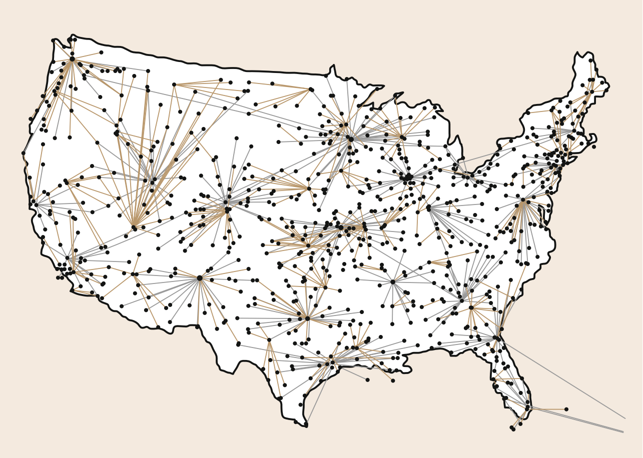

Fig. 67.2 US VHF voice radio network

The following provides details on controlled airspace classifications:

- Class A: Class A airspace covers from 18 000 ft mean sea level (MSL) to 60 000 ft MSL.
- Class B: Class B airspace exists at 29 high-traffic-density airports in the US where the aircraft are subjected to positive ATC, i. e., the aircraft need ground control clearances to operate. Class B airspace includes all airspace around these airports from the surface up to 12 000 MSL and spreads out to about 30 nmi.
- Class C: Class C airspace exists around 120 airports in the US that have control towers and radar approach control. This class of airspace has two concentric circular areas with a radius of 5 and 10 nmi around the airport, and extends up to 4000 ft above ground level (AGL).
- Class D: Class D airspace is a circular area of radius 5 nmi around the airport and extends up to 2500 ft AGL at airports with an ATCT.
- Class E: Class E airspace covers the volume of airspace below the class A airspace from surface to 18 000 ft MSL, and excludes airspace covered by classes B, C, and D.

67.1.1 Air/Ground Communications Systems and Functions

Today the ATC communications are primarily two-way voice capabilities over a radio system, which allow the controllers and pilots to coordinate tactical flight maneuvers needed for safety. Fundamental to the communication is the spectrum that supports it. For the ATC communications, this spectrum is coordinated worldwide, and is defined in several distinct bands, each used for specific purposes. Due to its long-range propagation characteristics, HF communications at frequencies between 3 and 30 MHz have been used in oceanic and remote polar operations for many years. VHF spectrum in the 117.95–137 MHz band is set aside for operations in well-traveled airspaces that use a line-of-sight radio infrastructure. Additional frequencies are set aside for satellite communications, defined and protected for aeronautical communications in the 1.5 and 1.6 GHz bands [67.4].

In the US, a network of VHF radio sites, shown in Fig. 67.2, provides the terrestrial infrastructure over which the voice communications operate. Specific frequencies in the band are provisioned to avoid interference between the operating airspaces, based on

(67.1), that governs the radio line-of-sight distance (D) from the aircraft to the radio horizon

$$D = K\sqrt{h}\ , \tag{67.1}$$

where $D =$ distance (in nautical miles), $h =$ height (in feet) of the aircraft station, and $K = 1.23$, a constant corresponding to an effective Earth's radius of $4/3$ of the actual radius.

These voice channels either support a single operational ATC position on a specified control frequency, providing half-duplex party-line communications among the controllers and the pilots in a specific airspace, or provide one-way broadcast information for weather or traffic conditions on designated information frequencies, as shown in Fig. 67.3. Air-to-air and emergency frequencies are also specially provisioned for in the VHF band. A continuously monitored emergency frequency has been established worldwide at 121.50 MHz, and an air-to-air channel has been designated for use at 123.45 MHz.

Beyond today's voice communications, digital technologies are used for data links in the ATC environment, allowing for data communication from an automated ATC system, that can closely integrate and incorporate directly with the aircraft systems. One of the first aeronautical communication data links to operate was the aircraft communications addressing and reporting system (ACARS) introduced in the late 1970s. The ACARS operates at 2.4 kbps, and provides short messages indicating aircraft on, out, off, in (OOOI) events relating to the aircraft leaving the gate, taking off, landing, and arriving at the gate, to help airlines manage their aircraft. This system also operates in the VHF band, and has been expanded to include more applications, including a predeparture clearance (PDC) function for ATC and a digital broadcast automated terminal information service (ATIS). Succeeding ACARS, a digital link, called VHF digital link (VDL) mode 2, was defined and standardized through the ICAO, to provide more capacity and higher speed (31.5 kbps) for airline and ATC operations. Other data link systems that have also been defined and standardized through the ICAO include:

- VDL mode 3, which integrates a digital ATC voice capability with the data link
- VDL mode 4, which can also provide surveillance functions
- Mode-S data link, which integrates data communications with the surveillance information such as from automatic dependent surveillance-broadcast (ADS-B).

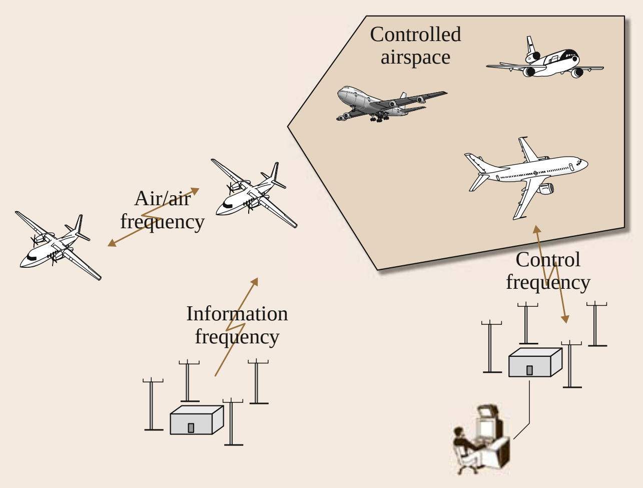

Fig. 67.3 VHF communications environment

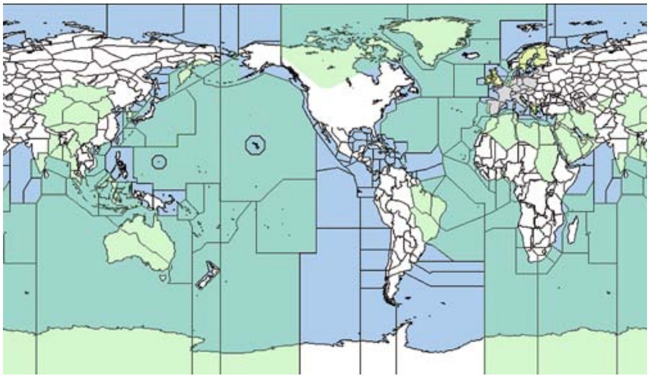

Fig. 67.4 Worldwide SATCOM use in ATC – *shaded in green*

In the 1990s, worldwide satellite communications networks for aviation first became available through the commercial satellite service providers, including Inmarsat and Iridium. Satellite communication is displacing the long-range HF voice communications for ATC in many areas of the world and is also providing reliable long-range data links in low-density air traffic environments, such as oceanic airspace as shown shaded green in Fig. 67.4.

New air/ground communications capabilities will provide faster and greater information sharing among ATC systems and aircraft using the above technologies, thereby improving the safety and efficiency of air traffic operations.

As new digital radio communications systems enable aircraft's control processors to coordinate information with the ground control systems, radio communications will become an even more critical component of managing air traffic control.

The air/ground communications system is a critical component of the ATM system, because it provides aircraft control information (e.g., instructions and clearances to the aircraft) and in some cases feedback information (e.g., aircraft position to the ground) to allow safe and efficient transit of air traffic through an airspace. Depending on the operational environment and specific equipment being employed, other functions and information can be provided over the communications systems, such as broadcast information to the pilots on local terminal weather conditions and runway operations, meteorological information for weather models or pilot-reported turbulence information. Given the ability of an aircraft to operate anywhere in the NAS, the systems on an aircraft must be able to interface with the ATM system, and the pilots must interact with the ATC system wherever they fly.

67.1.2 Navigation and Guidance Systems

Until recently, the VOR/DME or the VOR tactical air navigation (TACAN) (VORTAC) system has been the primary guidance system for navigation. Because of its line-of-sight limitation, the VOR/DME navigation is not available everywhere in the NAS, especially in remote mountain, polar, and oceanic regions. With the availability of broadcast signals from Earth-orbiting satellites as a part of global positioning system (GPS), aircraft equipped with GPS receivers can navigate point-to-point anywhere.

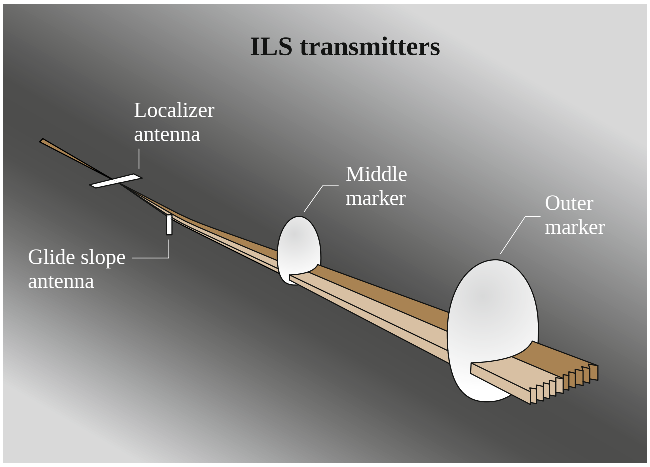

Fig. 67.5 Instrument landing system (ILS)

VOR/DME Navigation Systems

The VOR/DME [67.5, 6] is a short-range navigation system that has been internationally standardized and is in use throughout the world. To achieve a common civil–military system for en route navigation in the US, the distance measurement element of VOR/DME is provided by the military tactical air navigation (TACAN) system. The collocation of VOR and TACAN constitutes a VORTAC ground facility, providing VOR-bearing information to civil users, the TACAN-bearing information to the military aircraft, and distance information to both. At present, there are 775 VORTAC facilities in the US, 145 VOR/DMEs, and 90 VOR-only ground stations. A few more VOR ground stations have been procured by individual organizations that add to the total number of VORs listed above.

The VOR system has been the standard air navigation system to provide aircraft with bearing information with respect to a ground station. The VOR ground station transmission is in the VHF band from 108 to 117.95 MHz, divided into 50 kHz channels modulated by a 30 Hz signal and by a subcarrier of 9960 Hz, which is frequency-modulated (FM) at 30 Hz. The phase of the two 30 Hz signals is adjusted such that the phase coincidence occurs at magnetic north.

The VOR receiver employs a simple superheterodyne front-end followed by an envelope detector and narrow-band filters to separate the individual signal components. The FM signal is demodulated to recover the 30 Hz signal, and the two 30 Hz signals are applied to a phase comparator. The phase difference between these signals corresponds to the magnetic bearing of the aircraft from the ground station. A course selector (i. e., phase shifter) is added to one of the inputs to the phase comparator to permit the pilots to select any desired bearing between 0 and 360°.

The DME system is an electronic range measuring system which provides slant range information to the aircraft. DME is a two-way ranging method with a ground station operating as a transponder. The airborne interrogator transmits pulse pairs at a given ground station frequency and pulse-pair spacing. The ground station detects the presence of the pulse pair when it exceeds some detection threshold. The time of detection of the half-voltage point on the first pulse is used as a time reference for reply. A fixed 50 μs delay is introduced to account for internal delays. This delay can also be used to provide an electronic offset of the

DME zero range. The reply pulse pair is translated in frequency by 63 MHz. The interrogator determines its slant range by measuring the time between transmission and reception. The interrogator's transmissions are randomized to permit separation of its range data from that of the other interrogators.

Instrument Landing Systems

The ILS is a radio navigation system that provides an equipped aircraft with the horizontal and vertical guidance required for conducting precision landing approaches to the runways in lower-visibility conditions. As shown in Fig. 67.5, the ILS consists of two directional transmitters with a localizer and a glide slope aligned with the runway centerline. The horizontal guidance is provided by a VHF band localizer and the vertical guidance is provided by an ultrahigh-frequency (UHF) band glide slope transmitter. The distance information is provided by the DME, or by low-frequency (LF) marker beacons located at a certain distance from the runway end (threshold), as shown as middle and outer markers in Fig. 67.5. In the NAS, there are approximately 715 airports capable of providing precision instrument approaches. There are three categories of ILS equipment used under different levels of visibility conditions, depending upon when the pilots can see the runway (lights) from a certain height above the ground, called the decision height:

- Category I: Visibility minima as low as 1/2 statute mile within 200 ft (60 m) height above touchdown
- Category II: Visibility minima as low as 1/4 statute mile within 100–199 ft (30–60 m) height above touchdown
- Category III: Visibility minima potentially as low as zero feet within 0–99 ft (0–30 m) height above touchdown.

Although the ILS has proven to be a safe and effective landing aid worldwide, the technology has a number of limitations. First, it is relatively expensive to purchase and install the equipment. The antennae require large clear areas free of metal or metallic reflections, i. e., aircraft taxiing on the airport must be restricted in their position in order to avoid interference with the ILS signal. The ILS equipment must be routinely checked in flight to ensure that it meets the required specifications.

Satellite Navigation Systems

There are currently two satellite navigation constellations: the US GPS and the Russian global navigation satellite system (GLONASS), although only GPS is widely used outside of Russia. The implementation of the third and fourth constellations, GALILEO and COMPASS are currently being planned by the European Union and China respectively. Only GPS is discussed in this section, since it is the only operational system widely used by civil aviation.

Each satellite from these constellations continuously broadcasts a signal that carries ephemeris information allowing an accurate calculation of the satellite position and a code allowing for the accurate measurement of the signal propagation time from the satellite to the aircraft. A suitably designed receiver can acquire and track this signal and use the broadcast information, as well as so-called pseudorange measurements derived from the signal propagation time, to compute an accurate position solution every second. Such position solutions, however, do not meet all aviation requirements because their integrity is not assured. Integrity is a measure of trust in relying on the accuracy of the navigation system information, where the system alerts the user when the system is unable to contain the position error within an acceptable limit for safe operation. Several forms of *augmentation* have been developed in order to obtain the integrity required for aviation. Forms of augmentation that are currently used include a receiver-based technique called receiver autonomous integrity monitoring (RAIM) or aircraft-based augmentation system (ABAS), which uses redundant information from the number of satellites in view to ensure the integrity of the position solutions. Two other augmentation systems are the satellite-based augmentation system (SBAS) and the ground-based augmentation system (GBAS). Each system uses a ground infrastructure to derive corrections and integrity bounds for the satellite signals. The SBAS and GBAS differ in the type of correction and integrity information, as well as the means used to communicate that information to the user receivers. The SBAS is intended to provide service over wide areas and broadcasts the information from the geosynchronous satellites. The GBAS is intended to provide service over terminal areas by broadcasting the information from VHF ground transmitters. A hybrid augmentation system called ground regional augmentation system (GRAS), currently being developed in Australia, provides navigation service over wide areas using a network of VHF ground transmitters.

There are three main types of aircraft receivers for GPS and augmentations. These receivers provide position solutions to other parts of avionics, such as the flight management system (FMS) and the *navigators*,

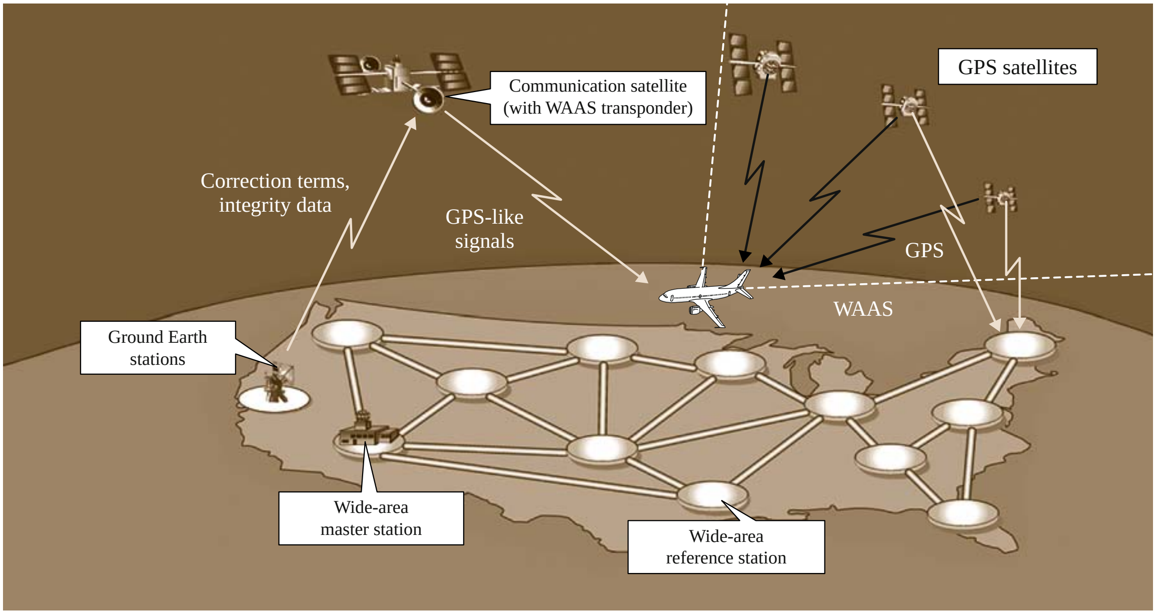

Fig. 67.6 The wide-area augmentation system (WAAS)

which include displays and controls that provide navigation guidance information to the pilots. Certified aircraft GPS receivers with RAIM can be used for en route navigation, terminal area navigation, and nonprecision approaches for landing operations. In addition, the SBAS aircraft receivers can be used for vertically guided approach and landing operations, called the procedures with vertical guidance (APV) approaches. The primary APV in the USA is the localizer performance with vertical guidance (LPV) approach. GBAS aircraft

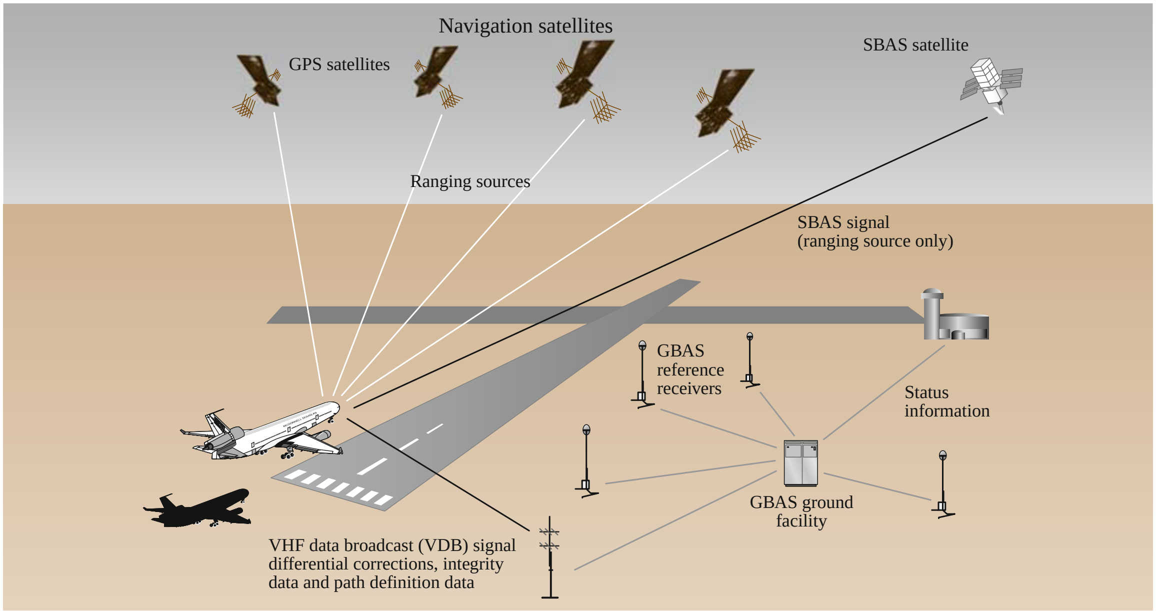

Fig. 67.7 The local-area augmentation system (LAAS)

receivers can be used for category I precision approach operations in addition to the terminal area navigation.

The SBAS uses a network of ground stations to receive GPS signals. The signals are forwarded to a master station, where atmospheric and other errors are identified, and a grid of corrections is created. This grid is transmitted to the user through a geosynchronous satellite. The user receiver can then interpolate between the corrections and improve the accuracy and integrity (i. e., the assurance, within specifications, that the navigation position is free from error) of the GPS signal. US operations use a wide-area augmentation system (WAAS), which can provide corrected horizontal and vertical guidance throughout the USA and parts of Canada and Mexico. WAAS was commissioned in 2003. A schematic of WAAS is shown in Fig. 67.6. The Japanese have developed the multifunction transport satellite (MTSAT) satellite-based augmentation system (MSAS), which is an SBAS that provides coverage in the Asia–Pacific region. Similarly, the European Union has developed the European geostationary navigation overlay service (EGNOS) that provides SBAS coverage over Europe and Africa. MSAS was commissioned in 2007 and EGNOS is expected to reach initial operational capability in 2009. The Indian government is developing the GPS and GEO augmented navigation (GAGAN) system, which will provide SBAS coverage over the Indian subcontinent. All of these SBASs are being developed under common international standards, so the receivers will be able to use any one of these systems.

The GBAS uses a ground station located on or near the airport to receive the GPS signals and to correct for errors. The correction information is forwarded directly to the aircraft via a VHF data link. The US GBAS system is called the local-area augmentation system (LAAS) and is shown in Fig. 67.7. Since the GBAS or LAAS station is located on the airport and near the approach path, there is no interpolation required. The LAAS may have the potential to provide category III service for the approach and landing, while the WAAS will be restricted for landing guidance to category I service. Air Services Australia is also developing a GBAS for certification in 2009.

67.1.3 Modes of Navigation

VOR/DME Mode of Radial Navigation

There are three types of VOR/DME facilities in the US. The difference among the facilities is related to the volume of airspace around each facility that is protected from interference from another facility. This airspace is known as the standard service volume (SSV). The three types are listed below:

- Terminal (T): 25 nmi radius from 1000 to 12 000 ft
- Low (L): 40 nmi radius from 1000 to 18 000 ft
- High (H): 40 nmi radius from 1000 to 14 500 ft, 100 nmi radius from 14 500 to 18 000 ft, 130 nmi radius from 18 000 to 45 000 ft, 100 nmi radius from 45 500 to 60 000 ft.

Coverage below 1000 ft is defined for reduced radii that are altitude dependent. Only H and L facilities are used for en route navigation. All facilities may be used for terminal area maneuvering and nonprecision approaches. Within the SSV, the pilots are assured of a signal with adequate power protected against interference from other facilities transmitting on the same or adjacent frequencies.

The present NAS en route navigation procedures for a majority of aircraft involve flying along VOR radials in or out of the ground station. The low-altitude victor airways and the high-altitude jet routes are defined by these radials like the highways in the sky.

Flights at or above 24 000 ft MSL are not authorized without a DME whenever the instrument flight rules (IFR) require VOR equipment (US regulations permit substitution of an approved GPS receiver for a DME receiver in most cases). The DME equipment is installed in most commercial aircraft and in a large percentage of corporate and some general aviation aircraft. Smaller aircraft flying at lower altitudes may not need a DME. Also, many aircraft owners are replacing DME receivers with GPS receivers.

Area Navigation (RNAV) and Required Navigation Performance (RNP)

The RNAV mode of navigation permits aircraft with appropriate equipment to fly any desired path from point to point without the need to overfly ground stations within the coverage of the station limits using either VOR/DME or DME/DME guidance.

RNP provides additional assurance of adherence to the desired navigation path. The US is planning to transition to full RNAV operations, with RNP operations where beneficial.

DME/DME RNAV is considered possible in those areas where the radii defining the DME arcs from at least two stations intersect at an angle between 30 and 150°. RNAV using DME/DME is more accurate than RNAV using VOR/DME, particularly at long ranges. The DME/DME-RNAV is feasible over most of the

USA, although some areas will not have appropriate coverage using DME/DME at some altitudes. Aircraft using satellite navigation have service available over the entire USA and can fly RNAV routes and procedures anywhere in the USA.

Approach and Landing

The instrument approach procedures to a runway involve landing during instrument meteorological conditions (IMC), and allow the approaches to be abandoned when a landing cannot be completed, such as when the weather is too bad to land, another aircraft is on the runway, or some other reason. The instrument approaches are generally divided into two categories: nonprecision approaches, which have only horizontal guidance; and vertically-guided approaches, which have both horizontal and vertical guidance. In a nonprecision approach, the aircraft flies along a published path and descends to remain above the published minimum altitudes during the approach. The aircraft uses its barometric altimeter to determine the minimum altitudes. The last segment of the approach is called the *final segment*. The final segment starts at the final approach fix (FAF), continues to a missed approach point (MAP), and is usually aligned with the centerline of the landing runway. The pilot is required to see the runway visually prior to landing. For a nonprecision approach, the aircraft departs the final approach segment and flies along the published horizontal path. The pilot descends to the published minimum altitudes. When the runway is in sight, the aircraft continues to land. If the runway is not in sight by the MAP, then the aircraft executes a missed approach. After a missed approach, an aircraft may attempt another landing approach, or may proceed to an alternate airport. Nonprecision approaches can use VOR, NDB, or the global navigation satellite system (GNSS), of which the US GPS is currently the only operational component for civil aviation.

For a vertically-guided approach, the aircraft departs the final approach fix, but has a vertical and horizontal guided path. Vertically-guided approaches typically align the aircraft on a stabilized glide path, and allow the aircraft to continue on the stabilized path until just before landing. The stabilized vertically guided approach is generally considered superior and safer than the nonprecision approach, which often require vertical maneuvering when the aircraft is near the runway, such as after the runway has been acquired visually by the pilot.

Studies have shown that the controlled flight into terrain (CFIT) accident rates are lower for the vertically guided approaches than for the nonprecision approaches. In addition, the visibility minima for vertically-guided approaches are also generally lower. This has led to a general desire to provide vertically-guided approaches (both APV and precision approaches) to all or most runway ends in the US.

Many commercial aircraft have GPS receivers and sophisticated barometric vertical guidance systems. These aircraft can fly lateral/vertical navigation (LNAV/VNAV) and RNP approaches, using GPS for horizontal guidance and approved barometric vertical navigation approaches for vertical guidance. The LNAV/VNAV approaches do not have sufficient accuracy or integrity to meet Category I minima, but do provide useful vertical guidance. The US has published over 1577 LNAV/VNAV and 234 RNP approaches, primarily to the runways serving commercial aircraft (as of January 2009).

The augmentation systems discussed earlier have the potential to provide vertically guided approaches to more airports and runways at a lower cost. Currently, an ILS must be installed on each runway end where vertical guidance is desired. However, approaches using GPS/barometric vertical navigation, LNAV/VNAV, or WAAS may be permitted without any ground navigation infrastructure. In addition to the LNAV/VNAV, the FAA is currently developing LPV approaches to most instrument runways. The LPV approach is primarily a WAAS vertically guided approach, and has a requirement of visibility minima equivalent to an ILS category I approach. The FAA has published over 1445 LPV approaches (as of January 2009), and plans to publish approximately 300 LPVs per year.

The LAAS system will use the GNSS landing system (GLS) approach. The GLS approach is equivalent to a category I ILS approach, but could also attain category II and category III performance. One LAAS station can serve each runway end at the airport, so there is a potential for reducing the ILS infrastructure and saving costs with LAAS. The LAAS system has not yet been commissioned, so no GLS approaches have been developed at this time.

67.1.4 ATC Surveillance Systems and Aircraft Tracking

ATC surveillance refers to the process of determining where aircraft currently are in a given volume of airspace. *Aircraft tracking* refers to the process of correlating successive measurements of various aircraft positions with the identified flights, thereby forming a history or *track* of positions, where each flight has recently been. Time-averaging the successive changes in a given aircraft's track position yields an estimate of that aircraft's current velocity as well. Given the aircraft's current position and velocity, its next position can be predicted for the purpose of surveillance data correlation.

ATC Surveillance Radar Systems

ATC surveillance systems locate weather and aircraft, which enable the ground controllers to separate aircraft safely by providing pilots with surrounding aircraft and weather advisory information. They involve both the ground and aircraft components. Two types of systems are currently used for aircraft surveillance:

- Search or primary radar (radio detection and ranging)
- Beacon or SSR.

The primary radar is so called because it was the first radar system developed and fielded for ATC. The secondary radar was the second radar system developed and fielded, and is used as the major radar for ATC surveillance today. Whenever the secondary radar fails, the primary radar serves as a backup. The primary radar also fills in the coverage for secondary radar dropouts. The primary radars detect two-dimensional (2-D) horizontal position of aircraft by sensing radar energy reflected from the surface of the aircraft. Although the primary radars provide aircraft position in terms of range and azimuth, other relevant data about an aircraft's identification and its altitude are not available. The primary surveillance is noncooperative, i. e., it detects aircraft position without the aid of an aircraft-based transmitter/receiver unit, termed a *transponder*. The primary surveillance systems are used to detect all airborne objects, including aircraft with such failures as loss of electronic power or failure of the transponder.

The secondary surveillance came about in an attempt to overcome some of the limitations and deficiencies of primary surveillance. The secondary surveillance is cooperative, because it requires the aircraft transponders in order to detect aircraft, to positively identify aircraft, and also to receive altitude reports of aircraft, depending on the transponder mode. The SSR requires the aircraft to be equipped with a transponder. The SSR ground station transmits radio frequency at 1030 MHz pulses from a rotating antenna. Upon receiving the ground signal, the transponder transmits a reply on a different frequency 1090 MHz. The aircraft range (ρ) and bearing (θ) are determined from the time delay and radar antenna direction [67.7]. Most airports and TRACONs in the USA use short-range radar or an airport surveillance radar (ASR). These radars provide surveillance coverage up to 60 nmi and 30 000 ft. The ARTCCs use air route surveillance radars (ARSR), which have a range of about 200 nmi and coverage up to 60 000 ft. A mode C transponder transmits altitude information.

The digital terminal radars using monopulse technology are ASR-11 and mode select sensor (mode S), and the en route ARSR are ATC beacon interrogators (ATCBI-6). The terminal radars provide position information updates every 4–5 s, and the en route radars update every 10–13 s. Generally the primary radar and the SSR antennae are collocated to detect 2-D aircraft positions consistently. The primary airport surveillance is provided by an airport surface detection equipment (ASDE-3), and the secondary surveillance by ASDE-X using multilateration techniques.

Ground Automation Systems and Functions

The en route and terminal automation systems convert target position (ρ, θ) into Cartesian coordinates, and correlate targets with the aircraft tracks. A track maintains state data for an aircraft across the radar scan updates. The tracker derives additional data such as the aircraft ground speed and heading for display. The velocity (speed and heading) information is also used in the aircraft track prediction, and by higher-level automation functions such as conflict alert (CA) and minimum safe warning altitude (MSAW), discussed later. The tracks can be automatically or manually initiated by the controller. All IFR aircraft are required to file a flight plan. When there is flight plan data available in the system, a track is automatically associated with the flight plan so that the flight data, such as the aircraft identification, is included with the speed, heading, and altitude in the displayed alphanumeric tag (in the form of a data block on the controller's display). If a target correlates with a track, the target position is used to update the position of the display symbol, which the controllers use for aircraft separation. If no target information is received in a scan, then the predicted track position is used to update the aircraft position on the display.

The terminal automation system initially included only single-radar displays, where all target data were received from only a single controller-selected radar site. The latest automation system upgrades provide a mosaic display selection to the controllers. The mosaic partitions the surveillance area into a grid with different cells assignable to different radar sites. The en route automation system includes an ARTCC facility-wide mosaic display. The automation system processes digitized radar weather messages and handles display formatting. The map messages are converted into display messages with x, y coordinates, and transmitted to the display channel along with the radar flight target data for display.

67.1.5 Aircraft Tracking

The ground ATC automation system provides aircraft position, velocity, and altitude information to the controllers to help them ensure safe separation between aircraft based on established separation minima. These minima are based on the accuracy and frequency or update rate of aircraft position data and altitude displayed to the controller. Moreover, each aircraft must be positively identified and accurately displayed. The NAS tracking system and the automated radar terminal system (ARTS), as a part of en route and terminal automation systems, respectively, process radar position inputs to track aircraft and display information to the controllers.

The aircraft tracking function computes the position and velocity of all tracked aircraft within the ARTCC's radar coverage, and provides the means for maintaining identity information (in alphanumeric form) with the appropriate search and beacon radar targets on the radar controller's display. Because of the cooperative nature of ATC, flight plan information concerning the planned route of flight, aircraft speed, altitude, and assigned beacon identity code are used in the processing by this function. The current tracker used in both the en route and terminal automation systems is a linear α, β tracker. With the position update rates mentioned earlier, the tracker lags in detecting positions accurately during aircraft maneuvers. The future automation system enhancements will include a seven-state interactive multiple model (IMM) Kalman filter tracker including x, y, z, $\dot{x}$, $\dot{y}$, $\dot{z}$, and turn rate to improve accuracy of position and velocity determination not only during straight and level flight, but also during maneuvers.

The accuracy of position and velocity determination by the tracking function is crucial in maintaining the desired separations between aircraft. Thus, in the future, as the aircraft surveillance and tracking accuracy improve, they could support reduction of minimum separation requirements, thereby not only helping to maintain safety but also to increase airspace/airport capacity. The ongoing deployment of standard terminal automation replacement system (STARS) uses a multisensor (instead of a single sensor in ARTS) IMM Kalman filter tracker to significantly improve the accuracy of position and velocity estimation.

Automatic Dependent Surveillance–Broadcast (ADS–B)

The radar systems discussed above provide independent surveillance for detecting aircraft. In order to enhance not only the accuracy of position/velocity determination, but also to increase coverage NAS-wide (current limitation of radars in remote/mountain areas in the USA), the ADS-B system provides cooperative surveillance by broadcasting the GPS-derived position information once every second using onboard navigation equipment. The ADS-B broadcasts include aircraft identification, position, velocity, and intent (future aircraft positions) within 100 nmi. Other aircraft equipped with an ADS-B receiver can process and display the aircraft in their vicinity on a display called the cockpit display of traffic information (CDTI). The ADS-B receivers on the ground can also receive the aircraft broadcast information. The large commercial aircraft use a 1090 MHz mode S extended squitter, and the smaller high-end general aviation aircraft use a universal access transceiver (UAT) 978 MHz for transmitting ADS-B information. The aircraft and the ground stations receive information from all line-of-sight aircraft.

ADS-B is currently being used in the State of Alaska, where there is limited radar coverage. Efforts are underway to provide ADS-B information along the US east coast from New Jersey to Florida. In spite of higher accuracy and update rate, the use of ADS-B as a single surveillance system has limitations. Any loss of, or errors in, the GPS signals could adversely impact the aircraft detection. Therefore it is also necessary to continue using primary and secondary surveillance radars complemented by ADS-B. The future automation and tracking system will derive a unique single track for each aircraft using ADS-B and radar measurements by using data fusion techniques.

67.1.6 Air Traffic Management Functions

Traffic Flow Management

The TFM function is responsible for managing the NAS airspace/airport capacity resources by efficiently balancing the demand for air traffic services with available system capacity. The TFM monitors expected demand to produce safe, orderly, and expeditious flow of traffic to minimize delays due to congestion and adverse weather. The ATCSCC has the authority to direct strategic planning of TFM initiatives on a national basis, and is the final approving authority for all regional interfacility TFM initiatives. It has four key responsibilities:

- Monitor air traffic demand, status of airports and airspace, and forecasted weather across the USA
- Coordinate with regional and local facilities to plan and implement traffic flow constraints (aircraft ground delays, ground hold/stops, altitude restrictions, rerouting etc.)
- Assess NAS performance for long-term improvements
- Provide a central point of contact for the NAS users.

The TFM initiatives include:

- For more than 6 days in advance, plan strategies to identify long-term system demands and airspace choke points, as well as recommend operational and procedural changes
- From 6 days to 1 day in advance, predict near-term traffic loads and use weather forecasts to develop strategies for balancing traffic demand and capacity
- On the day of operations, analyze the impact of planned constraints based on flight schedules and predicted weather, as well as collaborate with the users for dealing with the constraints and demand/capacity imbalance
- After the day of operations, analyze the archived operations data to assess effectiveness of the traffic flow initiatives.

The regional (ARTCC) and local (TRACON) TFM functions deal with daily and hourly operations by balancing the demand with the predefined sector (segments of airspace within the jurisdiction of each facility) capacity.

As part of TFM automation, the enhanced traffic management system (ETMS) provides NAS-wide information on traffic loads at capacity-limited resources such as the airports, routes, route merge points (fixes), and airspace sectors. The two components of the TFM automation system are the traffic situation display, which provides a map-oriented display for showing aircraft positions, routes, and weather data, and the monitor/alert function, which alerts when the traffic demand in sectors or at fixes is predicted to exceed predetermined threshold values. A flight schedule monitor provides capabilities to predict airport congestion, and supports planning and monitoring of ground delays as a part of ground delay program (GDP).

Air Traffic Control Services

The primary task of the ATC function is to safely guide and separate aircraft flying under IFR, i. e., monitor and maneuver aircraft to keep them separated by the established separation minima and provide navigation guidance in the airspace where there is no navigation coverage. The following are specific clearances issued by the controllers to service flights from gate to gate:

- Taxi/runway assignment: when the aircraft is ready to depart, the ATC function issues a clearance for the aircraft to start taxiing on an assigned taxiway and wait before the entry to the assigned runway with a clearance to take off. Similarly the aircraft are given landing clearances to specific runways.
- Departure/arrival guidance: unless the aircraft are capable of flying RNAV procedures from/to the airports, the controller provides navigation guidance in the airspace around the airport where there is no navigation guidance available in the form of *vectors*. These are compass headings that the pilots are required to fly under ground system monitoring. In addition, the controllers issue altitude changes and speed adjustments to prevent conflicts by maintaining the required distance spacings between aircraft for safety. For departures, the navigation guidance is provided from *radar contact* (when an aircraft has been positively identified on the radar display) until the aircraft is able to navigate on its own. For arrivals, the guidance is provided from the entry into the terminal airspace, or from the termination fix of a standard terminal arrival route (STAR), to the final approach course for landing.
- Separation from other aircraft: once the aircraft are en route, the controllers ensure that each aircraft is safely separated from all other aircraft in accordance with the prescribed rules. When the desired minimum separation is expected to be violated, the controllers issue altitude/heading/speed clearances to increase separation.
- Safety alerts: controllers provide the aircraft with low-altitude or obstruction warnings based on information provided by MSAW; wake turbulence cautionary advisories, in case lighter aircraft are following a heavy aircraft; and information on hazardous weather, such as wind shear, using Doppler weather radars and low-level wind-shear alert system (LLWAS).

67.2 Functional Role of Automation in Aircraft for Flight Safety and Efficiency

As digital computers have become smaller, faster, more powerful, and more robust over the past decades, aircraft have benefited from their use in the cockpit to automate key functions. In the late 1970s and early 1980s, for example, automation was aimed primarily at reducing the pilot workload of managing complex aircraft systems such as electrical, hydraulic, fuel, and pressurization. This led to the elimination of the *flight engineer* position in the aircraft. Automation in modern aircraft has been effectively applied to enhance flight safety and efficiency. Although the enhanced ground proximity warning system and the predictive windshear detection system alert the pilots to stay away from the terrain and dangerous weather conditions, the traffic alert and collision avoidance system (TCAS) is the most significant capability in the cockpit for warning pilots about the presence of other aircraft in the vicinity.

The TCAS has its hardware and software integrated with the other systems in the aircraft cockpit. Its purpose is to avoid midair collisions, acting as a last-minute safety net when normal aircraft separation measures have failed. The TCAS issues radio interrogations that query ATC transponders carried onboard most aircraft. Measuring the time of the replies enables the calculation of each aircraft's slant range. The tracking of an aircraft's slant range every second yields the aircraft's closure rate. The reply also provides the aircraft barometric altitude, which can be compared to that of its own.

There are two different versions of TCAS for use on different classes of aircraft. The first, TCAS I, indicates the bearing and relative altitude of all aircraft within a selected range (generally 10–20 miles). With color-coded symbols and aural alerts, the display indicates which aircraft pose potential threats. This constitutes the traffic advisory (TA) portion of the system. TCAS I does not offer solutions to resolve the conflicts, but does supply pilots with important data so that they can determine the best course of action. The determination of a potential collision threat is time based, rather than based on a fixed distance, as is used by the ground automation functions. The calculation of the time to potential conflict τ is given by

$$\tau = \frac{-(r - k^2/r)}{\dot{r}}\,, \tag{67.2}$$

where r is the tracked range, $\dot{r}$ is the estimated relative divergent range rate, and k is a constant for a given altitude. Another time calculation is used for the vertical plane.

TCAS uses a modified τ, which predicts the time to a specified minimum distance. This distance allows for some lateral acceleration, without which TCAS could provide inadequate warning time.

In addition to a traffic display, the more comprehensive TCAS II also provides pilots with vertical resolution advisories (RA) when needed. The system determines the vertical profile of each aircraft during climbing, descending, or level phase of flight. The TCAS II then issues an RA advising the pilot to execute an evasive maneuver necessary to avoid the other aircraft in the form of *climb* or *descend*, or *limiting vertical rates*. If both aircraft are equipped with TCAS II, then their systems coordinate to ensure compatible RAs.

As the cost of fuel has risen, automation is also used to enhance the efficiency of flight operations by employing thrust and energy state management techniques. The FMS on a modern transport-category aircraft takes inputs from a wide range of sensors, and couples these with data from a comprehensive navigation and flight performance database. The FMS then generates an optimum flight profile in order to achieve the operator's objectives of minimizing direct operating costs, which are made up of flight time and fuel-related costs.

The FMS includes a flight management computer system (FMCS) coupled with a flight guidance system, a thrust management system, and an electronic flight instrument system (EFIS) to provide total flight management capabilities. The FMCS consists of two flight management computers (FMC) and multiple control display units (MCDU) to provide pilot interface for data entry/review. The FMC provides flight planning and performance management, navigation database storage and retrieval, precise navigation and guidance, and interface with other aircraft systems. Using the current computed vertical profile data from the performance function, the guidance function compares actual and desired altitude and altitude rate, and generates pitch and thrust commands as input to the flight guidance and control (autopilot) and thrust management systems, respectively. These systems include autopilots, flight directors, and an autothrottle. Each autopilot uses a flight control computer (FCC), which signals movement of aircraft ailerons and elevators. The autopilot captures and holds the selected altitude when in vertical speed, altitude change, or vertical navigation mode. The autothrottle adjusts the throttles to achieve the desired speed. The EFIS function of the FMC provides dynamic and background data to the EFIS symbol generator as well as selection of navaids.

The FMCS functions include:

- Flight plan management: provides on board flight planning from a global database including predefined routes.
- Guidance: by integrating precise position and onboard flight planning information, provides three-dimensional (3-D) navigation plus speed or four-dimensional (4-D) navigation including 3-D and time. Lateral guidance provides precise path control and smooth maneuvers at turning points. Vertical guidance provides precise vertical path control.
- Performance management: provides optimum speed, altitude, and thrust settings to minimize operational costs. A choice of economy or alternative flight modes is also available.

The aircraft operator, for example, can select at the outset what is most important to the airline's bottom line for that particular flight (operating at minimum fuel cost, operating with minimum flight time, or a *blend* between the two). The FMCS then determines the optimum vertical profile and speed schedule for the flight, taking into account all known factors such as en route winds, temperatures, and aircraft weight. The FMCS constantly refines its output to account for any change in actual winds or temperature. The wind field data that provides the FMCS with information on future waypoints is easily uplinked to the aircraft using an air–ground data link. If the flight is not constrained by the ATC restrictions, the flight profile dictated by the FMCS will be the optimum. In the case when the ATC constraints are imposed, the FMCS will still provide an optimum profile within those constraints.

In many implementations of the modern FMS, the management of the speed and altitude profiles effectively replace the shortcomings of the non-FMS relic of look-up performance tables and rules of thumb. The FMCS outputs can be fed directly to the aircraft autopilot/flight director system (APFDS), thereby reducing workload for the pilot and making him/her better aware of the progress of the flight flown by the automation system.

67.3 Functional Role of Automation in the Ground System for Flight Safety and Efficiency

In the ground automation system, two functions, MSAW and CA, provide safety alerts to the controllers in all ARTCCs and most TRACONS. The MSAW checks aircraft tracks for current and predicted conflicts with a terrain, and the CA checks for aircraft-to-aircraft conflicts. Both functions alert the controllers through display indications and audible outputs. The user request evaluation tool (URET) is an automation system deployed in the ARTCCs to detect potential conflicts 20 min in advance in order to help controllers take early decisions to resolve aircraft-to-aircraft and aircraft-to-airspace conflicts.

67.3.1 Minimum Safe Altitude Warning

The MSAW function is used to detect the proximity of aircraft to a terrain or surface obstructions. It uses two subfunctions for detecting hazards. One subfunction detects the proximity of an aircraft on the final approach for landing to the required minimum descent altitude or the decision height for the approach. The second subfunction is used to detect whether the aircraft is in hazardous proximity to a terrain outside the approach areas. The location of the aircraft is compared against an internally defined digital map containing the heights of the highest obstructions within the defined areas. When a hazard is detected, the automation system produces a visual alert by displaying a flashing symbol near the affected aircraft. The automation system also sets off an alarm when a hazard is detected.

67.3.2 Conflict Alert

The CA function detects an imminent loss of separation between two controlled aircraft that could lead to a potential mid-air collision. It can detect conflicts both for those aircraft that are traveling in a straight line and for those that are executing turns in a maneuver. When an alert is detected, the automation system displays a flashing symbol next to the positions of the aircraft that are in jeopardy. The CA function also sets off an aural alarm to warn the controller that a conflict has been detected.

Potential conflicts, defined by a horizontal separation parameter and an altitude separation parameter, are detected by projecting a volume of airspace constructed about each track along its velocity vector from its present position to a position some time in the future. En route CA function typically uses a horizontal parameter of 4.8 nmi, an altitude of 1000 ft, and a projection time parameter of 120 s. The corresponding terminal CA function uses the horizontal parameter of 1.2 nmi, 375 ft vertically, and a projection time of 40 s. The CA function considers only the aircraft tracked by the ground automation systems with valid altitude information. If another aircraft is found within the volume of the projected airspace for a given subject aircraft, a potential conflict is declared and an indication is given on the displays for the sector(s) controlling the aircraft.

67.3.3 User Request Evaluation Tool

The URET [67.8] replaces flight progress strips with electronic flight information, thereby reducing the need to maintain and mark strips. In addition, URET notifies the controllers of aircraft-to-aircraft separation problems and aircraft-to-special activity airspace problems.

The URET is a decision support function that combines real-time flight plan and en route automation track data with site adaptation, aircraft performance characteristics, and winds and temperatures aloft to construct four-dimensional (4-D) flight profiles, or trajectories for both predeparture and active flights. For the latter, it also adapts itself to the observed behavior of the aircraft, dynamically adjusting predicted speeds, climb, and descent rates based on the performance of the flight as it is tracked through the en route airspace. The URET's predicted trajectories are used to continuously detect potential aircraft conflicts up to 20 min into the future, and to provide strategic notification to the appropriate controllers. These trajectories also provide the basis for the NAS trial flight planning capability. The trial flight planning process allows the controllers to check if a desired change in an aircraft flight plan would result in potential conflicts with other aircraft later, before such a change in the flight plan is approved.

67.3.4 Traffic Management Advisor

The traffic management advisor (TMA) is a decision function supported by the en route automation in the ARTCCs to assist traffic management personnel and controllers in optimizing arrival traffic flows to capacity-constrained airports. The TMA uses aircraft trajectory models, real-time radar track data, flight plan data, and wind data updated every 12 s to compute optimal schedule arrival times at the TRACON entry (meter) fixes. The TMA algorithms consider IFR separation minima for the airspace and final approaches to the runways, desired airport acceptance rates, and other ATC constraints. They determine the delays for the aircraft while they are still in the en route airspace controlled by the ARTCC so that the desired airport acceptance rates are not exceeded.

The TMA is intended to enhance the efficiency of flight operations and increase throughput relating to airport capacity during periods of peak traffic demand [67.9]. The aircraft-specific time delays are displayed to the controllers. It is at the controller's discretion to maneuver the aircraft to achieve the required delays. The TMA is intended to help controllers land more aircraft per unit time, and redistribute the unavoidable delays for aircraft from the lower (near the airport) to higher altitudes in the ARTCCs for fuel efficiency and reduced direct operating costs. Additionally, the TMA is expected to reduce flight time for aircraft by reducing holding and vectoring outside of the TRACON airspace. This is achieved by coordinating and optimally sequencing flights to the runways arriving from different directions.

The MSAW and the CA functions have been implemented in both the en route and terminal automation systems for a number of years. The URET and TMA functions are being deployed, and all ARTCCs will have them in use in the near future.

67.4 CNS/ATM Functional Limitations with Impact on Operational Performance Measures

As stated earlier, the current CNS/ATM functions provide information to the pilots and controllers, and most of the decisions in the aircraft and on the ground are made open loop manually. The primary requirement is to conduct safe flight operations by following a set of separation rules either by maintaining a safe distance between the aircraft or safe altitude separation. The controllers manually trying to achieve these separations between aircraft by relying on tracked aircraft position and velocity information often permit larger separations

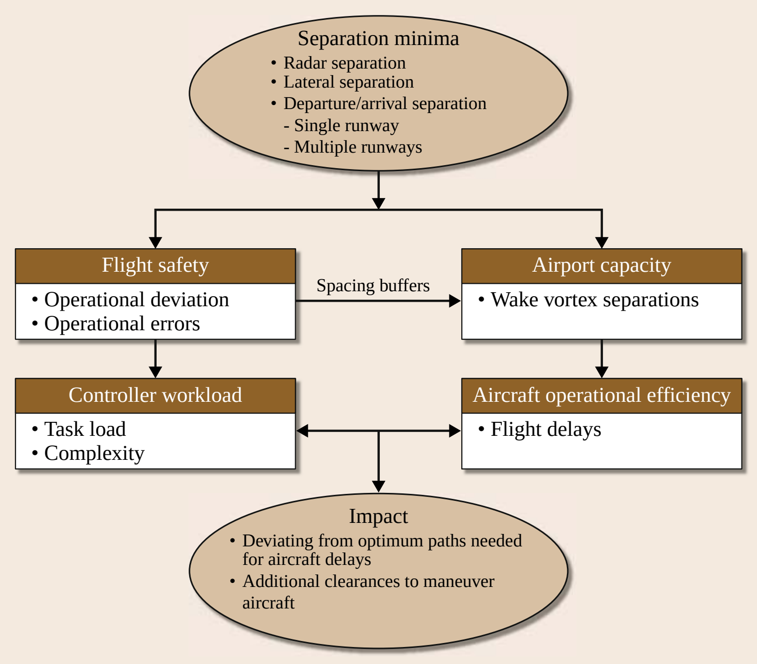

Fig. 67.8 Impact of separation minima on operational performance

than the required minimums by adding a safety buffer. The use of distance separations larger than the desired minimum reduces capacity, especially at airports. With fewer aircraft permitted to depart and land than the separation minima would otherwise allow, delays due to the reduced capacity add operating costs for the users. In order to delay aircraft in the air while trying to meet the safe separation objectives, the controllers deviate aircraft from their desired optimum paths by issuing additional clearances to maneuver the aircraft by changing their paths, altitudes or speeds. Any deviations from the desired minimum flight profiles increase workload for both the controllers and the pilots, who have to manually fly the aircraft during these maneuvers, while the controllers continue to monitor aircraft compliance to the changes.

Figure 67.8 illustrates the impact of separation minima on the operational performance measures relating to flight safety, airport capacity, aircraft operational efficiency, and controller workload, which are discussed below.

67.4.1 Current Separation Minima for Controlled IFR Aircraft

For all controlled aircraft using IFR, the radar-tracked position, velocity, and altitude information are used by the controllers to keep the aircraft separated using the separation minima rules presented in Table 67.1. The separation requirements apply in all controlled airspace, except during the departure and landing phases of flight. These are based upon the radar resolution accuracy and update rate in the horizontal domain, and on the accuracy of the altimeter in the vertical domain. In addition to the radar tracking capabilities, the longitudinal or in-trail separation minima on the final approaches also depend upon the aircraft wake turbulence. All aircraft generate a wake, which is a disturbance caused by a pair of counter-rotating vortices trailing from the wing tips. The strength of these vortices depends upon the size/weight of the leading aircraft and affects the trailing aircraft by imposing rolling moments exceeding the roll-control capability of the aircraft behind. Because of this wake turbulence effect, the controllers are required to use larger separations for trailing aircraft behind larger or heavier aircraft, including a Boeing B-757. These rules directly impact the capacity of the NAS [67.10, 11].

Minimum Lateral Separation between Adjacent Routes

Two aircraft navigating on different airways must have their route centerlines separated laterally by 8 nmi as long as the aircraft are less than 51 nmi from

Table 67.1 Separation minima

Flight phase	Separation minima	Requirements	Controlling factor
En route airspace	5 nmi horizontal	Below 60 000 ft, if multiple radar sensors (mosaic mode) used or either aircraft is more than 40 nmi from antenna, and 60 nmi if mode S surveillance is used	Radar resolution accuracy and update rate
En route path width	8 nmi	Adjacent route separation minima	Navigation mode and system accuracy
Terminal airspace	3 nmi horizontal	Below 18 000 ft, if radar in single-sensor mode and both aircraft within 40 nmi of antenna	Radar resolution accuracy and update rate
All airspace	2000 ft vertical	Above 29 000 ft	Altimeter accuracy
	1000 ft	Above 29 000 ft (RVSM*) or all aircraft at or below 29 000 ft	RVSM certified altimeter above 29 000 ft
Successive arrivals – Same runway or parallel runways spaced < 2500 ft apart	Longitudinal: 3.0 nmi	Radar in single sensor mode and both aircraft within 40 nmi of the antenna	Radar resolution accuracy and update rate
	2.5 nmi	On final approach, if runway occupancy time is 50 s or less and no wake turbulence effect	Runway occupancy time
	4/5/6 nmi	Behind a heavy aircraft or B757 (depends on trailing aircraft type)	Wake turbulence
Parallel approaches – Independent ILS approaches to dual runways	Simultaneous operations once established on final approach	Runways ≥ 4300 ft apart Require ASR	Blunder recovery
		Runways 3400–4300 ft apart Require final monitor aid or PRM	Radar resolution accuracy and update rate
		Runways 3000–3400 ft apart Require PRM and 2.5° localizer offset	Localizer resolution **
Parallel approaches – Dependent ILS approaches to dual runways	2.0 nmi diagonal between aircraft on adjacent runways	Runways ≥ 4300 ft apart	Blunder recovery
	1.5 nmi diagonal between aircraft on adjacent runways	Runways 2500–4300 ft apart	Wake turbulence is an issue below 2500 ft runway spacing
Successive departures – Same runway or parallel runways spaced < 2500 ft apart	1.0 nmi	Courses diverge by 15° or more (not behind heavy/B757)	Radar separation Wake turbulence
	2.0 nmi increasing to 3.0 nmi	Courses do not diverge	Radar separation
	Wake vortex separation: – Distance (see above) – Time (2 min)	Behind a heavy/B757 aircraft	Radar separation Wake turbulence
Simultaneous departures – Parallel or nonintersecting runways	Simultaneous operations	Parallel runways separated by 2500 ft or more and courses diverge by 15° or more	Radar separation Wake turbulence
		Non intersecting runways with courses diverge 15° or more	
Departure and arrival – Same runway	2.0 nmi increasing to 3.0 nmi	Within 40 nmi of the radar antenna	Radar separation Radar resolution accuracy and update rate
	2.0 nmi increasing to 5.0 nmi	Not within 40 nmi of the radar antenna	

Table 67.1 (cont.)

Flight phase	Separation minima	Requirements	Controlling factor
Departure and arrival – Same runway	2.0 nmi increasing to 3.0 nmi	Within 40 nmi of the radar antenna	Radar separation Radar resolution accuracy and update rate
	2.0 nmi increasing to 5.0 nmi	Not within 40 nmi of the radar antenna	
Departure and arrival – Parallel or nonintersecting runways	Simultaneous operations	Thresholds are even *** Runway thresholds are at least 2500 ft apart Missed approach and departure courses diverge by at least 30° Missed approach by a heavy jet cannot overtake departing aircraft	Radar separation Wake turbulence

* Aircraft equipped with required vertical separation minimum (RVSM) certified altimeter;
** RNAV/RNP arrivals may reduce lateral deviations and enable arrivals to runway with separation less than 3400 ft without the need to offset one of the approaches;
*** Staggered thresholds increase or decrease the runway separation required

a VOR/DME station. When the aircraft are more than 51 nmi from the navaid, the airways should diverge at an angle of 4.5° from the navaid. If both aircraft are flying in RNAV mode, a constant 8 nmi lateral separation could be maintained.

67.4.2 Flight Safety Assessment Metrics

In spite of millions of operations over the years, there have been an insignificant number (1198 from 1959 to 2006) of passenger aircraft accidents [67.12] as a result of controllers enforcing the above separation minima. US and Canadian operators were involved in only one-third of these accidents. However, due to system inaccuracies and human judgment, aircraft sometimes come closer to each other than the established separation minima. In order to minimize the number of separation violations, the controllers add an extra buffer to the desired separation, especially during the landing phase of flight where wake turbulence could be critical to aircraft safety. Even with the increased separation between aircraft due to the added buffer, there are still flights that occasionally end up with less than the desired minimum separations. In order to assess and analyze the causes of reduced separations, the following two performance measures are determined from the recorded operational data or controller/pilot reports [67.13]:

- Operational errors: an occurrence attributable to an element of the ATC system in which less than the applicable separation minima results between two or more aircraft, or between an aircraft and the terrain or obstacles (e.g., operations below the minimum vectoring altitude, equipment/personnel on runways, or aircraft lands or departs on a runway closed to operations after receiving air traffic authorization)
- Operational deviations: an occurrence attributable to an element of the ATC system in which the applicable separation minima, as referenced above, in the operational error were maintained, but the aircraft penetrated the airspace that was delegated to another airspace sector or facility without prior coordination and approval; or an aircraft, vehicle, equipment, or personnel encroached upon a landing area that was delegated to another position of operation without prior coordination or approval.

The ATC system continues to work on mitigating the causes of the above errors and deviations.

67.4.3 Determination of Airport Capacity

Even though the traveling public is the ultimate user of the NAS resources, from an operational perspective, what matters most is the actual number of flight operations that the CNS/ATM system is able to handle without delays. The separation rules no doubt are intended to ensure safety, but they also directly relate to airport capacity. These separation requirements limit the number of operations when the traffic demand is heavy. Often airspace congestion is caused by traffic demand exceeding the airport capacity. Consequently, maximum utilization of airport capacity is paramount to keeping the flight delays to a minimum. The allowable operations at an airport depend upon a number of separate elements including the surrounding airspace, the runways and taxiways, the gates and parking apron, and the terminal building (including ticket counters, security gates, and baggage claim areas). Any one of these elements could limit the number of passengers that can be accommodated per unit time (hourly, daily) at an airport.

The airport capacity is defined as the maximum sustainable runway throughput of aircraft arrivals and departures on a long-term basis, given continuous sustained traffic demand. Although the actual throughput may be different in a given hour, due to short-run variations in aircraft mix, control procedures, etc., the measure of theoretical capacity is relevant for comparison of operational performance at airports, or developmental alternatives to enhance capacity at a given airport. The following factors are part of the airport capacity estimation process [67.14]:

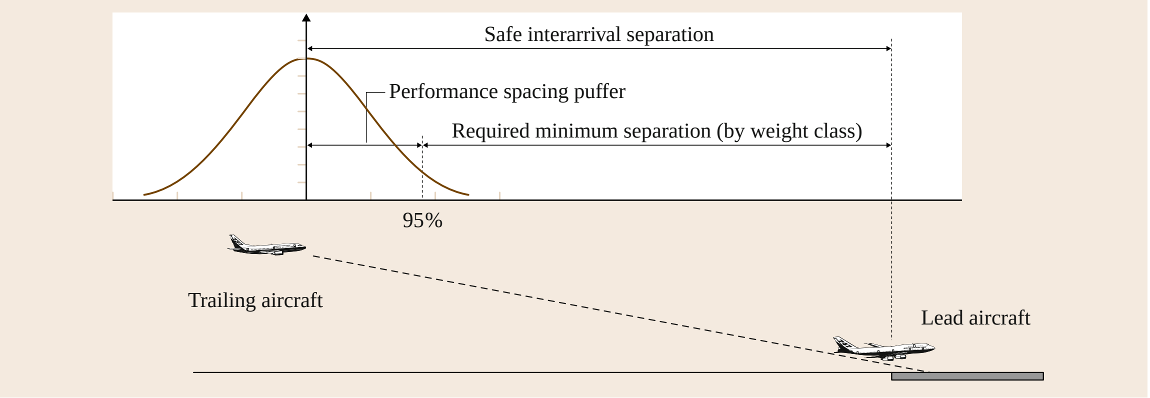
- Aircraft characteristics:
  - Final approach speed
  - Runway occupancy time (ROT) – mean and standard deviation (the ROT for arrivals is the average time interval from the time an aircraft crosses the runway threshold to the time when it exits the runway)
- Aircraft fleet mix (percentage of different aircraft types and/or weight classes)
- Separation minima (as discussed in Table 67.1):
  - Minimum arrival separations (arrival–arrival)
  - Minimum arrival/departure separation for the shared runway
  - Minimum departure separations (departure–departure)
  - Minimum interarrival separation (minimum required separation distance plus a performance buffer for safety)

Table 67.2 Wake vortex interarrival separation (nmi)

Arr–Arr separations at threshold					
		Leading aircraft type			
		Heavy	B757	Large	Small
Trailing	Heavy	4	4	2.5	2.5
aircraft	B757	5	4	2.5	2.5
type	Large	5	4	2.5	2.5
	Small	6	5	4	2.5
Aircraft weight classes					
Heavy	Maximum takeoff weight > 255 000 lb				
B757	Boeing 757				
Large	41 000–255 000 lb				
Small	≤ 41 000 lb				

- Relative percentage mix of arrivals and departures, or an arrival/departure ratio, for a given time period
- Performance spacing buffer.

As mentioned earlier, a buffer is added for safety to the required minimum separation distance between successive arrivals. This buffer reflects the variations in aircraft performance, as well as the manual control process for turning aircraft for the final approach. The buffer was estimated based on data collected in the USA in the 1970s, but is still used in estimating capacity for the airports. This buffer was determined to be a normally distributed interarrival error of 18 s (1σ) to reflect the spacing error at the threshold [67.14]. The mean interarrival separation is assumed to be 1.65σ above the minimum desired separations. This 5% approximation is a modeling construct only to account for a number of factors primarily relating to speed variability. It does not imply that 5% of the actual aircraft pairs in-



Safe interarrival separation
Performance spacing puffer
Required minimum separation (by weight class)
95%
Trailing aircraft
Lead aircraft

Fig. 67.9 Interarrival time determination

trail lack minimum desired separation. Although it is possible that the actual interarrival spacing could be represented by other distributions, the FAA airport capacity model has always used a normal distribution. The model is intended to provide an estimate of airport capacity for relative comparison purposes. It is not intended to estimate an actual controller's ability to achieve a certain level of arrival throughput. Table 67.2 shows the required separation minima between successive arrivals based on the wake vortex considerations for different weight classes of aircraft. Figure 67.9 shows the delineation of interarrival time (IAT) given by

$$\mathrm{IAT} = \frac{\text{Desired minimum separation} + 1.65\sigma}{\text{Final approach speed of trailing aircraft}}\,. \tag{67.3}$$

Airport Capacity for Arrival Operations on a Single Runway

The arrival capacity [67.15] is computed by determining the average time between successive arrivals, and inverting this time to find the maximum number of arrivals per hour

$$\begin{aligned}&\text{Capacity}\\ &\quad= \frac{3600}{\text{Average time separation between arrivals}}\\ &\quad= \frac{3600}{\mathrm{TAA}}\,.\end{aligned} \tag{67.4}$$

The required time separation for each aircraft class pair ($\overline{\mathrm{TAA}}(i, j)$) is determined by comparing the arrival runway occupancy time of the lead aircraft i and the IAT over the runway threshold for the aircraft pair ij, and selecting the larger of these two values. The frequency with which each aircraft class pair would occur is assumed to be the product of their individual frequencies, e.g., the frequency of occurrence of the class pair $i, j = \%i \times \%j/10\,000$. Therefore, the average time separation between arrival pairs is computed as the sum over all class pairs of the product of $\overline{\mathrm{TAA}}(i, j)$ and the frequency with which the pair is expected to occur

$$\mathrm{TAA} = \sum_{i,j} \overline{\mathrm{TAA}}(i, j) \times \%i \times \%j/10\,000\,. \tag{67.5}$$

In determining the arrival runway occupancy time and the landing time between arrivals, the airport capacity estimation process used is an airport capacity model (ACM) that considers the variability of aircraft, pilots, and controllers, as expressed by the standard deviations of arrival runway occupancy time and arrival–arrival time separation. In addition, to determine the time between arrivals over the runway threshold, the ACM considers the final approach velocities of the aircraft pair and the length of the common final approach path. If the velocity of the trailing aircraft is less than the velocity of the lead aircraft, the specified minimum arrival–arrival separation is considered at the merge point of the two approach paths.

Airport Capacity for Departure Operations on a Single Runway

The capacity of a departure-only runway is given by

$$\begin{aligned}&\text{Capacity}\\ &\quad= \frac{3600}{\text{Average time separation between departures}}\\ &\quad= \frac{3600}{\mathrm{TDD}}\,.\end{aligned} \tag{67.6}$$

The required time separation for each aircraft class pair ($\overline{\mathrm{TDD}}(k, l)$) is determined by comparing the departure runway occupancy time of the lead aircraft k and the time separation between departures (from the runway threshold) for the aircraft pair kl. The larger of these two values is assumed to be the required time separation at the runway threshold for this pair of departure aircraft classes. The average time separation between departures is computed as the sum over all class pairs of the product of $\overline{\mathrm{TDD}}(k, l)$ for each aircraft class pair and the frequency with which the aircraft class pair is expected to occur

$$\mathrm{TDD} = \sum_{i,j} \overline{\mathrm{TDD}}(k, l) \times \%k \times \%l/10\,000\,. \tag{67.7}$$

Airport Capacity for Mixed Arrival/Departure Operations on a Single Runway

To insert departures between arrival pairs, the airport capacity model imposes the following requirements:

- The departures cannot roll if an arrival is already on the runway
- The departures cannot roll if:
  - An arrival is within some specified distance of the runway threshold, or
  - The departure cannot clear the runway before the arrival comes over the threshold.
- The departure–departure separation minima must also be met to insert multiple departures between an arrival pair.

By employing these conditions, the model computes the probability of inserting one, two, or three departures between each arrival pair. The interleaved departure capacity is then determined from these probabilities and the aircraft mix.

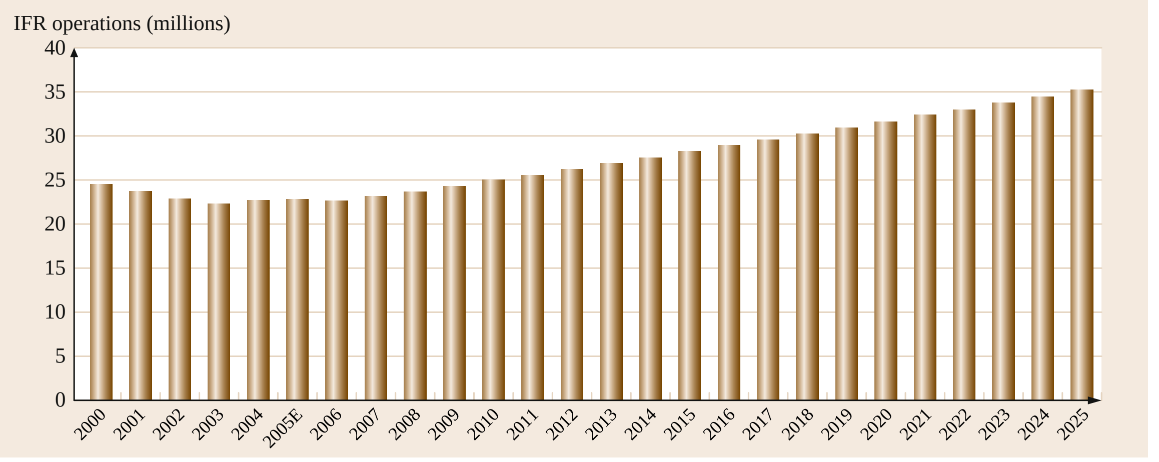


Fig. 67.10 Annual controlled aircraft operations

Airport Capacity for Dependent Arrivals and Departures on Two Runways

The model can also compute the capacity for a pair of runways when departures on one runway are dependent on the arrivals to the other runway. The departures cannot be released if an arrival is within a specified distance from the runway threshold, but can be released as soon as the arrival touches down. It is not necessary to wait until the arrival has exited the runway.

The logic for computing the departure capacity of this configuration is similar to that used for a single runway. After the interarrival times are obtained, the probability of performing one, two, or three departures in each interarrival gap is calculated. The departure–departure separation minima are enforced, not just between the departures in the same interarrival gap, but also between the departures in the adjacent gaps. This is rarely necessary for mixed aircraft operations on a single runway, because the time required for an arrival operation is usually greater than the departure–departure separation minima.

67.4.4 Aircraft Delays to Measure Operational Efficiency

Ideally all aircraft operators would like to fly the most wind-favored airway or a direct route if they are RNAV equipped, from the origination airport to the destination airport. This is generally feasible during light traffic periods when the airports are not operating at capacity. During medium to heavy periods of traffic demand, the airport capacity limits the number of departures and arrivals, which result in delays. As shown in Fig. 67.10, the number of annual controlled IFR aircraft operations (including air carrier, commuters, air taxi, and high-end general aviation aircraft) is expected to grow from a current 23 to 35 million by the year 2025. Unless means are explored to increase capacity, especially at the major airports, delays will continue to increase, thereby impacting the aircraft operational efficiency that will significantly increase the users' direct operating costs. Fig. 67.11 shows the increase in average delays per aircraft in the NAS at 35 major airports. As shown in the figure, the average delay per flight will increase from the current 10 to 63 min by the year 2025, almost six times, as demand continues to grow, if the NAS continues to operate as it does today. This will have an unacceptable economic impact on the airlines, which may find it almost impossible to run the operations needed to meet the demand. Consequently, it becomes imperative for government service providers to find ways to enhance airport capacity without compromising on safety.

67.4.5 Measuring Controller Workload

The primary role of a controller is to process a significant amount of information and make timely decisions to maintain safe and efficient flow of traffic. This involves acquiring traffic information by continuously monitoring traffic, perceiving potential separation violation problems, and deciding when and how to resolve these problems. In order to perform these functions, the controllers are involved in a number of tasks: monitoring traffic situations on radar displays, entering data through a keyboard, conducting mental assessment of potential conflicts, communicating with other controllers/facility people, and communicating clearances (routine and conflict resolution) with the pilots. Thus, a human response to these number of tasks is used to measure workload [67.16], which has both physical and mental components. Perceiving and resolving potential aircraft conflicts, especially during heavy traffic, require more cognitive resources than handling other routine tasks.

The workload (mental) primarily depends upon the time interval between detecting a separation violation and dealing with it. The earlier a decision is made to resolve the conflict, the less the workload for a controller. In congested airspace, especially where the aircraft are continually maneuvering (climbing, descending, turning, and changing speed), the controller workload is not only affected by the number of aircraft under control, but also by the impact of their changing geometrics, which creates complexity [67.17]. The complexity not only depends upon the level of peak traffic, but also upon the specific traffic situations, e.g., the number of aircraft on independent, converging or intersecting paths in horizontal and vertical domains. Rightly perceiving problems resulting from complexity requires timely detection and resolution of these problems, in addition to communicating the resolution clearances to the pilots. This often turns out to be a very stressful process that has a major impact on the workload of the controllers.

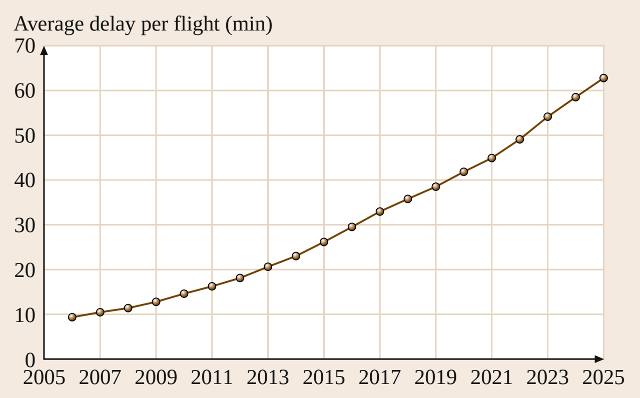

Fig. 67.11 Operational delays impacting flight efficiency

In the future, it is envisioned that automation will accurately detect, resolve, and communicate actions directly to the aircraft over a data link (rather than currently by voice) in order to significantly reduce the controller workload, as traffic continues to grow.

67.5 Future Air Transportation System Requirements and Functional Automation

In November 2005, the European Consortium of Member States signed to define the vision and goals of the Single European Sky ATM research (SESAR), and to develop, validate, and implement SESAR concepts to meet air traffic demand beyond year 2020. The US 108th Congress and the President mandated the design and deployment of an air transportation system to meet the nation's needs in 2025 by passing and signing into law *Vision 100 – Century of Aviation Reauthorization Act* (Public Law 108-176). The transformed air transportation system should be responsive to the social, economic, political, and technological changes, and should meet the future needs for safety, capacity, efficiency, and security. The legislation established a joint planning and development office (JPDO), which is supported by the Department of Transportation (DOT), the FAA, the Department of Defense (DoD), the Department of Commerce (DOC), the National Aeronautics and Space Administration (NASA), the Department of Homeland Security (DHS), and the Office of Science and Technology Policy (OSTP) in the White House. The JPDO published the next-generation (NextGen) air transportation system integrated plan [67.18] defining the objectives for the 2025 air transportation system. The following objectives relate to the specific requirements for safety, capacity, and operational efficiency:

- Maintain the aviation record of safety as the safest mode of transportation
- Improve the level of safety as demand continues to grow
- Enhance airport capacity to satisfy future growth in demand up to three times the current level
- Minimize the impact of weather and other traffic disruptions on NAS operations
- Reduce the transit time from domestic curb-to-curb by 30%.

67.5.1 Automation Approach to Meet Future Air Transportation System Requirements

Increased level of automation in the aircraft and in the ground system will help to meet the above stated requirements for the NextGen air transportation system. In order to improve safety, enhanced aircraft situational awareness in the cockpit and in the ground system will be needed to minimize operational deviations and errors. To maximize capacity and flight efficiency, the future airspace design will have to support each aircraft filing its own desired 4-D flight plans including route, altitudes, and expected times at key waypoints, while the ground automation system will ascertain that these flight plans are conflict free. This would require the ground automation system to accurately estimate aircraft trajectories correlated in space and time, and precisely predict conflicts in order to negotiate any change in their flight plans with the users. Ground-based conflict-free flight planning, with the aircraft adhering to the agreed trajectories, will reduce the need for tactical controller intervention, which would minimize workload. As such, future research should concentrate on developing means to automate the air/ground functions to enhance safety and capacity while reducing flight delays and workload. In order to achieve this, an automation approach is as follows.

Safety

The automation predicts aircraft conflict problems and provides decision support to the controllers in resolving them.

Capacity

No doubt the building of new runways and airports increases airport capacity, but it is a time-consuming process to address the environmental and adjoining community issues required to add new runways to the major airports or build new airports. Although the airports authorities in the US are considering the construction of a few new runways, and a couple of new airports outside Chicago and Las Vegas, the majority of future capacity improvements will have to come from using new technologies and automation by:

- Reducing separation minima, including route widths
- Reducing performance spacing buffers
- Developing automated RNP approaches.

Flight Efficiency and Delays

- Automation supports departure/arrival planning
- For strategic end-to-end flight planning, automation deals with system uncertainties.

Workload

- Automation handles routine ground/air clearances
- Transfer some ground-based decisions to the aircraft with automation assisting aircraft in self-sequencing, merging, and spacing.

67.5.2 Development of Automated Functional Capabilities

Relying on automation decision support and new technologies, the following functional capabilities are going through exploratory research and potential development to meet the above requirements for the future air transportation system.

Automated Problem Resolution to Enhance Safety

As discussed earlier, the URET function in the ground system provides the en route controllers with an automated conflict detection capability, which uses predicted aircraft trajectories to continuously detect potential aircraft separation problems up to 20 min into the future, and accordingly alert the appropriate controllers. This function is being enhanced so that the ground automation provides the controller with solutions or resolutions of aircraft conflicts with other aircraft, segments of airspace, and hazardous weather cells. The MITRE Corp. center for advanced aviation system development (CAASD) is developing such a capability, called problem analysis resolution and ranking (PARR). When the URET detects a conflict, the PARR examines strategic vertical, lateral, and speed change options to resolve these conflicts.

The PARR may be initiated for a specific aircraft with one or more problems, or for a specific problem. In these cases, the PARR examines a variety of resolution dimensions and directions. If initiated for an aircraft, the PARR generates resolutions which maneuver only that aircraft. If initiated for an aircraft-to-aircraft problem, the resolutions for each of the two involved aircraft are generated.

For a given aircraft to be maneuvered, the PARR searches for problem-free trajectories to resolve all problems with that aircraft (within URET's 20 min lookahead horizon) in an operationally acceptable manner, without introducing any new problems. The search process examines, in turn, maneuvers in each of the following five dimensions/directions, thus yielding up to five resolutions for that aircraft:

1. Select an altitude above the altitude of the problem
2. Select an altitude below the altitude of the problem aircraft
3. Turn aircraft left of the route
4. Turn aircraft right of the route
5. Increase or decrease speed.

Each resolution requires only one maneuver [67.19].

The completed PARR resolutions are ranked, color-coded, and displayed on the URET plans display; for example, conflicts predicted with violation of separation minima are coded red. This provides the controllers with information to set priorities in dealing with the problems. After the aircraft follow the resolution maneuvers, and there is no more problem, the aircraft return and continue on their original flight trajectory. The PARR could also generate resolutions around hazardous weather areas.

It is expected that the PARR function will significantly enhance safety. The safety enhancements are important, since the relaxation of ATC restrictions in the future could lead to more complex traffic patterns. The PARR would assist in maintaining or enhancing safety in two ways. First, the PARR provides an automation capability with which the controllers can obtain an improved, strategic situational understanding, e.g., by quickly assessing which altitude, speed, or direct-to-fix alternatives are problem free. Second, the resolutions provided by PARR allow the controller to easily implement strategic, problem-free resolutions, which would allow more time for decision-making and coordination for handling other pilot requests.

Reducing Separation Minima to Enhance Capacity

The airport capacity for a single runway depends upon the weight-class-based wake vortex separations between successive aircraft in-trail on a final approach, the length of the final approach to capture the ILS localizer, runway occupancy times, and a spacing buffer for safety. For operations on parallel runways and routes, the lateral separation depends upon the ability of the aircraft to fly close to their desired path centerline.

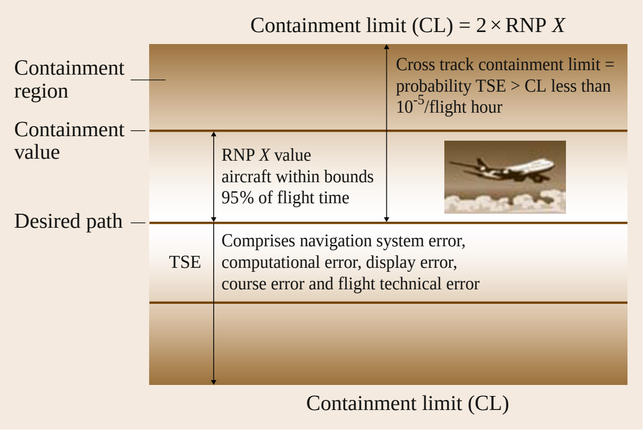
The established IFR separation minima apply during poor visibility (less than 3 nmi) and/or lower cloud cover ceiling (less than 1000 ft). When the visibility and the ceiling are higher than these conditions, the aircraft fly VFR when the pilots are able to see other aircraft and the runway before turning onto the final approach, a situation called, *see and be seen*. For these visual operations, the aircraft are observed to land with much smaller separations than the established IFR separation minima without compromising any safety, but yielding a much higher capacity. This is because the aircraft are not constrained by the required longer ILS straight-in approaches and a fixed glide slope. Therefore, by flying shorter final approaches and variable glide slopes, the aircraft encounter less impact of wake vortices, and as such could use less in-trail separations. The following future avionics technologies will help reduce the current wake vortex separation minima by permitting aircraft to operate as VFR under all weather conditions. The required navigation performance capabilities in the aircraft will support reduction of lateral separations between routes. A future terminal automation function discussed later will reduce spacing buffers by reducing the impact of flight uncertainties.

Aircraft Technologies for Electronic VFR Operations

Although there have been no separation minima established for the current VFR operations, there is sufficient data available to define them, if the aircraft could operate like VFR during IFR conditions. The following technologies will help pilots operate as VFR at night and during poor weather and visibility conditions.

Using ADS-B information from the aircraft in the vicinity of the subject aircraft, the CDTI displays the position of other aircraft on a screen in the cockpit. The head-up display (HUD) is mounted on the aircraft instrument panel below the windshield to monitor the external environment (aircraft and airport). The HUDs provide microwave and infrared (IR) images to the pilots. The use of these wavelengths allows pilots to see the runways in poor visibility by penetrating fog or other adverse weather conditions. The enhanced vision system (EVS) enhances a pilot's situational awareness during approach and landing, when the visibility is poor, using an IR camera displaying a picture of the surface below.

The synthetic vision system (SVS), with its ability to let pilots see terrain, obstacles, and runways in poor visibility conditions, is designed for use by high-end business jets for situational awareness and safety. A 3-D view allows the pilots to see rendering of terrain ahead using information from onboard obstacle, terrain, and



Containment limit (CL) = 2 × RNP X

airport databases and tracked flight path. The navigation display shows the intended aircraft flight path with a view that provides real position over the terrain with respect to the flight plan.

Required Navigation Performance

In order to reduce the requirement for lateral separation between aircraft on parallel routes, or to conduct simultaneous approaches to closely spaced parallel runways, the aircraft would need to have a RNP capability. The RNP enables aircraft not only to fly RNAV point-to-point, but also to stay within certified route containment limits with an onboard monitoring and alerting function. This function enhances the pilot's situational awareness, and alerts the pilot when there is a gross deviation from the route centerline, thereby permitting closer route spacing without ground ATC intervention.

Figure 67.12 shows the RNP concept and the lateral components of the aircraft navigational error. The RNP is a measure of navigation performance accuracy and integrity (i. e., route containment and time to alarm) necessary for aircraft operations within a defined airspace. As shown in the figure, an aircraft certified for a given RNP value, e.g., RNP X, must navigate with a total system error (TSE) not to exceed $2X$ nmi with a probability of 10^{-5} per flight hour, defined as the cross-track containment limit. When exceeding this limit, the monitoring function will generate an alert for the pilot to correct back to the desired course. The RNP X value defines the bound of lateral deviation with a probability of 95% of flight time.

The TSE is the deviation of the aircraft's true position from the desired course or the centerline of the route of the flight path programmed in the FMS. The TSE is a combination of errors from the following contributing factors:

- Navigation system error
- RNAV computation error
- Display system error
- Course error and flight technical error (FTE).

The airborne equipment accounts for data and computational latencies, equipment response time, and navigation sensor error characteristics for its interfaces. The TSE value assumes a flight director or an autopilot operation that allows the use of either GPS or DME/DME as navigation sources for position determination. The aircraft are capable of RNP 0.3 aided by a flight director in the aircraft, and RNP 0.11 with a coupled highly accurate automatic flight control system (AFCS). The en route path lateral separation requirement could be reduced to 4 nmi from the current 8 nmi for aircraft with RNP 1. RNP 0.11 would permit independent parallel runway operations with significantly reduced runway spacing.

Automation Functions to Improve Flight Efficiency and Reduce Delays

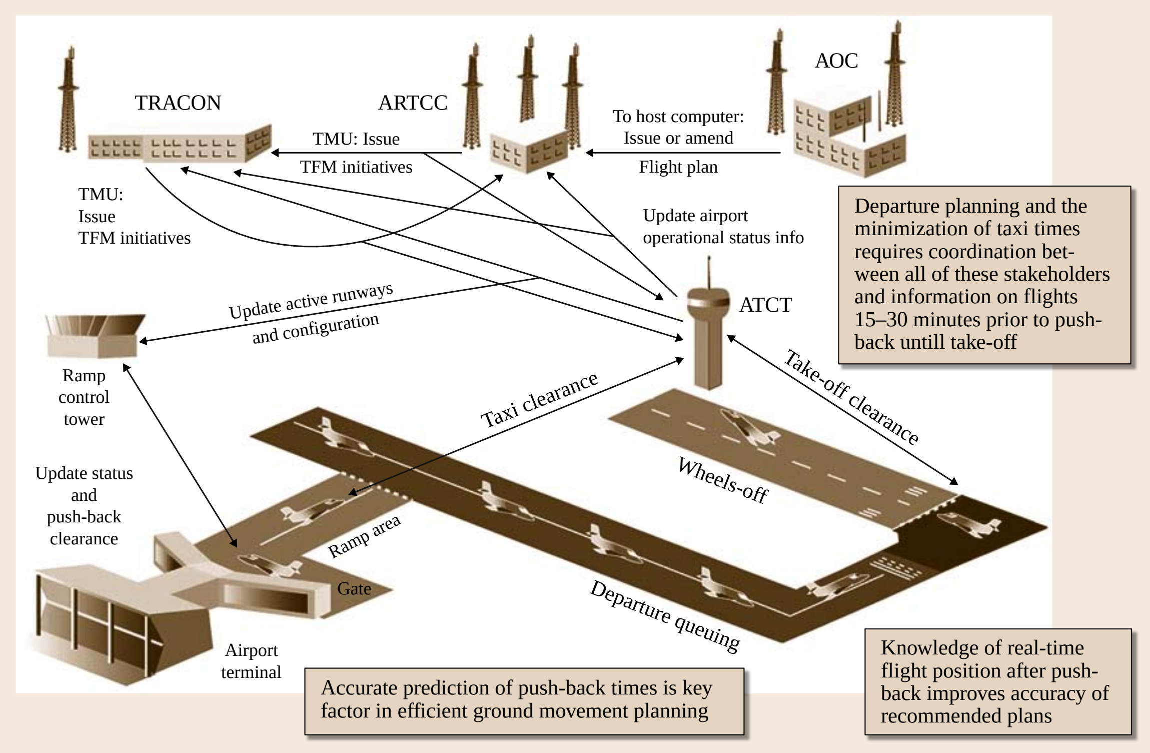
Probabilistic Traffic Congestion Management. The current TFM function balances air traffic demand against airspace constraints and airport capacity taking into consideration the forecasted weather conditions [67.20]. A variety of flow control actions are used to deal with the airport capacity constraints. These include weather avoidance routes, miles in-trail (MIT) restrictions to deal with traffic congestion at fixes and the ground delays generated by the ground delay program to establish expected departure clearance times (EDCT) for flights. Planning for these actions requires predictions of both the traffic demand and the airspace (sector) capacity. Since the TFM decisions are typically made 30 min to several hours in advance of the anticipated congestion, these predictions are subject to significant uncertainty. However, the magnitude of this uncertainty is not known, presented, or understood. As a result, traffic management decisions are often overly conservative, and may be taken at inappropriate times depending upon the accuracy of prediction data. The traffic demand uncertainties arise from many sources. The flight schedules undergo constant changes in response to daily events, and such changes often occur between the time of demand prediction and the time for which demand is predicted. These include flight cancelations, departure time changes, and initiation of previously unscheduled flights. This latter category is increasing in the USA, as air taxi and *executive jet* operations are becoming more prevalent.

Several new techniques and technologies are required to provide probabilistic TFM decision support. First, prediction uncertainty must be known and quantifiable. Second, a metric is needed for rating the goodness of the candidate solutions. Third, decision-making algorithms are needed to develop congestion management solutions, given the prediction uncertainty and the goodness metric. Finally, there are significant human factors issues to be resolved due to the combination of information uncertainty and complex automated processes.

Effective TFM decision making in the presence of uncertainty or *probabilistic TFM*, should have the following characteristics:

1. Rather than attempting to resolve all possible congestion problems, incremental actions are taken to keep traffic congestion risk at an acceptable level, while retaining flexibility to take further actions as the situation becomes more certain
2. Predicted traffic congestion areas are continually reevaluated for further control action
3. NAS users are informed of predicted congestion, so that they can proactively reduce schedule risk if desired (e.g., by replanning flights through less congested airspace)
4. Probabilistic congestion predictions are presented to traffic planners and users in an intuitive way, in order to maintain good situation awareness.

Multicenter Traffic Management Advisor. The TMA function implemented in the en route automation host computer systems (HCS) regulates or meters traffic arriving from different directions within a single ARTCC to a major airport. The development of multicenter traffic management advisor (McTMA) led by NASA is being built upon the TMA hardware and software baseline. The McTMA is an automation decision support function, which extends time-based metering from a single ARTCC/single airport arrival traffic flow planning to multi-ARTCC operations dealing with traffic flow problems at critical bottlenecks in the en route



Departure planning and the minimization of taxi times requires coordination between all of these stakeholders and information on flights 15–30 minutes prior to push-back untill take-off

Accurate prediction of push-back times is key factor in efficient ground movement planning

Knowledge of real-time flight position after push-back improves accuracy of recommended plans

Fig. 67.13 Required coordination during departure process

airspace and merging of departure traffic with overflights. This function employs a distributive scheduling algorithm to develop flexible collaborative metering plans taking into consideration the ATC constraints at airports and in the en route/transition airspace spread across a region comprising a number of ARTCCs. The distributed scheduling provides a dynamic look-ahead capability and a provisional landing slot reservation system to continuously monitor and feedback upstream adjustment of flight times. This is required to deal with demand/capacity imbalance at the point of congestion [67.21].

Departure Planning and the Role of Airport Surface Automation. Most of the traffic flow management constraints are applied at the airports when the traffic demand exceeds either the en route capacity or the capacity at the flights' destination airport. Consequently, these restrictions are imposed on departing flights so that a particular flight departs at a specific time in order to fit into a specific place in the stream of traffic, or to fit into a specific arrival time slot at the destination airport. The management of these departure time constraints can make the airport surface air traffic control task much more complex. A surface automation function is needed to take all of these constraints into account for efficient departure planning. The airport surface automation system will also help reduce airport accidents, although small in number (13 from 1997 to 2007), by providing timely and accurate information on aircraft positions both to the ground system and the cockpit.

Figure 67.13 illustrates the exchange of information between the various facilities to manage departing flights in order to use capacity at major airports effectively. The airport ramp control tower provides each aircraft with a clearance to push back from the gate. The desired airport runway configuration to use is given by the tower, so that each departing flight could exit the ramp at an appropriate time. The ATCT is responsible for providing clearances for the aircraft to taxi safely from the ramp area to the departure runway, and to take off at appropriate times so as to meet all traffic flow constraints and safe separation requirements. The TRACON provides the ATCT with the relevant traffic flow constraints upstream, as does the ARTCC. The AOC provides the initial flight plan and manages the dispatch of each flight under its control.

The airport departure capacity is a function of the sequencing of flights to each departure runway. Aircraft in the heavy weight class require more spacing behind them than smaller aircraft. Therefore, clustering heavy aircraft together could significantly increase runway capacity. Dynamically managing arrivals and departures, by building extra arrival runway slots when necessary to absorb extra arrival demand, also improves the overall effective use of airport capacity.

In order to facilitate all of the above interrelated decisions, the airport surface automation system should provide the following four functions, and the information generated must be provided in real time to all of the decision-makers shown in Fig. 67.13:

- Surface aircraft and vehicle surveillance
- Automated transfer of controller clearance and flight intent information
- Detection of potential airport surface conflicts
- Automation decision support function to assist the ramp control tower and the ATCT to best use the available runway and taxiway capacity.

Surface aircraft and vehicle surveillance, as well as the automated clearance and intent information transfer, are the two key functions that enable the other two functions listed above. Information about the current position of each aircraft and the vehicle located on an airport's taxiways and runways, integrated with the positions of the aircraft immediately around the airport, provide the ATCT and the ramp control tower with the ability to see all of these objects, even when the physical line of sight is obstructed by low airport visibility conditions (fog). They also provide the necessary input to the surface conflict detection function, which uses the known positions of each aircraft and vehicle and infers the future path of each aircraft and vehicle (e.g., the cleared taxi path), in order to detect potential conflicts. When a conflict is predicted, the automation function generates an alarm for the controller to alert the pilot to take an action to avoid the conflict.

The surface automation decision support function provides the traffic flow managers and the air traffic controllers in the ATCT and the ramp control tower with recommendations on actions such as:

- When to change the runway configuration to minimize the loss of capacity during the changeover
- In what order to best maximize the taxiing aircraft movement through the exit spots at the edge of the ramp area
- In what order to best queue aircraft to maximize runway capacity given the traffic constraints, the size of the aircraft, and other factors
- How best to introduce arrival slots between the departure slots to minimize arrival and departure delays.

The approaches to develop these automated decision support functions have already been discussed in detail [67.22, 23].

Terminal Automation for Arrival Planning and Control [67.24]. Over the years, two terminal automation functions, viz. metering and spacing (M&S) and the final approach spacing tool (FAST), were developed and went through extensive validation and field testing. However, these functions were not accepted by controllers, because the automation-generated information was either too constraining or inconsistent with the human decision process. These functions were intended to complement en route metering function (TMA) to accurately establish landing sequences and times to enhance airport capacity. The crux of the problem was a discrepancy between the TMA-planned nominal flight trajectories and the actual trajectories flown by aircraft tactically changed by TRACON controllers to achieve desired separations between aircraft.

The TMA establishes desired meter fix times for the traffic going to an airport while they are still in the en route airspace by establishing landing sequences and times based on prestored aircraft trajectory data and wind information over the terminal airspace. The en route controllers try to meet these meter fix times within a specified tolerance (1 min) by maneuvering the aircraft before they reach the meter fixes. Once the aircraft enter the terminal airspace, the terminal controllers merge traffic generally coming from four different directions to maintain the required separations, as well as guide the unequipped aircraft in the terminal maneuvering areas, if there are no navaids. As such, they end up changing the en route metering system planned paths and landing time schedules. This affects the flight planning and operational efficiency for aircraft all the way to touchdown by first getting delayed in the en route airspace and then getting further delayed in the terminal area.

A terminal automation arrival planning and control function is needed to complement the en route planning function in order to predict arrival schedules accurately. This is essential for realizing maximum efficiency benefits for the users by flying optimum paths, and for the service providers to manage diverse aircraft traffic with minimum air–ground communications. This function should minimize the variations between the aircraft flight planning and actual operations by first defining routes all the way to touchdown and then establishing landing sequences and schedules using accurate flight time estimates.

The basic requirement for establishing an efficient terminal area flight plan for each aircraft is that it should be based on minimum flying time from the entry (meter) fix to the runway. In order to achieve the earliest permissible landing times:

1. The plans should be based on the shortest paths
2. Continuous descent from meter fixes to touchdown
3. The aircraft are assumed to fly highest permissible speeds over each flight segment
4. The routes from different directions towards final approach (s) are adequately separated to avoid conflicts during merging of traffic
5. The landing times for successive aircraft ensure adequate separations based on wake vortex considerations.

Once the landing times are established, they should be integrated with the en route planning of flight times such that, when the aircraft arrive at the meter fixes within a desired tolerance, they should be able to continue on the established 3-D profiles without any need for path deviations to maintain separations. The en route metering process ensures delivery of aircraft at the meter fixes within the expected time variance.

In most major terminal areas today, the aircraft, using four-corner post configuration, navigate over established STARs from the meter fixes to about 10–15 nmi radial distance from the airport. Depending upon the direction of arrival, the aircraft either fly a downwind path and then turn onto a base leg, or turn directly onto the base leg, before intercepting the final approach as shown in Fig. 67.14. Since there are mostly no established routes in the base-leg region, the

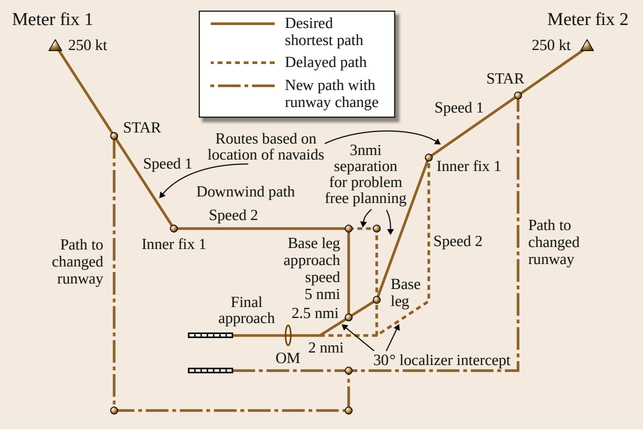


Fig. 67.14 Terminal merge-free route design for flight planning, with permission from IEEE

controllers merge the traffic coming from the opposite directions over the two base legs, and then again merge the traffic flying over the two base legs from the opposite directions onto the final approach to a single runway. Merging of aircraft at two or three points, while keeping them separated, results in inefficient, large path deviations and significant workload for both the pilots and the controllers.

In order for most of the aircraft to stay on the minimum path for maximum flight efficiency with short delays, aircraft-derived speed control should be used as the primary means to compensate for aircraft performance deviations and wind forecast uncertainties. In order to achieve this, the terminal route design should eliminate the need for the controllers to merge traffic at multiple points except on the final approach(es). As such, the routes should not only be the shortest, but all merge points should also be eliminated. As shown in Fig. 67.14, the aircraft arriving from the direction opposite to the direction of landing (meter fix 1) fly a downwind path from the end of the STAR turning onto a base leg 5 nmi long before intercepting the localizer course. For smooth capture of the localizer, the aircraft intercept the final approach course at an angle of 30° or less over a path segment of 2.5 nmi to allow for smooth turns from the base leg to the localizer course. The aircraft also need to capture the localizer for final approach course about 2 nmi from the outer marker in order to be stabilized over the glide slope to the runway. This defines the minimum path in the base-leg region. The aircraft arriving from the other direction (meter fix 2) turn directly onto the base leg before capturing the localizer course. In order to create a merge-free route design, the base legs are separated by 6 nmi to keep the aircraft not only safely separated when arriving from different directions, but also to allow for some margin of airspace to deal with pop-up aircraft, missed approaches or large aircraft deviations (as shown dotted in the figure). A mirror image of the design in Fig. 67.14 could be applied to the other two fixes, either to the same runway or to a parallel runway. The figure also shows a path in case the runway assignment is changed. In the future, if some other than ILS precision landing guidance is available, the base-leg and final approach paths could be shortened for curved approaches customized for each aircraft depending upon its avionics capabilities.

After entering the terminal area, most aircraft are required to reduce speed to 250 kt before they attain an altitude of 10 000 ft. From there on, depending upon the aircraft performance characteristics, the aircraft typically go through two speed reductions (speed 1 and speed 2 in Fig. 67.14) before reducing to their final approach speeds. The automation function could determine timing or location of these speed reductions to compensate for flight time variances from the desired landing times without requiring the aircraft to divert from the above-defined minimum paths.

The NextGen concept for the future air transportation system considers 4-D navigation as one of its core elements. In order for the aircraft to operate in a 4-D-navigation mode, a 3-D flight profile is established from take-off to landing with estimated times of arrival at key decision points along the path. The aircraft are required to stay on the predefined 3-D paths and meet the times at these points by adjusting speeds along the flight segments using the onboard required time of arrival (RTA) function with automated thrust management. Because of the time compression at the end of flight during the arrival/landing phase, any path deviation along the way would be counter to the goals of 4-D navigation.

Air/Ground Automation with Aircraft Self-Separation to Reduce Workload

Air traffic controllers today are involved in a number of routine ground–air communications, such as changing frequency, when the aircraft transition from one controller airspace to another's. In the future, the ground automation system will directly communicate routine information over a data link to the aircraft FMS. In addition, the primary responsibility of the controller to separate aircraft could be shared with the appropriately equipped aircraft, which could self-separate under certain situations as discussed below. The increased use of automation both in the ground system and in the aircraft cockpit will help reduce workload for both the controllers and the pilots.

Before aircraft are committed to the final approach, the controllers direct the aircraft to maintain specific in-trail spacing when following each other, or when the aircraft merge from different directions on a common point in airspace, and then follow each other in a single stream of traffic. This process requires a series of clearances, as well as monitoring of aircraft conformance to the directions from the ground. This is workload intensive for both the pilots and the controllers. In the future, with the aircraft equipped with ADS-B, CDTI, FMS, and RNP, including a monitoring and alerting capability, the aircraft will have the ability to maintain separation from other equipped aircraft. Flight-deck-based merging and spacing concepts are being explored in which a strategic setup is established by the ground system followed by cockpit-based self-separation [67.25].

NASA has defined an automated airspace concept that uses ground-based automated airspace computer system (AACS) to generate conflict-free air traffic control advisories and send trajectories via a two-way data link to the FMS of equipped aircraft. With traffic situational awareness provided by CDTI, the pilots could assume separation assurance responsibility during certain traffic conditions. Although the selection of data link and data transmission protocols to meet these requirements is uncertain at this time, mode S, ADS-B, and VDL2 are likely candidates for this concept. The automation of separation assurance function will also mitigate a number of ATC constraints that limit the efficiency and capacity of the current ATM system [67.26].

The joint FAA/Eurocontrol Cooperative Research and Development Committee defined the principles of operation for the use of airborne separation assurance systems (ASAS) taking into account US and European perspectives for global applications [67.27]. The primary guiding principle is based on cooperative involvement of both the pilots/aircraft systems and the controllers/ATM system in assuring separation among aircraft. Four specific ASAS applications defined are:

1. Airborne traffic situational awareness to enhance pilots' knowledge of surrounding traffic
2. Airborne spacing to permit pilots to maintain a given spacing with designated aircraft
3. Airborne separation when the controller delegates separation assurance responsibility to the pilots
4. Airborne self-separation when the pilots achieve separation from other aircraft in accordance with the desired separation standards and rules of flight.

These concepts make use of aircraft capabilities-based performance to establish different control mechanisms for different segments of airspace. The equipped aircraft assume responsibility for self-separation and for monitoring and alerting in most airspace, except where there are high-density traffic operations. Most FMS using GPS for navigation alert the pilots when navigation performance exceeds RNP criteria. This *UNABLE RNP* alert is based on probability and not on measured error, and is only a part of the required monitoring and alerting process. A flight technical error relative to the computed path is displayed to the pilot for monitoring lateral and vertical deviations. A corrective action is required if either the lateral or vertical deviation exceeds the lateral RNP limit, or 75 ft in vertical, respectively. The GPS meets the monitoring and alerting requirements of accuracy and integrity through RAIM alerts tied to the RNP value for each phase of flight. This means that the separation assurance responsibility is ground based in the airspace where the traffic density and flight uncertainties are high, whereas some separation assurance responsibility could be delegated on a pairwise basis to aircraft during light traffic. In other airspace segments, both the aircraft and the ground automation share responsibilities, with the aircraft responsible for tactical flow management and separation assurance, while the ground system is responsible for strategic traffic flow management.

67.6 Summary

The current US air transportation system has an excellent record for safety of aircraft flying in accordance with the IFR separation requirements. The NAS relies on VHF for voice communication between the pilots and the air traffic controllers, ground-based VOR/DME systems for navigation, primary and secondary radars for surveillance, and ground-based automation for flight and radar data processing at local, regional, and national ATC facilities. During 2006, over 700 million passengers flew in the NAS, and the cargo revenue ton miles exceeded 40 billion. The NAS manages about 55 000 operations daily, with about 6500 flights in the air during peak demand. The density of traffic is creating congestion at airways and airports, thereby creating bottlenecks resulting in flight delays, which cost the airlines millions of dollars in lost revenue.

With the demand for air traffic services continuing to increase, future delays will increase significantly unless the NAS is transformed. Satellite-based CNS technologies offer the opportunities to enhance safety, airport capacity, and flight efficiency. The new generation of aircraft has already acquired avionics compatible with satellite-based CNS technologies, with increased automation provided by the FMS. However, the ground system infrastructure needs to be modernized using satellite-based CNS technologies and automation of decision support functions.

This chapter describes the current CNS and ATM infrastructure, which includes VHF/HF communications, ground-based navigation systems, viz. VOR, DME and ILS, and primary/secondary radars for surveillance. Upcoming satellite-based CNS technologies are also discussed, e.g., VHF data link for data communication, GPS/WAAS for navigation, and ADS-B for surveillance. How these technologies will enhance aircraft operations with direct air/ground communications, RNAV point-to-point navigation, and improved aircraft tracking for automated decision support is elaborated in order to provide an understanding of the major technological transformation expected in future NAS.

The functional role of automation in the aircraft and the ground system is addressed in terms of their limited use today, as most of the decisions in the cockpit and on the ground are human-centric. The two major functions of the ATM system in NAS, viz. TFM and ATC, and their limitations are addressed. Most of the automation functions such as MSAW/conflict alert/URET are primarily used for aircraft safety. Limited automation functional capabilities exist, such as TMA and ETMS, to deal with capacity, flight efficiency, and workload, although a number of newer aircraft have FMS to help aircraft fly efficiently.

The metrics to measure CNS/ATM systems' performance are aircraft safety, airport capacity, flight efficiency with its impact on delays, and pilot/controller workload. The established government regulations require the aircraft to follow other aircraft with specific separation distance minima in various phases of flight. Because of human decision making, the controllers often plan for larger than the required IFR separation distance rules to ensure safety, although this adversely affects capacity, resulting in increased delays and workload. A detailed explanation of the factors used in defining the above performance measures is provided here to develop a clear understanding of the CNS/ATM system operational elements that the new technologies should improve, and the functions which should be automated for the air transportation system of the future.

This chapter also provides highlights of the future CNS/ATM capabilities for the NextGen system for the year 2025 and beyond, with its goals and objectives. How the enhanced automation could meet the requirements of the future system for increased safety and capacity, as well as for reducing delays and workload, is also discussed.

In order to realize some of the goals of the future air transportation system, research is going on to develop new capabilities such as RNP, CDTI, and EVS in the cockpit, and automated functions such as PARR, McTMA, probabilistic TFM, and automated departure/arrival management for the ground-based ATM system. The new aircraft technologies will provide the aircraft with an ability to operate in poor-visibility conditions just like they operate in good-visibility conditions to reduce separation minima and increase capacity. The enhanced automation in the cockpit and in the ground system will be better able to deal with the system uncertainties to improve flight efficiency and reduce delays, as well as provide both the pilots and the controllers with accurate and timely decisions to help reduce their workloads. Moreover, some sharing of separation assurance responsibility between the pilots and controllers would result in equitable distribution of workload for ensuring safety of flights.

Because of the limited space here to cover the vast scope of the current air transportation system functions and capabilities and ongoing research to develop the future system, this chapter provides a tutorial at a high level. For specific details of any feature of the current or future systems, it is recommended that the readers seek information on the US FAA or the ICAO websites (www.faa.gov or www.icao.int), respectively.

68. Flight Deck Automation

Steven J. Landry

A review of flight deck automation is provided with an emphasis on examples and design principles. First, a review of historical developments in flight deck automation is provided. Current examples of control automation, warning and alerting systems, and information automation are then provided. A discussion of human factors, integration, safety, and certification issues are then discussed. The chapter provides guidance to managers, engineers, and researchers tasked with studying or building flight deck systems. In particular, the chapter provides an appreciation of the challenges of building such systems, and the challenges facing those who will build the flight decks of the future.

68.1 Background and Theory

Both the USA and European countries are currently researching and developing automation, procedures, and concepts in order to transform their respective air-traffic systems [68.1, 2]. This transformation will significantly affect aircraft flight decks for many decades. As the shape of this next-generation air-traffic system develops, sophisticated automation will be needed to take advantage of the new infrastructure. This need poses many challenges, including: how to take advantage of a likely massive increase in the amount of available information, how to increase automation in a complex human-integrated system without reducing safety, and how to ensure that collisions between aircraft do not occur in the face of significantly increased density.

This chapter is designed to provide guidance to engineers and researchers who will develop technologies for new flight decks. These engineers and researchers will need to understand the challenges of developing automation for a flight deck, including technological, regulatory and certification, and human factors issues. As will be discussed, much has been accomplished from the early days of automation. There have been significant technological advances (such as satellite digital communications), but the utilization of these technologies in flight decks has been relatively slow. Regulatory agencies are conservative in approving the introduction of unproven technologies, and there are many integration issues associated with bringing new automation into complex socio-technical systems such as aviation.

First, a brief review of historical developments in flight deck automation is provided. Next, several specific types of automation are discussed: control automation, warning and alerting systems, and information automation. This is followed by a discussion of guidelines for flight deck automation development. This discussion centers on human factors issues, system integration issues, safety, and certification. Lastly, several emerging concepts that appear to be the most critical for the US and European efforts are discussed.

68.1.1 Historical Developments and Principles

The very earliest flight decks had no automation per se, and only rudimentary instruments to monitor the engine, magnetic heading, and orientation (with respect to the horizon). Later additions included barometric altimeters to indicate altitude, airspeed indicators (for the prevention of stalls), and sideslip indicators. It was not until flight at night and in conditions of poor visibility was needed in the 1930s that more sophisticated navigation instrumentation became available.

Quite likely the first piece of significant aircraft automation, however, was introduced in 1914 by Lawrence Sperry. Sperry, utilizing the concept of the gyrocompass invented by Hermann Anschütz-Kaempfe (and subsequently patented by Sperry's father in the USA), developed a gyroscopic stabilizer for an aircraft, and attached it to the control surfaces of a Curtiss B-2 biplane. In a demonstration in France, Curtiss and his mechanic (Emil Cachin) climbed out on the wings as the now-pilotless plane passed in front of crowds of spectators, thereby demonstrating the first autopilot [68.3].

Sperry's autopilot used the principle that a spinning gyroscope has a strong tendency to maintain its orientation regardless of the orientation of the containing body. Therefore, deviations of the orientation of an aircraft from the neutral positions (as given by the axis of the spinning gyroscope) can be determined. This signal can then be used to drive the control surfaces of the aircraft according to specific control laws (which will be discussed later in the chapter). Sperry was able to package this in a device that measured 18 in × 18 in × 12 in, and weighed only 40 lb (whereas his father's gyrocompass was so large it could only be used on large warships) [68.4].

Sperry's invention was the first of what will be called *control automation*, whose purpose is to replace human control of the aircraft with machine control. If, in considering automation, only mechanical systems that replace human functions are considered, then there are roughly two other categories of automation in aircraft – warning and alerting systems and information automation, although many systems straddle these classifications.

Warning and alerting systems replace the pilot's function of manually monitoring for hazardous conditions. For example, airspeed indicators were developed mainly so that pilots could ensure that they maintained sufficient airspeed to prevent a stall, which is a hazardous condition where the wings no longer produce enough lift to counteract the weight of the aircraft (which therefore begins to fall). In most modern aircraft, this monitoring function is replaced by a stall warning device, which alerts the pilot to an impending stall without the pilot having to monitor airspeed and compare it with a memorized stall speed.

The first warning and alerting systems automation was likely an *off* flag for a particular instrument, warning of that instrument's failure. Warning and alerting systems proliferated rapidly starting in the 1960s and 1970s, with the Boeing 707 (rolled out in 1954) originally having only a few simple warning devices (such as engine fire warning systems), the Boeing 747 (deployed in 1969) having few (if any) more (although many have been added to it over its life), and the Boeing 777 (whose maiden flight was in 1994) being the first built with numerous warning systems as standard equipment.

Information automation provides pilots with access to information that they would otherwise have to locate manually or calculate themselves. For example, pilots will follow written checklists for various portions of flight, and have procedures to ensure that checklist items are completed. In some aircraft, checklists are presented in electronic format, with the system ensuring that checklist items are completed.

Probably the first information automation introduced was the flight director. This automation provided intercept guidance for pilots, who previously would have had to determine appropriate intercept angles for a desired course (and glideslope – the desired descent angle to the runway).

World War II saw a dramatic increase in the use and sophistication of aircraft, with that trend continuing through the present day. In the early 1950s, a blue ribbon panel was convened by the US government to study research needs in aviation. This panel was chaired by Dr. Paul Fitts, who was one of the pioneers of applying engineering and psychology together to improve aviation safety. The Fitts report provides a convenient milepost for the state of automation and automation research at the time [68.5].

68.1.2 Modern Automation

Modern flight decks include a great deal of automation of all three types (control, warning, and information) mentioned previously, although this is highly dependent on the type of aircraft. At the top of the sophistication ladder (for civilian aircraft) is the modern airliner, while there are still aircraft flying today that have the same level of sophistication and instrumentation as the earliest aircraft.

The most sophisticated commercial aircraft have three-axis autopilots that are driven by a combination of inputs from a gyroscopic inertial navigation system, global positioning system, and flight management system into which is loaded the desired flight route in three (sometimes four) dimensions. These autopilots can navigate to any point on the globe, and can be programmed to arrive at a precise time. Moreover, these autopilots have the capability to control the airplane without human intervention from the time it is driven onto the departing runway by the pilot until it reaches a point just off the arriving runway in any weather conditions.

These aircraft also have numerous alerting and warning systems, including systems that detect collision dangers (with other aircraft and with the ground), unsafe configurations (such as gear not extended for landing), control surface overspeed warnings, engine fire warnings, wind shear alerts, alerts for deviations from assigned/desired altitude, and others. These systems, which usually utilize relatively simple sensors, often contain complex algorithms. Aircraft manufacturer and company procedures dictate specific responses to these alerts.

Modern airliners also contain a great deal of information automation as well. Among the information automation commonly found in today's commercial aircraft are weather and ground-proximity radar, navigation displays, electronic messaging capability utilizing communications satellites, and engine indicating and crew alerting systems (EICAS) displays. EICAS displays are a highly integrated set of displays covering a great deal of different information, including engine temperature, engine pressure, oil temperature, electrical system status, pressurization system status, hydraulic system status, and fuel system status.

In the next section, examples of these applications will be discussed. This will be followed by a discussion of guidelines for automation development, specifically human factors issues, system integration issues, safety principles, and certification and equipage issues. Following that is a discussion of principles for automation development.

68.2 Application Examples

Many examples of flight deck automation were mentioned in the previous section. In this section, specific examples of control automation (autopilots, envelope protection automation, and automation for uninhabited aerial vehicles), warning and alerting systems (system monitoring, hazard monitoring, and collision avoidance), and information automation (automated checklists, cockpit display of traffic information, and data communications) are discussed in more detail.

68.2.1 Control Automation

Aircraft are controlled through manipulation of three rotational axes, as shown in Fig. 68.1, along with control of the thrust produced by the engines. Each of the control surfaces used to manipulate the rotational axes utilizes the same principle as wings – increasing camber of a surface moving through a fluid (i. e., the atmosphere) results in pressure differences between the upper and lower control surfaces. These pressure differences produce a force that tries to move the surface in the direction of lower pressure.

Control surfaces are connected by mechanical, electrical or hydraulic means to controls that can be operated manually by the pilots. The control surface for pitch is the elevator, typically located on the horizontal stabilizer near the tail of the aircraft. Manually, the elevator is controlled by pulling or pushing the control yoke (or joystick). The control surfaces for roll are ailerons, located near the end of each wing. Ailerons are controlled by turning the yoke (or moving the joystick to the left or right). Yaw is controlled by the rudder, which is located on the vertical stabilizer, again near the tail. The rudder is operated by stepping on pedals located near the pilots' feet. Throttles control the thrust of each engine.

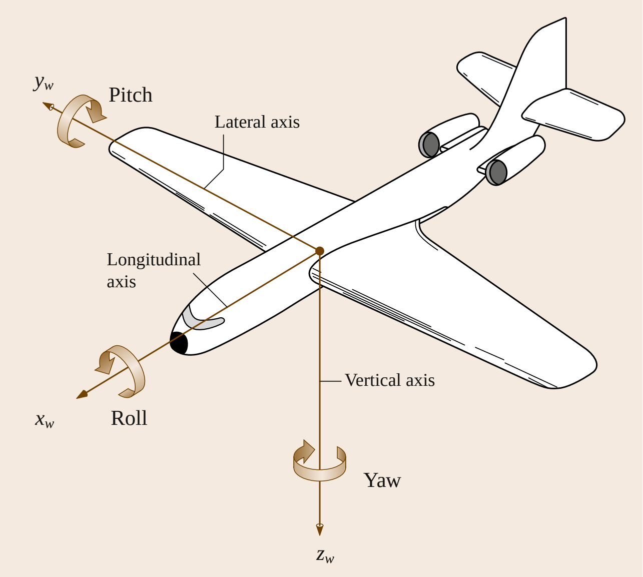

Fig. 68.1 Yaw, pitch, and roll axes (after [68.6])

These axes are somewhat independent, although not entirely. For example, stepping on the rudder pedals introduces yaw, which in turn produces a rolling moment. Increasing power through the use of the throttles results in a pitch change; if pitch is held constant an increase in power results in an increase in speed.

The null setting of each of the control surfaces is set through the use of *trim*, which is operated electrically (or sometimes hydraulically). Trim, however, can also be used to manipulate the control surfaces instead of moving the ailerons, rudder or elevator directly. In some cases trim is a smaller version of the related control surface (for example, typically the ailerons have small tabs which can be moved independently of the ailerons and act as the trim control surface). In other cases, the null position of the entire control surface is set by the trim (for example, typically the elevator null position is set by trim).

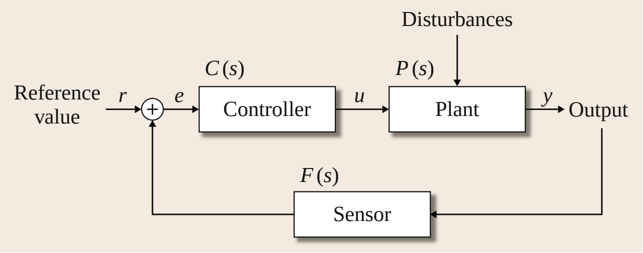

Fig. 68.2 Basic feedback control loop

Autopilots

Modern-day autopilots control all three rotational axes of an aircraft (pitch, roll, and yaw), as well as the thrust. They accomplish this through mechanical, hydraulic or electrical linkages with the trim surfaces and with the throttles. This type of control provides smoother, more accurate positioning of the control surfaces than through cable linkages, although manual movement of the controls can produce larger movements in a shorter period.

The input to autopilots can be thought of as a deviation from a desired rotational angle or speed, although this may have to be derived from a desired ground track, altitude, speed, vertical speed (i. e., rate of descent or climb), bearing from a navigation aid or other form of information more directly applicable to navigation. The specific methods by which error signals are translated into control movements are proprietary secrets of autopilot and aircraft manufacturers, so only a generalized description is given here.

In basic control theory, an input (such as error from a reference) can be transformed into an output through a transfer function, which is commonly specified as a function of the frequency of the signal. Such a system is shown in Fig. 68.2, where the transfer function $H(s)$ is given by (68.1) if plant disturbances are ignored

$$Y(s) = \left(\frac{P(s)C(s)}{1 + F(s)P(s)C(s)}\right) r = H(s)r \,. \qquad (68.1)$$

A simple controller can be constructed using a simple integrator and delay. For such a controller, the transfer function would be given by (68.2), where the time delay is given by τ, the gain is given by k, and the integrator is represented by the s in the denominator

$$H(s) = \frac{k\mathrm{e}^{-\tau s}}{s} \,. \qquad (68.2)$$

In such a controller, the behavior of the system would be to dampen out the error signal, as shown in Fig. 68.3. In such a controller, the error signal from (t – delay) seconds ago is used, resulting in some delay in the response of the controller. That delay leads to the overshoot shown where the error crosses zero just after 0.5 s. The error is fully damped after 3.25 s.

Modern autopilots use very sophisticated algorithms in place of the simple transfer function shown in (68.2). Generally, automatic control in aircraft is considered a multilevel system, consisting of a guidance loop, a control loop, and a stability augmentation loop. The guidance loop controls the navigation of the aircraft by initiating commanded state changes in particular sequences to achieve a navigation goal. The control loop

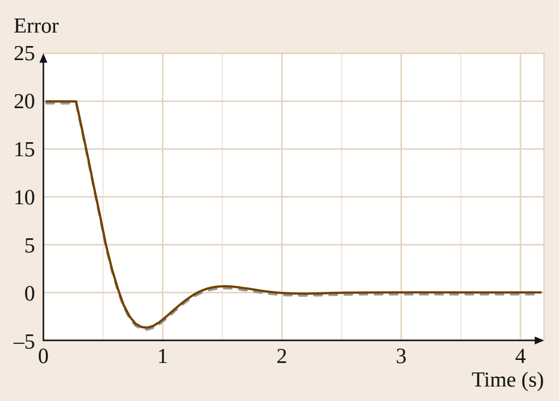

Fig. 68.3 Step response of simple integrator with delay (gain = 3, delay = 0.2 s)

ensures that the commanded states are adhered to by initiating control movements to dampen out errors between the actual and commanded states. Most aircraft also have a stability augmentation loop that dampens out undesirable aircraft modes. One such mode is *Dutch roll*, which is a tendency for aircraft to slightly yaw and roll out of phase continuously in flight.

Autopilot types are categorized in terms of the conditions under which they can be used for approach and landing. Specifically, the categories shown in Table 68.1 can be used to classify autopilots.

Pilots control the autopilot mode of operation through a *mode control panel* (MCP), such as the one shown in Fig. 68.4. Using this panel, pilots select which axes the autopilot should control, and the form of control that the autopilot should use. This form of control is set as the *mode* of the autopilot. Modes that control the pitch axis usually include *attitude hold*, *altitude hold*, *vertical speed*, and *descent angle*. Modes that control the horizontal axis include *control-wheel steering*, *heading hold*, and *course hold*. Autopilots also generally have *airspeed hold*, *mach hold*, and specialized approach modes such as *glideslope capture* and *autoland*.

The typical autopilot has several dozen independent modes, each having complex dependencies with other modes. Some modes are incompatible, and the system must be designed to prevent these from being simultaneously selected. There are also combined modes, where the autopilot will transition into a second mode at some point as programmed into the automation.

The autopilot can be controlled manually by the pilot through the mode control panel, or can be set through the flight management computer (FMC). The desired horizontal trajectory (a sequence of latitudes and longitudes) of the aircraft can be stored in the FMC, which then automatically controls the appropriate modes of the autopilot. The vertical profile as well as times to cross positions or altitudes can also be entered.

These complexities make operating the autopilot and understanding its operation difficult. In fact, several fatal aircraft accidents have been attributed to autopilot *mode confusion*, which will be discussed later in the chapter.

Autopilots, as automation that literally controls the aircraft, is safety critical, and therefore faces rigorous scrutiny before being certified by the national aviation

Table 68.1 Aircraft autopilot categories and weather requirements

Category	Approach and landing weather minimums required
I	60 m/200 ft ceiling 800 m/0.5 statute mile visibility 550 m/1800 ft runway visual range
II (usually with autoland)	30 m/100 ft ceiling 350 m/1200 ft runway visual range
IIIa (usually with autoland)	200 m/700 ft runway visual range
IIIb (IIIa with auto-rollout)	50 m/150 ft runway visual range
IIIc (IIIb with auto-taxi)	0 ft runway visual range

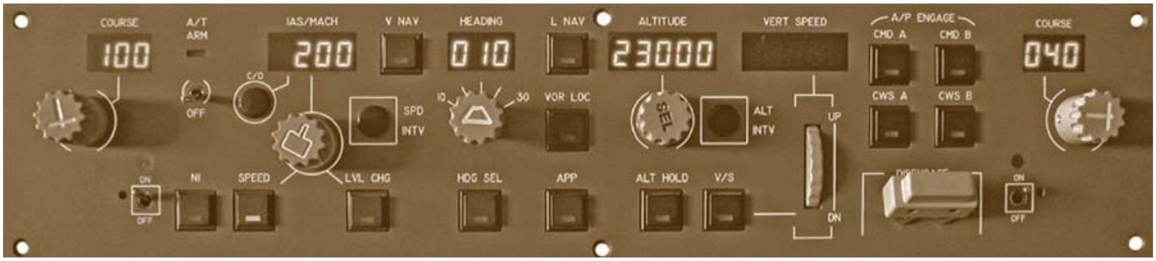

Fig. 68.4 Mode control panel (after [68.7])

authorities. For this reason, developers of autopilot software tend to reuse or add onto existing certified code, or have it generated automatically by systems that can mathematically verify the code.

Envelope Protection

Airbus aircraft have a significantly different automation design philosophy than Boeing aircraft (or many other aircraft manufacturers). While Boeing believes that automation should never be allowed to irreversibly override the pilot, Airbus believes that automation should protect the aircrew from entering unsafe flight regimes [68.8, 9].

This results in automatic envelope protection in Airbus aircraft. Short of deactivating the system, envelope protection makes it virtually impossible to exceed the design limitations (G-forces, maximum speeds) or enter unsafe flight regimes (stalls, excessive angle of attack – the angle of the aircraft to the relative wind). Since Airbus aircraft use fly-by-wire (the control yoke activates the flight surfaces through an electrical signal rather than mechanical or hydraulic linkages), the envelope protection automation can intercept these signals and, for example, reject control inputs that would result in excessive accelerative forces on the airframe.

However, the transitions in and out of flight modes that activate or deactivate certain envelope protections are opaque. This results in additional potential for mode confusion, and has been cited as a causal factor in several accidents [68.10, 11]. There is also the possibility that the aircraft is put into situations unforeseen by the designers.

Both of these situations occurred on an Airbus A-300 flight into Nagoya, Japan in 1994 [68.12]. The aircraft was on approach (being flown manually) when it was inadvertently switched into a *go-around* mode. When the autopilot was activated, it attempted to abandon the approach by climbing and accelerating. However, the pilots, not knowing the aircraft was in this mode, attempted to continue the approach by pushing forward on the control yoke, commanding a pitch down. The autopilot, utilizing the pitch trim, counteracted these commands by running the pitch trim to the full-up limit. As the plane pitched up from the autopilot pitch command, the pilots disconnected the autopilot, but engaged the autothrottles. In response to reaching the maximum angle of attack, flight envelope protection engaged, initiating full thrust, causing the plane to pitch up an additional amount and stall. The pilots were unable to recover from the stall in time and the aircraft crashed, killing 264.

This is not to say that the Airbus philosophy is inferior; records are not kept of how many accidents were *prevented* by having flight envelope protection. Rather, the Airbus philosophy has introduced a new type of error, perhaps trading this off against the possibility of other types of human error.

Although Boeing aircraft do not have strict flight envelope protection, there is a soft envelope protection on its fly-by-wire aircraft. In this form, the system warns the pilot of an approaching limit by increasing the amount of force required to move the control.

Uninhabited Aerial Vehicles

Uninhabited aerial vehicles (UAVs) represent a new class of aircraft, and UAV use is expected to increase significantly in the future. UAVs can range from a sophisticated remote control vehicle (with virtually no onboard automation) to a fully autonomous vehicle with onboard intelligence for navigation and other functions.

Unless one includes guided weapons, UAVs are not fully autonomous. Humans must, at least, provide the system with goals and rules for conduct. In most systems, humans are also involved in monitoring and some aspect of the control loop. Control of the vehicle may be only at the outermost loop (navigation commands), at one of the inner loops (guidance or control) or some combination. For example, the US military's Predator drone requires manual flight for takeoff and landing, but can follow a programmed set of waypoints autonomously. The Global Hawk UAV, however, can takeoff, fly a programmed route, and land autonomously.

UAVs are in extensive use within the military, although their use appears to have been slowed somewhat by development problems and high accident rates [68.13]. Some of these problems relate to the young age of the technology, but some also involves human error. The operation of a UAV is not unlike the operation of a motionless flight simulator, where vestibular and somatosensory cues are absent. The absence of these cues makes fine control difficult, such as required when landing a UAV on an aircraft carrier. Since replacing these sensory cues seems nearly impossible, the emphasis has been on providing more autonomy to the vehicle.

One of the main challenges for incorporation of UAVs into the airspace system is that systems may not be able to deal adequately with a malfunction and still ensure separation from other aircraft. For example, in the case of a communications failure, the UAV must be able to successfully divert to a recovery field on its own while maintaining separation from other aircraft. Currently, validated technology does not exist for such a function. As a result, in the US national airspace system, the Federal Aviation Administration (FAA) has required a lengthy approval process to fly a UAV in controlled airspace, and the UAV must remain under visual control of an operator.

68.2.2 Warning and Alerting Systems

In addition to control automation, there has been a proliferation of warning and alerting systems onboard modern commercial aircraft. Early aircraft had limited, individual alerting systems. As the number of these increased, corresponding to the increase in complexity of the aircraft, the location of many of the visual alerts were consolidated into an annunciator panel, and a master caution warning was added in a highly visible location to indicate that one (or more) of the alerts had activated.

On aircraft that have multifunction displays (MFDs) instead of individual gages (also called *glass cockpits*), the master caution and annunciator panels are often in a less central location. Since the most important alerts can be displayed directly on the MFDs, a master caution and annunciator panel are typically used for less important or infrequent alerts.

Systems Monitoring

Aircraft are complex vehicles, with numerous systems that require monitoring. Engines, the auxiliary power unit (APU), air conditioning, pressurization, electrical systems, hydraulic systems, pneumatic systems, fuel systems, and mechanical systems (such as landing gear) all need to be monitored, and can have failures that are independent from the other systems. On older-generation aircraft, many of these systems (e.g., fuel, electrical, pressurization, and hydraulic) were monitored and controlled by a dedicated flight engineer; a typical flight engineer panel is shown in Fig. 68.5.

On these aircraft, each system was segmented on the panel, and often was laid out in a pattern mimicking the physical layout of the components. For example, the fuel controls (the lower left portion of Fig. 68.5) mirrored the physical location and geometry of the different fuel tanks, cross-flow valves, and boost pumps. This was accomplished to help the flight engineer control the system with fewer errors and to speed diagnosis of problems.

When new aircraft were being built in the 1970s, it was desired to automate most of the control of these systems and to eliminate the flight engineer position. The reasons put forward for this change were to eliminate human error and to reduce crew cost. This change meant that the pilots would be required to handle any malfunctions in these systems, and that systems monitoring equipment would have to be altered for use by the pilots, who would not be able to dedicate time to continuous monitoring or extensive diagnosing of failures.

The new systems monitoring automation is commonly placed on an overhead panel, outside of the normal view of the pilots. Alerts on the front panel (within normal view of the pilots) provide an indication that the pilots should check the overhead panel.

Hazard Monitoring

Pilots must be aware of several different hazards, apart from systems malfunctions. Pilots must monitor for dangerous weather (such as wind shear and thunderstorms), high terrain, and other aircraft. Systems devoted to avoiding collisions will be discussed separately in the next section.

In 1968, a Lockheed Super Electra penetrated a thunderstorm [68.14]. In the resulting turbulence, the aircrew lost control of the aircraft, and overstressed the aircraft (beyond its design limits) in an attempt to recover. The aircraft broke up in flight, killing all 82 persons on board. In 1977, a Southern Airways DC-9 flew into an intense thunderstorm, losing both engines due to heavy rain and hail [68.15]. The engines could not be restarted, and the aircrew attempted to make an unpowered landing on a rural highway. Sixty-two of the 87 people onboard were killed in the ensuing crash.

Modern commercial aircraft all are required to have onboard weather radar to avoid these situations. The system uses common weather radar technology to display areas of precipitation to flight crews.

For aircraft on which weather radar is functioning and available, such incidents do not appear in accident report databases. However, private aircraft are not required to have weather radar on board, and such incidents are still unfortunately common. Weather radar can accurately paint areas of heavy precipitation, enabling pilots to avoid them (and the associated turbulence and lightning). While encounters with such severe weather still occur, they are usually the result of getting too close rather than flying directly into the most severe part of the weather.

A more common risk associated with thunderstorms (for commercial aircraft) is windshear. A windshear is a sudden change in the speed or direction of the wind; downdrafts are similar but involve a shaft of cold air

sinking rapidly toward the ground. Both types of windshear are extremely dangerous in that they can quickly change the lift profile of the aircraft, and have been the cause of numerous fatal accidents.

One of these accidents occurred in 1975. An Eastern Airlines Boeing 727 crashed on landing at Kennedy Airport in New York, killing 112 of the 124 persons onboard [68.16]. The aircraft encountered windshear on final approach, and impacted the ground 2400 ft short of the runway. This incident spurred the US Federal Aviation Administration (FAA) to have a low-level windshear alerting system (LLWAS) developed, and prompted airlines to install onboard windshear alerting systems.

The original LLWAS worked by detecting vector differences in wind through pole-mounted anemometers placed at midfield of the airport and at five locations around the airport. The system alerted if a 15 kt vector difference in the winds was detected, but was prone to false alarms [68.17]. Current LLWAS systems utilize

12–32 sensors, placed at points based on the geometry of the airport and typical convective weather activity, and use more sophisticated algorithms for detecting windshear and microburst activity.

Simple flight deck windshear alerting systems work by monitoring actual and predicted winds entered into the flight management computer. This capability is often augmented by monitoring the groundspeed of the aircraft. Systems have also been developed to use forward-looking infrared radar, Doppler radar or other systems to predict windshear.

Another hazard that aircraft need to avoid is terrain. As a result of a spate of accidents labeled *controlled flight into terrain* (CFIT), instrument manufacturers created a ground-proximity warning system (GPWS). The intent of this system is to detect when an aircraft is approaching the terrain in an unsafe manner (i. e., when not intending to land).

GPWS, and the later enhanced GPWS (EPGWS), utilizes as its primary inputs a radar altimeter (which measures height above ground level – AGL), the barometric altimeter, landing gear position, vertical speed, and airspeed. The EGPWS also utilizes a terrain database and the current aircraft position.

The hazardous condition that the GPWS was attempting to detect was unsafe closure to terrain. Several states of the aircraft were used to determine whether this condition existed, including the altitude of the aircraft, the descent rate of the aircraft, and the status of the landing gear and flaps (to detect when the aircraft was intending to land). Values of these states were combined to produce envelopes of safe operation with respect to terrain; operation outside of these envelopes would constitute a hazardous situation. An example envelope (from a GPWS installed on a US Air Force C-141B) is shown in Fig. 68.6.

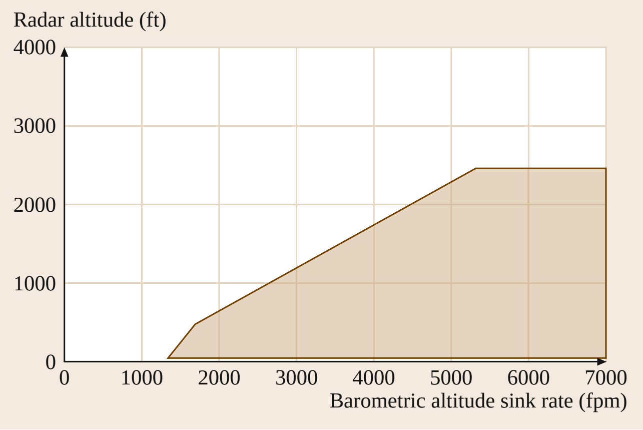

Fig. 68.6 Ground-proximity warning system envelope (mode 1)

The output of the GPWS is either nothing (if a hazardous condition is not detected) or an alert (if a hazardous condition is detected). In the earlier models of the GPWS, an alert consisted of a red light on the GPWS panel and a *whooping* tone followed by a computerized voice that annunciates *pull up* several times. This very distinctive alarm was intended to provide pilots with clear guidance regarding the presence of a hazard and the desired response.

Unfortunately, a number of incidents in which pilots silenced the alarm without complying with the mandated response have occurred, resulting in aircraft crashing into terrain. These incidents were particularly troublesome since the aircraft was perfectly capable, and all the pilots needed to do to avoid crashing was to comply with the alert's desired response.

One supposed reason for this was that the system produced spurious or false alerts [68.18, 19]. These alerts caused trust in the automation to be eroded, resulting in pilots' failing to comply with the alert response. For example, if the system failed to detect that the landing gear was down, the GPWS would sound when the aircraft approached the ground for landing, even if the descent was controlled. In these situations, the pilots would realize that the landing gear was down and ignore the alert.

However, even if the landing gear was down, the GPWS may sound if the aircraft is descending in an unsafe manner (such as would be the case if the aircraft were out of position such that terrain posed a threat to the aircraft). In such a case, merely checking the state of the landing gear would be insufficient. If the pilots assumed that the GPWS was malfunctioning due to it misreading the state of the landing gear, an accident may result.

To assist the pilot with sorting out why the alert was occurring, additional voice alerts were provided as part of the EGPWS, which would help indicate which condition was detected by the system. In addition to *pull up*, the system would also state *glideslope* (if the aircraft were deviating from the desired descent glideslope for landing), *terrain* (if terrain closure were detected), and combinations of these alerts would become increasingly salient if the condition persisted. The low number of such incidents over the last decade suggests that this system has considerably reduced instances of failure to adhere to the ground-proximity warning system.

Collision Avoidance

Avoiding collisions with other aircraft is a shared responsibility between flight crew and air-traffic controllers. When operating visually (under visual flight rules – VFR), controllers are not required to provide any assistance and pilots must *see-and-avoid* other aircraft. When operating primarily on instruments (under instrument flight rules – IFR), controllers continuously monitor the separation of aircraft using processed radar returns, manually monitoring and projecting the positions of aircraft, intervening when potential conflicts are identified.

In addition to see-and-avoid, aircraft collision avoidance systems (ACAS) have been developed. These systems utilize information transmitted from aircraft equipped with an appropriate transponder system to determine relative bearing and closure rate. Should the closure rate and relative trajectories exceed some thresholds, an alert sounds, warning the pilot of a potential collision.

A particular implementation of ACAS is the traffic collision avoidance system (TCAS), whose current implementation is version II. Version I of TCAS (TCAS I), is mandated for aircraft with more than 10 but fewer than 31 seats; TCAS II is used for aircraft with more than 30 seats. TCAS II, which requires that a particular type of transponder (mode S) is in use on the aircraft, coordinates resolution maneuvers if both aircraft are equipped.

TCAS systems detect the transponder signals of nearby aircraft (out to 14 nmi), determining their horizontal range, bearing, and vertical separation from a series of interrogations of the transponders of nearby aircraft. Closure information is calculated from a series of interrogation responses, which is then translated into the time to closest point of approach (CPA).

TCAS has two types of alerts: traffic advisories (TAs) and resolution advisories (RAs). TAs are used to assist the pilot in identifying aircraft that are proximate and may pose a collision danger. No response is required to a TA. RAs warn the pilot of a near-imminent collision danger; specific instructions are included with the alert to avoid the collision. This instruction is a vertical maneuver that has been calculated to avoid the collision. In TCAS II, if both aircraft are equipped, these maneuvers are coordinated.

TCAS must contend with both multipath problems and a condition called *garble*. Multipath refers to one message being received multiple times – once directly from the aircraft, other times after the message is reflected off the ground or other obstacles. TCAS must know which of these is the original signal. Garble refers to the overlap of signals. Since the messages are 21 µs long, several messages can overlap; TCAS must still be able to decipher messages under these conditions.

TCAS must also balance the probability of missing a detection (MD) against likelihood of a false alarm (FA). As mentioned previously, FA has a deleterious effect on automation trust; however, one also would like all hazardous situations to be detected. In TCAS, the *sensitivity level* (SL) of the system can be modified to change the tradeoff point between MD and FA.

A sensitivity level of 1, in which the aircraft does not issue any alerts, can be selected by the pilot, or occurs whenever the system goes into standby mode (for example, when the mode S transponder fails). The pilot can also select a SL of 2, where the system only transmits TAs. Sensitivity levels 4–7 are selected by the system automatically, depending on the altitude of the aircraft. As the altitude of the aircraft increases, the sensitivity level goes up. With higher sensitivity levels, the system alerts sooner.

TCAS uses both a time to CPA (τ) and the absolute horizontal and vertical separations between aircraft. The primary determinant of the alerts is τ, but when closure rates are very low, aircraft can come very close to one another without violating τ (imagine aircraft on almost parallel courses, slowly converging). If τ (both the

Table 68.2 Alert threshold for TCAS II version 7 (after [68.20])

Actual altitude (ft)	Sensitivity level	τ (s)		DMOD (nmi)		Threshold altitude (ft)	
		TA	RA	TA	RA	TA	RA
Below 1000	2	20	–	0.3	–	850	–
100–2350	3	25	15	0.33	0.2	850	300
2350–5000	4	30	20	0.48	0.35	850	300
5000–10 000	5	40	25	0.75	0.55	850	350
10 000–20 000	6	45	30	1	0.8	850	400
20 000–42 000	7	48	35	1.3	1.1	850	600
above 42 000	7	48	35	1.3	1.1	1200	700

vertical and horizontal τ) of a proximate aircraft is less than the thresholds, the alert sounds. Otherwise, if the closure rate is low, the alert will sound if both the horizontal and vertical separation is less than the DMOD (which is short for *distance modification*) and altitude thresholds, respectively. These thresholds for SL 3–7 are shown in Table 68.2.

68.2.3 Information Automation

Information automation is distinguished from other types of automation as it is intended to provide information to support reasoning by the operator (as opposed to supporting rule-based or skill behavior). Information automation includes the most recent forms of automation.

Automated Checklists

Electronic versions of checklists have been introduced quite recently, including in the Boeing 777 [68.22, 23]. These checklists reproduce, on a display, the steps of the checklist. As items are completed, they are presented as completed after the item is actually completed (as checked by automation, if possible).

Cockpit Display of Traffic Information (CDTI)

A display of nearby aircraft is part of the ACAS system. Such systems show aircraft within a certain range that may pose a collision or separation risk. Along with relative bearing, their relative altitude, identification, and sometimes speed are shown.

A number of researchers have examined how such displays may be utilized to improve the situation awareness and conflict avoidance capabilities of pilots [68.24–27]. Some have gone as far as suggesting that such displays can be utilized (in part) to enable flight-deck-based separation, as opposed to separation assured by centralized ground authorities such as air-traffic controllers [68.28, 29].

In such displays, all aircraft within the range selected for the display are shown, including all pertinent information such as altitude and speed. An example is shown in Fig. 68.7.

There are some issues with CDTI, however. These issues include displaying three dimensions on a two-dimensional display, perspective issues, and clutter.

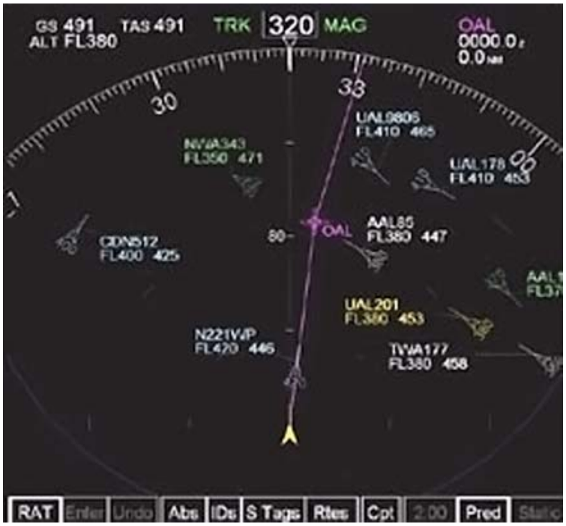

Fig. 68.7 NASA flight deck display of traffic information (after [68.21])

Because aircraft fly in three dimensions, air traffic is nominally a three-dimensional task. However, aircraft in cruise are stratified; they fly at altitudes in the whole thousands (35 000 ft, 36 000 ft, etc.). Because of this, except when climbing and descending between these altitudes, an aircraft's altitude is essentially a category rather than a state. Moreover, it is treated as such by flight crews and controllers, who refer to aircraft above 18 000 ft (below which climbing and descending is more frequent) as being at a particular *flight level* (FL), which are measured in hundreds of feet. So an aircraft at 35 000 ft is referred to as being at FL350.

In addition, the scales of horizontal and vertical separation are different by almost an order of magnitude. Vertical separation is given in thousands of feet; horizontal separation is given in nautical miles (just over 6000 ft). It is not even possible to display these scales simultaneously on a display and have the information be adequately discernable. In order to create a three-dimensional display of traffic, one scale or the other must be distorted. For these reasons, air-traffic control is not typically addressed as a three-dimensional problem.

Designers of CDTI must also consider issues of perspective in displaying traffic. Each perspective distorts or obscures some aspect of the situation. A top-down view (typically used in navigation displays) completely eliminates relative vertical position, which is then often replaced by a text display of altitude. In general, there is ambiguity in position information along the line of sight of the display [68.30]. A display oriented to the pilot's perspective (referred to as *immersed*) eliminates information to the side, from behind, and from above the aircraft. This results in a *keyhole* view of the world [68.31].

Researchers have shown that having the viewpoint outside the flight deck provides the best performance for mapping between the world and display [68.32]. In doing so, the principles of pictorial realism (the display should be pictorially analogous to the real world) and integration (related information should be integrated on the same display) can be followed [68.33].

Heads-Up Displays

Heads-up displays (HUDs) and helmet-mounted displays (HMDs) were first introduced in military aircraft to reduce the amount of time a pilot spent looking inside the flight deck. By positioning frequently accessed information on a display that one could see through to the world behind, pilots need only change the depth of focus to extract information from the world or the instrument, rather than moving the head, eyes or both.

Such displays are now finding their way into commercial aircraft (and even automobiles). The advantages of such a display are clear. For example, one can easily integrate real-world information with displayed information. Also, the HUD enhances the operator's ability to alternate between information at different depths [68.34].

However, several disadvantages should also be considered by designers. First, by superimposing information on the *world* background, the danger of clutter increases. However, researchers have shown that pilots are able to ignore the background information so that no additional workload is imposed on the pilot [68.35]. Also, should unexpected events occur, it appears that the HUD may reduce the capacity of the operator to detect these events, although it is not entirely clear why this is the case [68.36].

Data Communications

Currently, most communication between air-traffic control and flight deck utilizes voice channels over radiofrequencies. On commercial aircraft, communication between a company's dispatch (called the airline operation center – AOC) and an aircraft mostly happens over data channels utilizing satellite communications. There have been proposals to replace some or all of the air-traffic voice radiocommunications with data communications (*datacomm*). Datacomm is similar to email in that the messages are transmitted digitally and displayed as text, rather than transmitted across voice channels.

One of the main reasons for this change is frequency congestion. All aircraft under the control of a particular air-traffic controller monitor and communicate on the same frequency. In dense airspace, such as close to the airport, the number of aircraft and the amount of maneuvering results in a high volume and rate of communications. Since by regulation each air-traffic communication must be *read back* by the pilot of the aircraft for which the instruction was intended, this volume can exceed the channel capacity. In such cases controllers may even continue to the next instruction without waiting for (or getting) the read back of the previous instruction.

In addition, many errors are associated with communications read back. Pilots may read back the clearance correctly but fail to recall it correctly, or they may read back an incorrect clearance that is subsequently not noticed by the controller. Cases in which the wrong aircraft has read back the clearance have also occurred. It is expected that datacomm would alleviate many of these communications errors.

In addition to equipment and certification cost, one of the main issues arguing against datacomm, however, is party-line information loss. Since all aircraft under the control of a particular air-traffic controller are monitoring the same frequency, they would hear communications with other proximate aircraft, including aircraft preceding them on the same route. This allows pilots to glean information about the relative positions of other aircraft, their intentions, and the intentions of the air-traffic controller. For example, pilots hear other aircraft preceding them asking for altitude changes due to turbulence; this allows them to request the same change before the turbulence is encountered. With datacomm, such information would be unavailable to pilots.

68.3 Guidelines for Automation Development

Flight decks are highly automated and have many different types of automation. In this section, the important principles for the development of automation are discussed. First, principles related to each of the types of automation (control, warning, and information) are discussed. This is followed by several overarching concerns for the development of automation – human factors issues, system integration issues, safety, and certification.

The guidelines listed here are not necessarily followed in the development of current automation. One reason for this is that it is often impossible to follow all guidelines regarding automation and still meet all other constraints (such as space, cost, and certification). As such, these guidelines should be treated as goals for automation development rather than hard-and-fast rules.

68.3.1 Control Automation

Control automation must be demonstrably controllable and observable. Controllable means that, for any bounded input, the output will be bounded. If an aircraft is not controllable, the autopilot may (for example) not have sufficient control authority to dampen out errors, resulting in continuously escalating error between desired and commanded state. Observability means that the values of the states are known to the controller. If these states are not known, the controller will not know to apply control, again resulting in a potential loss of control of the aircraft. Controllability and stability are demonstrated mathematically using control theory approaches (which can be found in any feedback control textbook).

Control automation should make apparent the axes under control and the expected behavior of the automation. Due to the desire to be able to control axes separately under certain circumstances, there are a number of modes in which the autopilot can be operated. Typically these modes are not clearly identified to the pilot, or, if they are, the expected operation of the aircraft while in these modes is not well understood. A number of aircraft accidents have occurred due to this *mode confusion*. A number of researchers have investigated this problem and proposed solutions [68.10, 37–40], but to date no particular method for mitigating the problem has been widely adopted. Designers of future control automation, however, must strongly consider the likelihood of mode confusion, and use good human factors design methodology to ensure the transparency of the automation.

Control automation should fail gracefully. It is possible for the aircraft to be exposed to conditions that exceed the expectations of the designers. Such conditions are often cases where the pilots could use the assistance of automation, but where automation typically turns itself off. Autopilots are designed to be used under specific sets of flight conditions; if exceeded, autopilots will simply disconnect, leaving the pilot to handle the unusual circumstance by themselves. To the extent possible, control automation should be designed to assist pilots even in unusual circumstances rather than just shutting off.

68.3.2 Warning and Alerting Systems

Warning and alerting systems are designed to identify hazards. If this identification (and the corrective action) were deterministic, there would be no need to alert (the system should operate automatically to perform the corrective action). Typically, the system acts as a signal detector, alerting based on some threshold of evidence regarding the hazardous condition.

Signal detection theory provides a convenient and effective way of analyzing alerting systems. If the detector is correct in identifying the signal, then the detection is considered *correct*. Otherwise, the detection is considered a *false alarm*. If, on the other hand, the system does not alert and is wrong (i. e., it should have alerted), that is considered a missed detection. A correct rejection is the final case, where the system correctly does not alert.

Given an equal cost of a missed detection and false alarm, thresholds should be set to minimize missed detections and false alarms. Such a tradeoff can be viewed on a system operating characteristic (SOC) chart, such as that shown in Fig. 68.8. The *chance* or *guess* line is

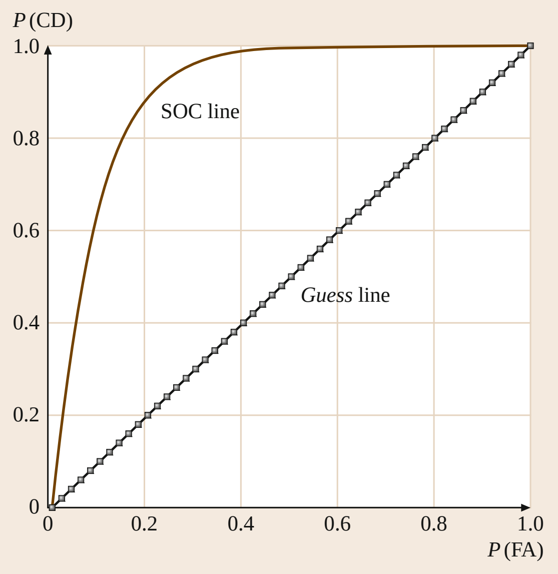

Fig. 68.8 System operating characteristic chart

the 45° diagonal on the chart. The curve is constructed by manipulating the alert threshold and determining the resulting probability of false alarm and correct detection. Different system designs will result in different curves. In the SOC chart, the *perfect* system operates in the upper left corner of the chart, where the probability of false alarms is zero and the probability of correct detections is 1.

Since perfect performance is not possible, the system should be operated using the alert threshold that is as close as possible to the upper left corner of the SOC chart. Moreover, since correct detections and false alarms are typically not valued equally, the best point on the SOC curve is determined by the relative value of the correct detections and false alarms. In particular, for the given curve, one should attempt to maximize the value of

$$U = P(\mathrm{CD})V(\mathrm{CD}) - P(\mathrm{FA})V(\mathrm{FA})\,. \tag{68.3}$$

For collision detection systems, there is another consideration. If a false alarm occurs, it is possible that the resulting actions of the pilot will induce a collision that would not occur if no action had been taken. Therefore, such systems must also consider *induced collisions* as a metric. Other types of alerting systems should also consider the full effect of false alarms on resulting system performance.

Alert thresholds should include consideration for pilot response time, which will vary considerably based on the frequency of the alert. Often alert thresholds are set based on assumptions about the resulting response. For example, ACAS systems often expect a pilot to initiate the resolution maneuver within just a few seconds. However, many alerts are uncommon, sometimes only heard a few times in the career of a pilot. Expectation seems to affect pilot response to alerts, and pilots have been known to take 30 s or longer to respond to alerts [68.41–43]. If the alert thresholds are set assuming a 5 s response time, but that threshold is not met, the alert may come too late to be effective.

Expected responses (often included in the alert threshold) should also reflect heuristics, as pilots will often apply common shortcuts (or techniques) when executing a response, even if that response is not consistent with that expected by the alert. For example, prototype alerting systems for collision avoidance on approach assume that the pilots will turn away from the approach path of the other aircraft, and the alert thresholds are set assuming this response [68.44, 45]. However, military pilots are trained to always keep proximate aircraft in sight so that separation can be assured visually. A turn away from an aircraft violates this heuristic and may not be followed.

Wherever possible, preparatory warnings should be given. It has been shown that adherence to desired actions subsequent to an alert improves if the alert is preceded by a preparatory warning [68.46, 47]. For example, the traffic collision avoidance system (TCAS), a type of ACAS, utilizes a two-level warning system. A traffic advisory (TA) is first given to warn of a proximate aircraft that may pose a threat. No action is required due to the TA (although some action presumably should be taken, even if it is to confirm the threat). If the condition persists, a resolution advisory is given to indicate the high potential for collision. Resolution advisories provide specific guidance to the pilots to avoid the potential collision; pilots must comply with the resolution advisory instructions.

68.3.3 Information Automation

During periods of high workload, pilots will have little time to scan a display looking for information. For that reason, information automation must avoid clutter – the presentation of useless information alongside useful information. This coincidence of information forces the pilot to search a display, utilizing time and cognitive resources in short supply during times of high workload.

However, the designer often cannot identify useful information a priori. In this case, there are a number of methods to declutter a display, although no definitive methods have been identified. Decluttering eliminates low-priority information, or information that is unlikely to be needed, from the display. One method is to utilize multifunction displays (MFDs) instead of single-sensor, single-instrument (SSSI) displays. MFDs allow for depth, where information can be put on separate *pages* of the display that can be brought up when needed or when called for by the operator. The information is then present in the system but not visible until needed. For example, automation onboard flight decks will display information related to a malfunction when that particular malfunction is detected.

Two tradeoffs when using MFDs are the possibility that information is presented when not needed (or not presented when needed) by the automation, and the need to navigate through the display. It can be difficult for the designer to envision all the circumstances involved that lead to a pilot needing information displayed, or needing the display to remain the same. Moreover, for such automation to be used, it should be highly accurate at predicting the information needs of the pilot.

When depth is introduced into displays, the pilot must navigate through that depth to arrive at a particular set of information, just as people navigate through the depth of webpages. On flight decks, information displays are typically very small (a few inches by a few inches), so for the same amount of information more depth is needed than on a conventional laptop-sized display. Moreover, fewer controls are provided to navigate through the displays, making the task even more difficult.

Another method to declutter displays is to deemphasize some information by reducing its contrast, brightness or both. Important information will then *pop out* of the display, and unimportant information will be easier to ignore.

Recent work on visualization may provide some assistance [68.48, 49]. Visualization approaches attempt to provide information in a format that eases interpretation, allowing more information to be extracted from a display for a given amount of information presented. However, such approaches have yet to be validated for use in such safety-critical systems as a flight deck.

68.3.4 Human Factors Issues

Our ability to create automation capable of replacing a function previously done by a human is becoming largely dependent upon human factors issues rather than technical ones. With computers becoming smaller and faster, it is technically possible to produce automation capable of remarkable feats. However, if that system must interact with humans, it must be compatible. This problem of compatibility is often a major obstacle to the introduction of automation into complex sociotechnical systems.

Such automation must consider a number of aspects of human interaction with technology. The role of human in a highly automated system is often relegated to that of a supervisor. This role has particular requirements and challenges that must be considered by the designer of automation. One of these challenges relates to the *out-of-the-loop* problem [68.50], which is being addressed in terms of understanding the operator's awareness of the situation. In addition, automation must incorporate human limitations with regards to perception, workload, and physical ergonomics.

Supervisory Control

As flight deck automation increases in quantity and sophistication, some have expressed concern that pilots are becoming supervisory controllers of automation rather than users of automation. On some aircraft, it is possible to connect the autopilot once aligned on the departing runway, and allow the aircraft to fly to its destination, land, and taxi off the runway without interacting with the aircraft control surfaces (except drag/lift devices such as flaps and spoilers) except through the autopilot.

One concern related to this phenomenon is the loss of manual control skills, as discussed by *Billings* [68.51] and others [68.52, 53]. Should the automation fail, the pilots would have to fly the aircraft manually. Since such failure is likely to result from a more serious system failure, such control may have to be assumed under less than ideal circumstances. For example, the aircraft may have only partially operating control surfaces, as was the case with a DC-10 mishap in Sioux City, Iowa in 1989 [68.54]. In that accident, an uncontained engine failure left the aircraft without hydraulic power to operate any of the control surfaces. The pilots controlled the aircraft using engine power only, a procedure that had to be created by the pilots on the spot. Without excellent manual flying skills, it is unlikely that the result would have been as successful (175 of the 285 passengers and all but one of the crew survived the crash landing). Designers of automation should ensure that sufficient opportunity exists for the operators to exercise those aspects of control for which an intervention need may arise in the case of automation failure.

The overarching considerations that are part of supervisory control [68.55] should be considered when designing automation for flight decks. These considerations include the ability of pilots to monitor information, an understanding of the impact of communications/control delay, and loss of situation awareness.

As supervisors of automation, pilots are responsible for monitoring the automation to ensure it is operating properly and to intervene should the automation fail. Humans are notoriously bad at monitoring highly reliable systems [68.56]. Under such conditions, humans will tend to become complacent and fail to monitor adequately. One response to this has been to suggest caution against overautomation [68.51], while others have suggested that more automation (or at least feedback) is the answer [68.57]. Likely what is required is smarter automation, including designs that make a system fail only in ways that can be handled by a human supervisor.

Even relatively small delays in communication or control can have significant consequences for supervisory control. This is analogous to manual control, where delays between identification of control requirement and application of that control can lead to instability. For faster control loops, less delay is required; for slower control loops, longer delays can be tolerated. For example, under conditions of several seconds of delay, intervention by a supervisor to accept manual control would likely be impossible, whereas such delays would not impact the supervisor's ability to provide navigation commands to a vehicle.

In addition, humans have better situation awareness when actively involved in the operation rather than when acting as a supervisor of automation [68.58, 59]. Situation awareness is the set of information used by the operator in order to make decisions and choose courses of action, and will be discussed in more detail in the next section. Good situation awareness, considered a key to good performance in complex systems, is adversely affected by the operator's cognitive distance from the task. This may be a result of research findings suggesting that concrete, direct experiences involve deeper cognitive processing, and are therefore better recalled than those that are merely described or otherwise undergo more shallow processing [68.60].

Situation Awareness, Clutter, and Boundary Objects

Since situation awareness is correlated with good performance, automation designers should attempt to enhance situation awareness. However, this cannot be addressed by simply making sufficient information available and salient to the operator, since situation awareness involves the operator making use of that information. Making information available is not sufficient for ensuring that the information gets used; operators may simply fail to use available information for guiding action for reasons that are as yet unclear. For example, one aviation incident self-report from the National Aeronautic and Space Administration (NASA)'s aviation safety reporting system database describes landing at the Los Angeles International Airport without first obtaining landing clearance as required by FAA regulation. The crew, who would normally switch their radiofrequency to that of the tower controller (who would then grant landing clearance), was told to remain on a previous frequency by air-traffic control (most likely due to some separation concern). As a result, the crew never switched frequency and never got landing clearance. They realized their mistake after turning off the runway, at which point they were about to switch to the frequency of the ground controller. Noticing the error, the crew called the tower and reported their mistake. The crew in this incident had sufficient information to know they did not have clearance; they simply did not make use of that information. While factors such as interruptions (and other disturbances to a routine), workload, idiosyncratic cognitive capabilities, and experience would seem to influence the prevalence of this type of behavior, as yet no definitive research has been accomplished to understand it.

Automation designers should be aware that the absence or lack of salience of information, while not technically a part of situation awareness, will have the same effect as a loss of situation awareness. That is, not having the information in the first place will have an identical effect on performance as not making use of available information (although the causes of the error may be different). One method to ensure this is to conduct a thorough task analysis [68.61], such as goal-directed task analysis [68.62]. Such methods provide insight into what information may be required by an operator in the conduct of their task.

In addition to ensuring the availability of information, designers should ensure that information is accessible to the operator. Too much irrelevant information can make accessing particular (important) pieces of information more difficult than necessary [68.35, 63]. For this purpose, a number of decluttering schemes are available [68.64–66].

Intelligent design of displays, so that multiple operators across a collaborative task can easily contextualize information while making use of the same body of information, is also recommended. Such displays, known as boundary objects, have been found in examples of good collaborative work [68.67, 68]. Unfortunately, design criteria for these types of displays are still lacking.

Situation Assessment

Automation designers should consider the situation assessment capabilities of the pilots. Situation assessment is a term that refers to the process of populating situation awareness. Situation assessment involves most aspects of cognition – perception, attention, comprehension, memory – and is therefore very complex. These limitations are discussed in subsequent sections. However, several important overarching findings bear on this capability.

Operators monitoring dynamic displays do so at a near-optimal rate under most circumstances. According to the Nyquist–Shannon sampling theorem [68.69], one can fully reproduce a signal if that signal is sampled at more than twice the signal's frequency, if the signal is bandlimited. Operators have been found to sample at precisely this rate, with some deviation at higher and lower frequency [68.70]. For highly dynamic information, operators will oversample, while they tend to undersample low-frequency information. Numerous reasons have been proposed for this tendency, without a definitive answer. However, designers can feel somewhat comfortable that human operators will sample dynamic displays appropriately.

However, as mentioned above, operators become easily complacent with highly reliable or very low-frequency information. In such cases, designers should, where practical, ensure that operators are engaged in the task. One method, utilized in airport security x-ray machines as the threat image protection system, is to occasionally probe the operator with false signals. Such signals can be used to engage the operator but also to test to see if the operator is becoming complacent. Another method is to increase the salience of potentially offending signals, such as providing a warning light to attract the attention of the operator to the instrument containing the relevant information.

In addition, operators have significant cognitive limitations (but also have several methods of coping with these limitations). A human's channel capacity is limited to somewhere between four and nine individual items [68.71, 72]. Above this, operators must be able to *chunk* the information (such as recalling a phone number as one seven-digit number rather than as seven separate digits in a sequence). Expertise improves the ability of operators to chunk information, but designers are cautioned not to design automation that taxes a human's channel capacity.

Perception

In terms of visual perception, human operators sparsely sample scenes, then integrate their knowledge of the world with these sparse samples to obtain a representation. One factor known to affect sampling is the Gestalt of the scene [68.73]. Factors such as the proximity of items, their *common fate*, and their similarity all affect the ability of the operator to associate information. An example of this ability regards the monitoring of a number of check-reading gages. Gages oriented so that their limits are aligned (Fig. 68.9) are much easier to monitor than those that are not. Designers are therefore encouraged to consider the Gestalt of instruments to assist operators, including grouping information used for the same purpose close to one another [68.74].

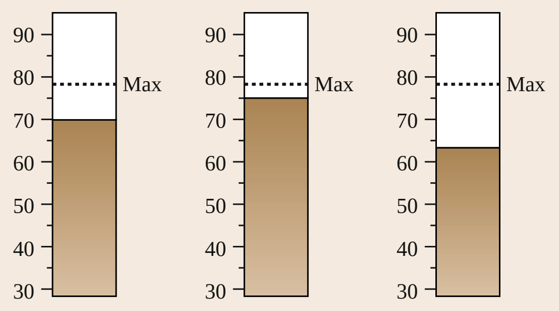

Fig. 68.9 Aligned gages for Gestalt effect

The basic layout of flight deck instrumentation was established many decades ago, based on research into the scan pattern of pilots [68.75]. This placed the most-used instruments into a T-shaped pattern (now called the *basic T*), with less-used instruments being placed outside of this T, but close to related instruments. The basic T has been replicated on multifunction displays utilized in modern aircraft in place of single-sensor, single-instrument gages. It seems certain that this arrangement will continue, and should be adhered to by automation designers.

Workload has been known to affect perception and attention, as has been widely reported in studies on driving [68.76, 77]. Increased workload impairs visual detection, as well as the size and shape of the visual field [68.78]. Increased workload also dissipates attention, which in turn influences perception. Designers should be aware that, under conditions of high workload, pilots may have difficulty in perceiving information that would otherwise be considered sufficiently salient.

Much of the information imparted to the user by flight deck automation uses the visual channel. In order to avoid further saturating the visual channel, designers are reminded that other perceptual channels are available. Several automation systems use the aural channel, particularly alerting systems. The GPWS, the stall warning system, the landing gear warning system, and a number of others produce both visual and aural warnings; each aural warning is distinct to aid in identification. Very little work has been done in trying to utilize the haptic medium in aviation, but some success has been found in aiding operators in locational attention directing [68.79], which could be useful for pilots.

Workload

Often the primary concern related to workload is to ensure that the work required of an operator does not exceed the operator's capability. Pilots experience swings in workload from very high (takeoff and landing) to very low (cruise). The periods of high workload are such that almost no cognitive work, required for reasoning and other higher-level functions, can be accomplished. Instead, pilots are relegated to skill-based control [68.80], and do not have time for things such as mental calculation or troubleshooting. Imposing requirements for such activities during high workload periods should be avoided.

Performance in complex tasks has been showed to be inverse-U shaped with respect to workload [68.81, 82]. At low levels of workload, human performance is low due to complacency. At high levels of workload, performance is also low, but due to task demands taxing or exceeding human capabilities. Performance is highest at moderate levels of workload. Automation designers should therefore try to balance workload (not too high and not too low), rather than strictly trying to reduce it.

Physical Ergonomics

Automation designers should consider good physical ergonomics as well as cognitive ergonomics. For automation, several factors are considerations, including repetitive strain avoidance, placing frequently used controls within reach, ensuring proper visibility and audibility, and reducing the *heads-down* time of the operator.

Automation should avoid requiring significant fine input from the operator. The flight management system (FMS) includes a control display unit (CDU), which is the primary manual interface for the pilot with the unit. Pilots may need to input information into the FMS using the CDU, which consists of a small keyboard and display. The keys on the CDU are small, mostly identically shaped, and laid out in an idiosyncratic (to the particular CDU) manner. This layout is far from ideal from a human factors standpoint, and results in a slow rate of typing. Should significant typing be required, repetitive stress injuries (such as carpal tunnel syndrome) would be a significant risk. However, designers of the CDU must contend with a very small device footprint, it must have very high reliability, and it must be robust to flight conditions such as turbulence. Fortunately, most of the information in the FMS is loaded only once (or by electronic download), so typing is infrequent and usually limited to a few key presses.

There are numerous principles for controls to avoid the chance of repetitive strain or overuse disorders [68.82]. These types of injuries are associated with high-frequency activity, and therefore can be avoided by eliminating prolonged periods of repetitive motions. High repetitiveness has been defined as a cycle time of less than 30 s, or more than 50% of the total task time [68.83]. Larger loads can induce the same conditions with less repetition. Maintaining body positions (other than the neutral body position) or gripping objects can also induce repetitive strain injuries. According to *Kroemer* et al. [68.83], there are seven *sins* associated with overuse disorders:

1. Highly repetitive motions
2. Prolonged or repeated application of more than one-third of an operator's static muscle strength
3. Stressful body postures, such as elevated wrists when typing or working while bent or twisted at the waist
4. Prolonged nonneutral body postures, such as standing
5. Prolonged contact with a surface, such as leaning against a surface or holding a tool
6. Prolonged exposure to vibration
7. Exposure to low temperatures (such as a draft or exhaust from a pneumatic tool).

Certain types of reaching are ergonomically undesirable. The need to extend oneself to reach a control poses risks to the back and shoulders, as does the need to reach above one's shoulder height [68.84]. The need to twist one's body frequently also poses significant risk of injury to operators. For these reasons, it is a common ergonomic principle that frequently used controls be placed within the normal reach of the operator.

To find the normal reach of the operator, one should first identify the range of sizes of the people that constitute the population for which the device will be designed. A common choice is to use a 5th percentile female as the lower limit and the 95th percentile male as the upper limit. However, certain occupations may further limit the population.

If single measurements are required (such as shoulder–hand length), lookup tables, such as those that can be obtained from NASA or commercial sources, can be used. If multiple measurements are required, however, *cases* should be considered rather than trying to combine measurements from the tables. Cases identify a typical small or large person, rather than assuming that a small person has the 5th percentile seated height and 5th percentile shoulder–hand length (for example), which is usually not accurate.

Once the lower and upper measurements have been obtained, the designer can then check to see whether the commonly used controls are within the reach of that range of persons without extending. Such methods have been applied in a great number of different domains.

Proper visibility should be ensured throughout the typical illuminance conditions. Studies that provide guidance on illuminance were conducted decades ago, including studies in which *Blackwell* [68.85] found that the threshold contrast at which objects became recognizable increased with decreasing object size, decreasing orderliness of objects, movement of the objects, and if less time was given to detect the object. Increased age also increases the need for contrast [68.86].

In addition, the viewing of displays should be free of glare and veiling reflections. Glare is the condition where bright light sources are in the line of sight of the operator, creating a nuisance. Veiling reflections are the condition where bright light sources are reflected off the display surface, obscuring information on the display. These problems can be minimized by positioning the display where bright light sources pose neither a glare or reflection issue (to the maximum extent possible).

Automation designers should also ensure audibility, particularly of aural feedback or alerts. An alert that is at least 10–15 dB above the ambient noise level is generally considered sufficiently salient, although alerts are often found with significantly less difference when placed in the normal operating environment (a flight deck is a noisy place in flight). Different types of tones can also be used to indicate different levels of criticality [68.87].

When multiple auditory warnings exist, as they do on flight decks, they should utilize distinct tones to avoid confusing one alert with another. Some alerts may even include computerized voices. On a typical flight deck, auditory warnings exist for the GPWS system, TCAS system, overspeed warning, landing gear warning, and altitude alerts.

When the weather permits, pilots must direct a significant amount of attention to outside the flight deck. In addition to visually locating other aircraft that may pose a collision risk, pilots must frequently locate, identify, and orient themselves with respect to a particular airport runway. On the ground, scanning for obstacles and other aircraft is a particularly important task. For this reason, automation should not impose upon pilots too much *heads-down* time (the term is contrasted with *heads-up* displays located on the windshield of the aircraft). Flight management system reprogramming, for example, is a difficult task, requiring many minutes of heads-down time to accomplish relatively simple reprogramming tasks. It is therefore undesirable to have changes close to the ground, where pilots' attention should be outside rather than inside the aircraft.

68.3.5 Software and System Safety

Calls have been made previously for automation that gracefully degrades [68.51, 55], but there has been a general lack of guidelines for such a purpose. One significant complication for the introduction of such methods is that most advanced automation is software rather than hardware based. Software systems lack physical constraints available in hardware. Whereas one can construct physical constraints on machines that prevent them from failing in certain ways (e.g., short-circuit protection devices on electrical outlets in bathrooms), no such assurances can (so far) be provided for software systems. Formal methods for mathematically verifying software [68.88], particularly in concert with model-based software development methods [68.89], are methods that go far toward improving software systems in this regard.

Formal methods, however, are insufficient for ensuring software safety [68.90]. Safety is often more than ensuring that the output of the software remains within some constrained set of appropriate responses. Safety also involves the processes for defining those constraints and the interaction of human and other automated agents with the system. Therefore, system safety must also account for these (and other) factors.

Because of this, safety has been viewed as an emergent feature of a system, ensured by providing sufficient control for agents in the system to prevent it from entering unsafe states [68.91]. Under this concept, a system can be modeled as a set of states, where safety (as a goal) is preventing the system from entering an unsafe state.

68.3.6 System Integration

As flight decks get more complex, and as the interactions between systems (other vehicles, air-traffic controllers, passengers, company) become tighter, system integration issues will grow in importance. Aircraft have been typically designed to optimize some aspect of the vehicle (for example, speed, fuel economy, range or capacity), but now must consider the integration of that vehicle within a larger system. There are tight interactions between customer demand, airline route decisions, air-traffic control infrastructure, and aircraft design.

Such design optimizations involve multiple systems, each of which have very different dynamics. The behavior of the system is not defined by the sum of the behaviors of the components, but typically also has emergent behavior at higher levels of aggregation of the components. Methods for accomplishing such optimizations have not yet been developed, but are being studied as *systems-of-systems* problems.

Nonetheless, automation designers must address systems integration issues. Flight deck automation is expensive to develop and implement, and therefore must last many years (typically the lifetime of different aircraft models). For example, flight management systems have hardware and software that is highly antiquated by modern computer standards, but because it works and is certified (Sect. 68.3.7), it has not substantially changed over the last few decades. Moreover, the flight deck automation needed to take advantage of next-generation air-traffic systems will need to be developed and installed over the next decade.

Flight deck systems often interface with multiple systems of various types. State information on aircraft comes from pito-static, temperature, and other instruments. Position and navigation information come from radio navigation aids, inertial navigation systems, GPS, and the flight management systems. There are also mechanical, electrical, hydraulic, and pressurization systems onboard. Potentially, automation must be integrated with several of these different types of systems.

68.3.7 Certification and Equipage

The various civil flight authorities have strict certification requirements for new automation. These requirements impose rigorous safety requirements on that automation. This results in long lead times and high costs, which in turn imposes a heavy burden on any new automation system being proposed.

In the USA, the Federal Aviation Administration certifies new equipment. Under the Code of Federal Regulations, each installed system must:

1. Be of a kind and design appropriate to its intended function
2. Be labeled as to its identification, function or operating limitations, or any applicable combination of these functions
3. Be installed according to limitations specified for that equipment
4. Function properly when installed [68.92, p. 125].

In addition, for flight and navigation instruments:

1. The equipment, systems, and installations ... must be designed to ensure that they perform their intended functions under any foreseeable operation condition.
2. The airplane systems and associated components, considered separately and in relation to other systems, must be designed so that:
   a) The occurrence of any failure condition which would prevent the continued safe flight and landing of the airplane is extremely improbable.
   b) The occurrence of any other failure conditions which would reduce the capability of the airplane or the ability of the crew to cope with adverse operating conditions is improbable.
3. Warning information must be provided to alert the crew to unsafe system operating conditions, and to enable them to take appropriate corrective action. Systems, controls, and associated monitoring and warning means must be designed to minimize crew errors which could create additional hazards [68.92, p. 126].

The certification process is detailed and slow, designed to prevent systems with deleterious safety effects from being installed in aircraft (particularly commercial aircraft). This process, which is well known to the industry but is not well documented, should be considered by automation designers. The use of off-the-shelf and previously certified hardware and software is recommended to simplify and shorten the certification process.

68.4 Flight Deck Automation in the Next-Generation Air-Traffic System

As of this writing, the next-generation air-traffic system is still taking shape [68.1, 2], but the following appear to be emerging as key features of that system:

- Network-centric operations
- Integration of novel vehicle types
- Operations under conditions of very high density

- Tight coupling between passenger demand, airportal infrastructure, aircraft operations, and air-traffic control.

These capabilities are designed to allow the next-generation system to handle two to three times the capacity of the current system by 2025.

68.4.1 Network-centric Operations

Currently, most information in the air-traffic control system is contained locally within each air-traffic control facility. The exception to this is the enhanced traffic management system (ETMS) data, which is available to all air-traffic control facilities and even users (with a slight delay). However, ETMS data is significantly limited in content and in update rate. Under future concepts, all air-traffic information will be made available (with some restrictions) to all agents in the system, in order to facilitate better collaborative work. This concept is referred to as *network-centric operations*.

The various air-traffic control authorities in different countries are currently building the network infrastructure. This infrastructure will carry real-time flight plan information and radar track information, which (in the USA) is currently carried in the Department of Transportation's *aircraft situation display to industry* (ASDI) data stream with one minute (at best) update rate, but also may include such things as aircraft intent information, scheduling information, aircraft load information, airport and airspace capacity, and airline priority information. The ability to use this information should provide unprecedented opportunities for automation developers.

For example, there has been little success in optimizing sequences of aircraft into congested resources such as airports. The current system allows aircraft to launch when they want and fly at any speed to their destination, where they may then have to be delayed for tens of minutes or more. Moreover, decisions about which aircraft get delayed are made based on a first-come first-served basis.

While this can be considered at least *fair* (in that no company gets an advantage from it), it is certainly not optimal. It would be preferable to sequence aircraft based on best throughput or least delay (for aircraft or passengers). Without any information available in this regard, it has been extremely difficult to improve the air-traffic system in this regard. With a single data source, systems could consider many factors when deciding on which aircraft to delay, and could start that delay early, imposing small changes that have significant effects on the overall system.

The methods to accomplish such optimizations have not yet been developed. Some attempts at optimization have been made, but are limited in scope. It is not yet clear how one can formulate optimization problems of this scope (or solve them in a reasonable period of time). Moreover, whatever solutions are produced must provide guidance on how to construct trajectories of individual aircraft.

68.4.2 Future Air Vehicle Types

Decades ago it was believed by many that, by this date, air travel would be dominated by supersonic transports. Due (in part) to noise and fuel consumption issues that has not occurred, although research continues on super- and hypersonic transports. As experts peer into the future of air transportation, it is unclear what types of vehicles will be present in the air-traffic system in 50 years.

The last few years has seen a significant increase in the use of small regional jets, due to their higher load factor (i. e., higher percentage of seats filled with paying customers). Airbus has also just introduced the A-380, the largest passenger transport jet ever produced, with seating for 550 to over 800 passengers depending on the configuration. Boeing is developing the B-787, a large (210–330 passenger) jet with improved fuel economy, flight deck systems, and passenger comfort features. Research is also being done on a lighter-than-air heavy lift vehicle [68.93].

These designs are driven by projections of market demand, and include systems driven by projections of air-traffic control capabilities. There are also design interactions with ground systems, pilot training and culture, emergency egress considerations, and so on. Given the uncertainty in how far and how quickly fuel prices will rise, how the demand for air service will change, and how technology (both flight deck and air traffic) will change, it is difficult to predict what vehicles will be present in the air-traffic systems decades from now.

However, research on the flight deck systems for those vehicles must commence now if they are to be ready for implementation when those vehicles undergo development. Fortunately, the principles of safety and efficiency will continue to drive the design of those systems.

68.4.3 Superdensity Operations

One of the major constraints on air-traffic growth is the airspace surrounding the airport, referred to as the terminal area. In the terminal area, the airspace is densely crowded with aircraft whose positions are changing in three dimensions, and whose rate of change of positions is also changing. This greatly complicates the task of pilots and controllers.

Tomorrow's air-traffic system is being developed to accommodate two to three times today's traffic level. This means even more dense terminal airspace. As yet, there is no consensus as to how that will be accomplished. One possibility is that some or all of the separation responsibility will be with the flight deck; this will necessitate new automation to identify and resolve conflicts, while displaying information on these conflicts and resolutions to the pilots.

In addition, pilots may be responsible for meeting times-to-cross at various points along their route. While current-generation FMS can accomplish this task, this ability is brittle and is not conveyed well to pilots. As this becomes a primary responsibility of pilots, this capability will have to be significantly enhanced.

Currently, efficient arrival procedures are being developed and tested at major airports across the globe. These procedures are designed to reduce fuel use, emissions, and noise simultaneously. Implementing such procedures in superdense airspace will require additional technologies (such as flight deck displays of traffic information, improved flight-deck-based conflict detection and resolution, and intent broadcasting) and more widespread use of existing technologies (such as the global positioning system and autopilots coupled with advanced flight management systems).

68.4.4 Integration

New systems will have to be integrated with ground-based air-traffic systems as well as with legacy equipment. Systems will also have to deal with a mix of equipped, partially equipped, and unequipped aircraft.

It seems unlikely, given the burden of certification, that completely new flight management system software will be developed. Instead, it is more likely that the new capabilities will be added on top of the old software with updated hardware. New automation will therefore have to interface with old software, which was designed for low-performance computing. In addition, many systems onboard aircraft are substantially unchanged from decades ago, and provide their input to flight deck computers. It is unlikely these systems will change either.

As new systems are developed, they are typically expensive to implement. Therefore, many manufacturers, airline companies, and individuals choose not to implement them. This creates complexity, not only for improving the system, but also for the use of flight deck systems. For example, the TCAS system must work not only between aircraft equipped with TCAS and mode S transponders, but with those equipped only with a basic transponder as well. This situation is likely to get worse before it gets better – as new technologies come into the market, there will be a wider disparity of capabilities across aircraft.

68.5 Conclusion

Modern flight decks contain a large number of automation systems, including control, warning, and information automation. Significant changes are being considered for air-traffic control systems, which will influence automation systems for flight decks and provide incredible opportunities for tomorrow's automation engineer. These changes will have to balance future needs, the increase in capabilities over the last few (and next few) decades, the expense of advanced automation, and the long lead times associated with the development and certification of flight deck automation.

69. Space and Exploration Automation

Edward Tunstel

Space-faring nations are actively exploring outer space and planetary bodies in our solar system both individually and as collaborators with other nations. In most endeavors, the inherent risk to human life has been mitigated by the use of automation and robotics to conduct space missions. Missions extending from low-Earth orbit to Earth's moon and beyond to destinations throughout the solar system have been successfully conducted. Robots and human astronauts assisted by automated systems have been used on space missions. Infrastructure and service automation in the context of space missions are discussed in this chapter. Automation and robotics have played a substantial role in installing space exploration infrastructure such as Earth-orbiting satellites and space stations occupied for extended periods by astronauts as well as satellites that operate for extended periods in orbit around other planets. General background information about automation and robotics for exploration of space is presented. Challenges of applying automation in space and planetary environments are highlighted for robots that operate in Earth orbit, at the Moon, at Mars, and other destinations. A look forward to what the future will hold for further space and exploration automation is provided, including mention of advancements in technological capabilities that will be needed to accomplish more ambitious space missions.

A wide variety of solutions to many problems in military and civil space programs are being addressed using some level of automation and robotics. Automation and robotics is personified by the synthesis and application of integrated electromechanical and computer systems that perform useful functions for engineering, science, or industrial applications. Space agencies around the world employ robotic systems instrumented with a variety of sensors and tools as surrogate explorers and automated workers on-orbit, as assistants to astronauts, on remote planetary surfaces, and throughout the solar system. Their systems and missions provide the infrastructure and service automation that enables access to space and planet destinations throughout our solar system.

Of particular relevance to automation for space exploration are sensing, perception, and control issues associated with operations in space environments and limited support from humans. These issues are relevant in the context of challenges associated with robotic tasks required for a variety of space missions. Some missions are purely focused on scientific discovery. Other missions may require building physical infrastructure for human activity in space. Still others may aim to provide sustenance for humans in eventual habitats away from Earth. In all such cases, sensing, perception, and control issues are relevant for automated and robotic solutions. Applications to future space missions will involve automated exploration, service, and construction tasks to be performed on orbiting space stations, in planetary atmospheres, as well as on and beneath planet surfaces.

Space robots are used to automate tasks in space environments when simpler or less expensive automation solutions are infeasible. The decision to employ robots to automate execution of certain tasks must consider task complexity, constraints of space environments, and an array of certain and potential risks involved. The required level of system autonomy may also dictate the applicability of automation and robotic solutions for use on space missions. Combinations and various levels of hardware, software, and control provided by humans are brought to bear to perform successful space missions. The relative allocation of task or mission functionality to hardware, software, and humans provides a sense for the degree of automation employed by a given system.

In the remainder of this chapter, space and exploration automation is discussed through the presentation of background thoughts about the field and challenges that define the complexity of space operations for automation and robotics as well as highlights of representative space robots and their applications. Some future directions and technological capabilities needed for future space missions are also noted.

69.1 Space Automation/Robotics Background

Automated systems and robots serve a variety of purposes in space environments whether sharing, augmenting, or extending human activity. Examples include transporting scientific instruments and equipment to space destinations for deployment and operation. They serve as substitutes for human presence in hostile space environments that are inaccessible to humans or difficult for humans to work safely and efficiently within. Like similar automation systems used on Earth, space automation and robotic systems are also useful for performing mundane or repetitive tasks that allow humans to focus on more deliberative, cognitive or otherwise complex tasks. Space automation and robotics also facilitates the creation, delivery, and operation of scientific, commercial, and military assets in space, thus enabling the existence and use of facilities that are unavailable or infeasible on Earth (e.g., space telescopes (Fig. 69.1), interplanetary probes, and space laboratories such as the International Space Station and the Russian Mir Space Station).

Fig. 69.1 The European Space Agency's (ESA) XMM-Newton is the most sensitive x-ray telescope ever built. Its high-technology design uses over 170 wafer-thin cylindrical mirrors spread over three telescopes. This unique x-ray observatory was launched by Ariane 5 from the European spaceport at Kourou in French Guiana on 10 December 1999 (courtesy of ESA)

Robotic space systems are typically supported by human and computer systems on Earth that facilitate their control and operation. Human mission controllers/operators on Earth utilize a comprehensive collection of computer systems, scientific data and information, and in particular software tools that aid decision making. This so-called ground data system represents the connectivity and flow of data and information on Earth as opposed to communication links between Earth and spacecraft in flight or at other planets. It encompasses networks of antennae used for continuous spacecraft tracking [such as the National Aeronautics and Space Administration (NASA) Deep Space Network – a worldwide spacecraft tracking facility managed and operated by NASA's Jet Propulsion Laboratory], facilities that provide communications between the antennae and the locations conducting mission control/operations activities, and a system of computers, software, networks, and procedures that process spacecraft data.

Robotic spacecraft share subsystems that serve or perform the following common functions [69.1–4]:

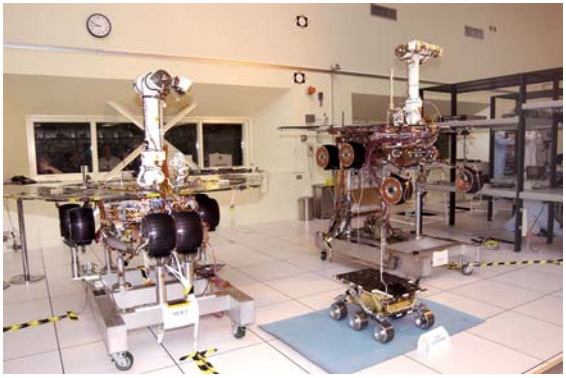

Fig. 69.2 The twin rovers of the Mars Exploration Rover Mission pose with their ground-breaking predecessor, the flight spare of the Sojourner rover from NASA's 1997 Pathfinder mission (courtesy of NASA Jet Propulsion Laboratory)

propulsion or locomotion, attitude control, power generation and distribution, structural integrity, thermal control, communications, command and data handling, and accommodation of mission-specific payloads. The command and data handling subsystem typically includes a programmable computer that enables automation of a variety of tasks. The types of robotic spacecraft employed in past and current space missions include flyby spacecraft, orbiter spacecraft, atmospheric probe spacecraft, penetrator spacecraft, lander and surface rover spacecraft (Fig. 69.2), observer spacecraft, and communications/navigation spacecraft. This classification is based primarily on functional spectrum of robotic spacecraft mission types. A subset of past and current spacecraft include or carry robotic mechanisms that interact physically with the target environment through manipulation or mobility such as wheeled or legged ground vehicles, and robots with manipulator arms and gripping end-effectors.

The current state of the art for space automation and robotics is limited by the rate of technology development, budgets for the same, and inherent conservatism in space mission risk management as it relates to automation. On-orbit tasks such as space structure assembly, inspection, and maintenance are presently limited to collaborative astronaut and telerobotic execution approaches. For the past two decades, the NASA Space Shuttle Orbiter with Canada's Remote Manipulator System (Canadarm) has assisted astronauts with successful on-orbit servicing tasks such as satellite retrieval, repair, and rescue. This includes servicing of the Hubble Space Telescope involving critical parts replacement and instrument upgrades (Fig. 69.3). The level and success of automation is increasing, however, with recent use of the Canadarm (with a boom that extends its reach) to assist with visual on-orbit inspection of heat shield tiles on the underside of the Space Shuttle Orbiter in 2006, and with a recent successful demonstration of autonomous on-orbit fuel and battery transfer from one spacecraft to another in 2007. The latter was performed by the Boeing Orbital Express system, which consists of an autonomous on-orbit servicing spacecraft and a serviceable client spacecraft. Surface rovers are reasonably advanced in autonomy but currently limited to autonomous traversal of hundreds of meters per day over relatively benign terrain.

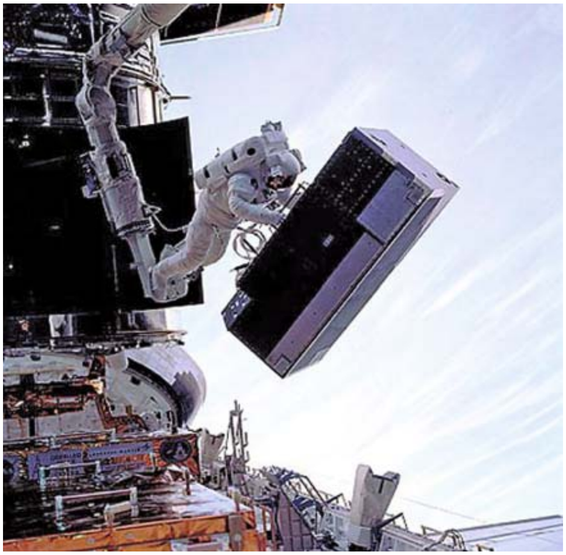

Fig. 69.3 Astronaut servicing the Hubble Space Telescope while secured by foot restraints to the end of the Canadarm (Space Shuttle Remote Manipulator System)

69.2 Challenges of Space Automation

Space systems are subject to strict limitations on power, communications, data processing, and hardware resources in general, not to mention mass and volume. Sensor devices and systems, in particular, must comply with certain specifications of size and payload capacity, onboard power availability, thermal limitations, and solar radiation tolerance. Such constraints are imposed by characteristics of the target space environment and mission objectives among other things, such as the rigors of space travel. In addition, electronics (including associated embedded computing) should be qualified to survive and operate within the harsh temperature and radiation extremes of outer space and similar extremes on planet surfaces with thin atmospheres (such as Mars). Mechanical assemblies and components with few or no moving parts are preferred since they stand a better chance of surviving the vibration and gravity forces of spacecraft launch, atmospheric entry, and landing associated with robotic flights from Earth to other planet surfaces. The nature of certain space missions or sheer distances to their destinations require robotic spacecraft to operate on their own for extended time frames without communication with human mission operators. Thus, certain levels of autonomy are required.

A fundamental challenge of robotic automation in space and on-orbit is the need to operate in microgravity wherein the effects of forces are quite different than in Earth gravity. Robotic operations in space are characterized by slow motions that facilitate compensation for undesired forces and moments due to microgravity. Robot manipulator arms and mechanisms typically utilize computer-vision-based perception, proximity sensors (based on infrared or electrical capacitance, for example), and force/torque sensors to achieve gross and fine manipulation. Dexterity for the latter is often enabled by additional mechanical degrees of freedom and/or advanced automatic control techniques. The same is true for manipulation mechanisms affixed to mobile robotic platforms.

Navigation by mobile robotic platforms, or rovers, on planet surfaces presents several challenges. Rovers must be able to detect hazards and assess the traversability of the terrain. Additional problems to be addressed for navigation include maintaining knowledge of rover pose (three-dimensional (3-D) position and 3-D orientation), as well as stability and traction as it traverses terrain or maps the local environment and prominent landmarks relevant to the mission. Sensing and perception for mobility and navigation are essential for missions requiring land reconnaissance or survey for the purpose of scientific exploration as well as for site construction and operations. A variety of sensors are commonly employed to measure rover motions, position with respect to the environment, and the presence of or range to mobility obstacles. Existing sensor types are as varied as the physical phenomena underlying their operation (e.g., optical, inertial, magnetic). Despite the large variety of available sensor technologies, planetary rover sensor systems are often restricted to few types due to limitations and/or constraints related to mass, volume, power, and operability/survivability in space environments; for example, on Earth, a common sensor for position estimation and localization is the satellite-based global positioning system (GPS), which provides accurate outdoor position knowledge in terrain where sufficient reception of signals from Earth satellites can be achieved. Orbiting satellites at Mars that have sensors of sufficient spatial resolution may be used to facilitate rover position, but no existing analogue to Earth's GPS is available at Mars yet. This is a major limiting factor of localization accuracy achievement for rover systems there. Robust surface navigation requires accurate heading measurement or very good heading estimation. Errors in heading estimates directly affect the accuracy of rover position estimates. Optical encoders, potentiometers, or resolvers are often used to measure revolutions of robot wheels. Such measurements allow heading and position estimation via dead reckoning or wheel odometry (based on the robot kinematics) relative to some known starting position and heading. However, in rough and rugged outdoor terrain these estimates are only reliable over short distances. Thus, for long-range traverses, more reliable heading information is required. To achieve this, Earth-based robots often employ magnetic devices, such as compasses, which provide good absolute heading measurements with respect to true north of Earth's magnetic field. Magnetic heading sensors are not as useful on Mars, however, due to the planet's negligible magnetic field.

Some of the key technical areas receiving focused attention by the space automation developers include: sensing and perception, robotics on-orbit, in-space, and subsurface as well as increased automation of space systems in general. Key points in each of these areas are discussed in turn below.

69.2.1 Sensing and Perception for Manipulation and Mobility

Modeling, simulating, and/or predicting the functional behavior of orbiter and flyby spacecraft is facilitated by reasonably well-behaved dynamics and operating environments. For such robotic spacecraft, conventional estimation and control techniques have similar effects on spacecraft behavior in simulation as they do in reality. This is due to the fact that the physical laws of orbital mechanics and planetary atmospheric aerodynamics are reasonably well understood and well behaved in space. For surface rovers, the interactions between their mobility systems and planet surfaces are complex and sometimes further complicated by reduced-gravity effects. The result is nondeterministic behavior as the system interacts with the world and increased uncertainty in how the autonomous mobility system will respond to operational commands. As such, mobility and navigation problems for rovers are characterized by high levels of difficulty and increased measurement uncertainty. Common mobility and navigation sensors often inadequately handle the tremendous variability of surface features and properties of natural terrain. Advanced sensing and perception techniques are often required for detection or measurement of significant wheel–terrain interactions such as slippage and sinkage, and assessment or measurement of certain terrain properties prior to engagement by the rover.

Robotic Manipulation

Mechanical manipulators or arms with multiple degrees of freedom are useful on a variety of robots operating in space, on-orbit, and on planet surfaces. They include fixed-base manipulators on space shuttles, space stations, landers, and rovers as well as manipulation appendages on free-flying robots. Robotic tasks for this variety of systems may require fine positioning and dexterous manipulation of equipment or the environment. In order to accomplish manipulation tasks, robots typically execute closed-loop feedback control of arms/mechanisms, with the essential feedback provided by appropriate sensors. Further considerations for achieving reliable manipulation include avoiding collisions of the manipulator with the robot itself, avoiding unintended contact with the environment, and controlling forces during intended contact with the environment. Oftentimes, it is also necessary to compensate for errors associated with degradations and/or changes in the manipulator hardware due to environmental factors such as spacecraft launch/landing vibrations and material thermal expansion, which can affect the ability to accurately position a manipulator at a target of interest. Sensing solutions that provide adequate coverage and resolution for both gross and fine manipulation are essential for missions requiring object handling and transport, servicing/repair, assembly/disassembly, sample acquisition, and in situ acquisition of scientific measurements. Additional information on robotic manipulation, and automation mobility and navigation can be found in Chap. 16.

Wheel Slip and Sinkage

Wheeled mobility systems are subject to undesirable wheel–terrain interactions that cause wheels to slip on rocks and soil. Frequent loss of traction due to wheel slip during traverses from one place to another will detract significantly from the ability to maintain good rover position estimates. Computer-vision-based motion and pose estimation, or visual odometry, is one viable sensing solution. Current methods require substantial computation but may be feasible for future, relatively fast-moving rovers if realized in hardware or firmware with cameras that have dedicated embedded processors.

It is highly desirable to have a capability to sense wheel slippage so that corrective control actions may be taken. Barring the capability to directly measure wheel slip, measurement of over-the-ground rover speed would allow calculation of percentage slip using an analytical relationship between slip, over-the-ground speed, and wheel linear speed (as derived from encoder readings or tachometers, for example). The problem here is that true over-the-ground speed is also difficult to measure. If a rover attempts to drive forward while all wheels are slipping, interpretation of wheel encoder readings alone will indicate forward progress, but in all probability the rover position will not have changed significantly. Some Doppler and millimeter-wave radar solutions exist for measuring true vehicle speed, but for rover use they must be low-power and low-mass devices.

In soft soils, loss of traction due to excessive wheel slippage can also lead to wheel sinkage and ultimately vehicle entrapment. It is possible for wheels to sink to soil depths sufficient to prohibit rover progress over terrain, thus trapping the vehicle at one location. This is also possible on soils with insufficient bearing strength to support the rover (incidentally, a property to which a look-ahead visual perception system may be insensitive). Like wheel slip, it is desirable to have a capability to sense excessive wheel sinkage so that corrective controls may be executed before immobility results. Sinkage measurements are also valuable for reducing position estimation errors. A means to measure wheel sinkage permits overall reductions in the effects of propagating nonsystematic error during rover traverses on varied terrain.

Terrain Properties

Capabilities for noncontact sensing of terrain properties such as hardness or bearing strength are needed for detecting nongeometric mobility hazards. Passive stereo vision or other ranging systems available on existing rovers cannot detect pits filled with loose drift material that may have insufficient load-bearing strength to support a rover. Such hazards are known to exist on the Martian surface and need to be detected before a rover engages them, potentially meeting with catastrophe. Downward-looking impulse radar can be employed as a proximity sensor for this problem. Similar millimeter-wave and microwave ranging sensors are also useful for general obstacle detection and collision avoidance in environments subject to dust, blowing sand, and other all-weather conditions. However, the mass of available units may be prohibitive for some planetary rover applications, and like the speed measurement radars mentioned above, candidate radars for terrain property sensing must be low-power and low-mass devices.

It is also possible to infer nongeometric terrain properties from sensor data. Some viable approaches consider terrain appearance in camera images using image texture differences for soil and rocks and other approaches employ proprioceptive sensing (e.g., of vibrations) to resolve differences in *feel* of the terrain type beneath rover wheels. The latter approach applies once the terrain in question has been engaged and is therefore more useful for intelligent, reactive traction control than for nongeometric mobility hazard avoidance. The look-ahead, image texture-based methods, in addition to their utility for appearance-based hazard detection, are also useful for intelligent predictive traction control on varied, but traversable, terrain surfaces.

69.2.2 On-Orbit and In-Space Robotics

Space robots have been used in low-Earth orbit for tasks of automated servicing, inspection, and assembly. Satellites require servicing for various reasons, each calling for various forms of service action to be taken. Failure of defective hardware may call for repair or replacement of components or modules. Anticipated depletion of fuel or propellant may call for refueling in space if the satellite's mission is intended to continue. When a satellite's lifetime or mission expires it may be necessary to remove it from orbit. On-orbit robotic servicing applies to repair/replacement and refueling activities.

One of the automation challenges is the physical capture of free-floating satellites for retrieval and subsequent servicing. Other challenges are related to the general area of intelligent sensing and associated data processing to ensure safe operations. Servicing activities are representative of maintenance tasks that are slated for on-orbit and in-space robots (Fig. 69.4). Other relevant tasks fall into the categories of assembly of space structures and their post-assembly inspection (Fig. 69.5), as well as assistance to astronauts performing extravehicular activity (EVA).

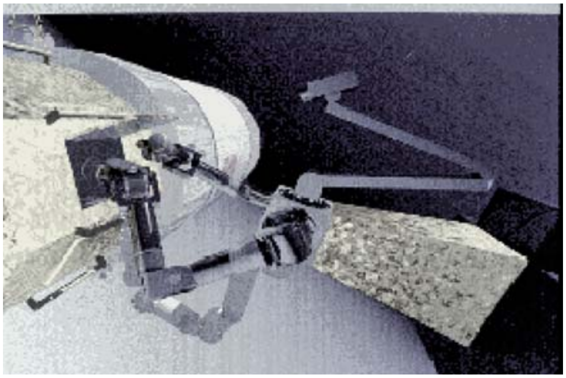

Fig. 69.4 Illustration of robotic maintenance in space

In assembly operations, space robots would be used to transport structural elements and mate elements that are part of a larger space structure. Such tasks call for rendezvous and docking, dexterous manipulation, and fine motion control for execution of detailed assembly sequences. In-space assembly may be supported by automated planning on space robot computers and on off-board computers, or via human teleoperation. Some space structures will have dedicated robotic systems as part of their fully assembled design. An example is the International Space Station, which (when fully assembled) will have robotic systems including three main manipulators, two small dexterous arms, and a mobile base/transporter system.

Robots that perform important inspection tasks are also needed on-orbit to examine space station and

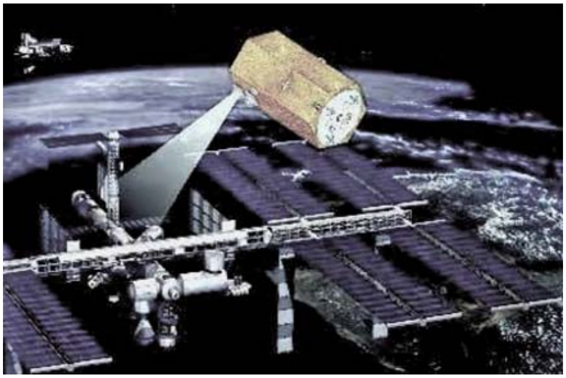

Fig. 69.5 Illustration of robotic inspection in space

spacecraft external hardware and outer surfaces for damage or other problems. This may be done using robotic vision supported by mobility algorithms designed to ensure required coverage of critical surfaces. Both free-flying and legged space robots that walk on space structure exteriors can be employed. When astronauts must leave the safer confines of space stations or spacecraft to perform EVA, space robots will support their activities by performing tasks such as retrieval and hand-off of tools for astronaut use, monitoring of EVA operations, serving as additional eyes or illumination sources to facilitate EVA in areas that are hard to access, or working cooperatively as direct EVA participants. Research is underway to address necessary challenges and technology developments applicable to a range of system entities from Earth-based operations infrastructures to autonomous robotic operations.

69.2.3 Subsurface Robotics

The solar system exploration agenda for the world's space agencies includes plans to access and sample the subsurface environments of terrestrial planets, moons, and small bodies such as comets and asteroids. This will be yet another class of tasks for space robots. Near-term focus is on the Moon, Mars, and Jupiter's moon Europa, the surface of which is ice-covered and the subsurface of which is presumed to be an ocean of water possibly harboring life. The subsurface of Mars is of interest because it is believed to be the only place on the planet in which liquid water potentially exists and because its sedimentary rock layers are believed to contain information about the geologic, hydrologic, and climatic evolution of the planet as well as any signs of extinct life (Fig. 69.6). Subsurface water in its various forms on Mars is also considered a critical resource for sustaining robotic outposts and future human explorers. Water-ice and structure of the lunar subsurface are of interest for similar reasons. Along the same vein, the potential for an ocean and life on Europa make its scientific interest quite clear.

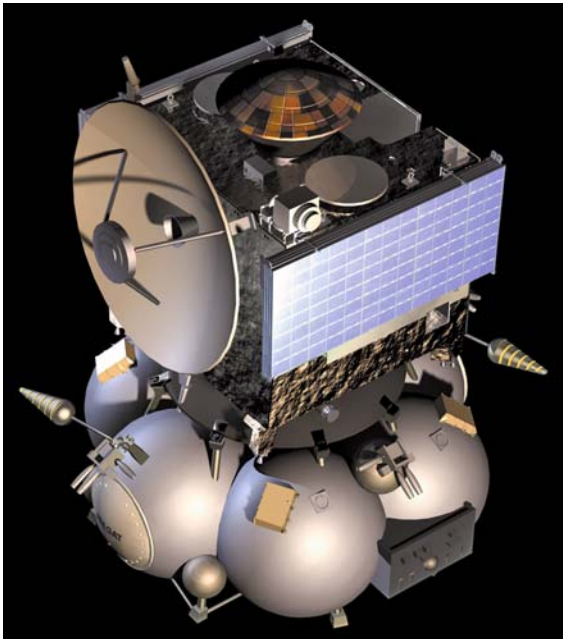

Fig. 69.6 Mars Express spacecraft (courtesy of ESA)

Today there is significant focus on ways and means to drill and bore into the surfaces of these bodies using automation and robotics, and there are many challenges to overcome. Most challenges being addressed presently relate to understanding the physics and mechanical system requirements for drilling into consolidated and unconsolidated materials comprised of soil, rock, and/or ice to both shallow and deep depths. Based on the findings of various such studies, associated requirements for intelligent control and autonomy for robotic subsurface explorers are being pondered as well by planetary scientists and engineers alike (including aerospace, robotics, and Earth mining engineers).

Robotics challenges presented by drilling mechanics largely relate to control issues. After years of experience drilling into the Earth, the best techniques are still more of an art form than an engineering procedure. Humans are typically intimately involved in determining and implementing the recovery procedures when problems occur that inhibit drilling progress. The art form mastered by human drill operators translates, for space robotics, into a sensor-feedback-intensive, knowledge-based, and reactive control task that will need to be fully autonomous since similar levels of human supervision will not be possible on remote surface missions. Robust capabilities of automated monitoring and diagnosis with safe and reliable autorecovery algorithms are necessary. At the very least, human-equivalent performance by robotic subsurface devices may be needed for most tasks. As with subsurface drilling on the Moon or Mars, locomotion through ice followed by subsea navigation will require high levels of robotic autonomy moving beyond intelligent control and onto adaptive and learning systems.

69.2.4 Automation

Robotics typically refers to electromechanical systems that embody some level of programmable intelligence and that interact with or within physical environments. Robots often operate in environments that are largely unknown a priori and may be unstructured, thereby requiring sensing and perception to compute or infer intelligent actions. Automation often refers to automated devices or techniques that somehow improve the performance or utility of a system or process. Automated systems often operate in structured environments, and their operation may or may not be physical.

Automation for space systems is often applied to reduce costs or enable new mission capabilities. To date, some of the most advanced examples center on the use of robotics as the form of automation, as nonrobotic human spaceflight missions have relied to a large extent on the capabilities of humans to achieve mission success. Automation has also been used for more common actions such as spacecraft antenna and solar panel deployment enabled by automatic mechanisms and devices. In the present and future, the use of nonrobotic automation is on the rise and comes in a variety of forms. Applications range from more pervasive software-based automation of data processing functions to incorporation of robotic capabilities into space suits intended to augment and amplify human capabilities in space. On some space missions, collection of scientific data as well as its processing and analysis is also handled by automation of science instrument systems. Some of the means of automating such functions include computer vision, pattern recognition and classification techniques, and automated reasoning methods of artificial intelligence.

Other activities and required infrastructure for future space missions call for automation of the manufacturing and construction variety. This is the case for outposts on other planetary surfaces or in space where humans would live and work for extended periods. Astronauts living and working in space on space stations are typically surrounded by automated systems that run life-support systems and perform functions formerly performed by themselves or their human mission controllers based on Earth. Example tasks for space station automation solutions include initiation and monitoring of experiments as well as detection and diagnosis of system failures. On planetary surfaces, the cost-effective approach to sustenance of astronauts includes living off the land by using in situ resources; for example, automated systems and production plants would collect and process soil to extract water. Outpost automation would manufacture materials needed for life support systems and would produce electricity and fuels to power equipment and facilities. Implementation of automated systems along these lines has been contemplated and extensively studied for many years [69.5] and will be essential for long-duration human presence in space.

69.3 Past and Present Space Robots and Applications

Over the past 30 years, the exploration activities of international space agencies have given automation technology a proving ground for demonstrating its utility and practicality in space. In the 1970s the former USSR landed rovers on the Moon and teleoperated them from Earth (Fig. 69.7). Since the early 1980s numerous NASA space shuttle flights have consistently involved teleoperation of the Canadarm. Space structure and scientific hardware deployments, assembly, servicing, and repair have been some of the primary uses of space automation on such missions in low-Earth orbit. Such on-orbit uses of automation and robotics have involved performance of tasks by astronauts and robots teleoperated by astronauts, with the most complex work performed by suited astronauts during EVA, that is, on *spacewalks* outside of the Space Shuttle Orbiter. Other robotic systems have been used in this general class of application scenarios for tasks associated with automation of science experiments performed in space-based laboratories. In the early 1990s, Germany's ROTEX technology experiment demonstrated the use of a mechanical manipulator remotely controlled from Earth while on the NASA Space Shuttle Orbiter as well as remotely controlled by astronauts on the Space Shuttle Orbiter. Japan's Experimental Test Satellite VII demonstrated automation and robotic servicing technologies on-orbit in the late 1990s. NASA's free-flying Autonomous Extravehicular Robotic Camera demonstrated a means to provide additional viewpoints or *eyes* for astronauts during EVAs. Additional systems have been proposed and developed for space automation but never flown for various

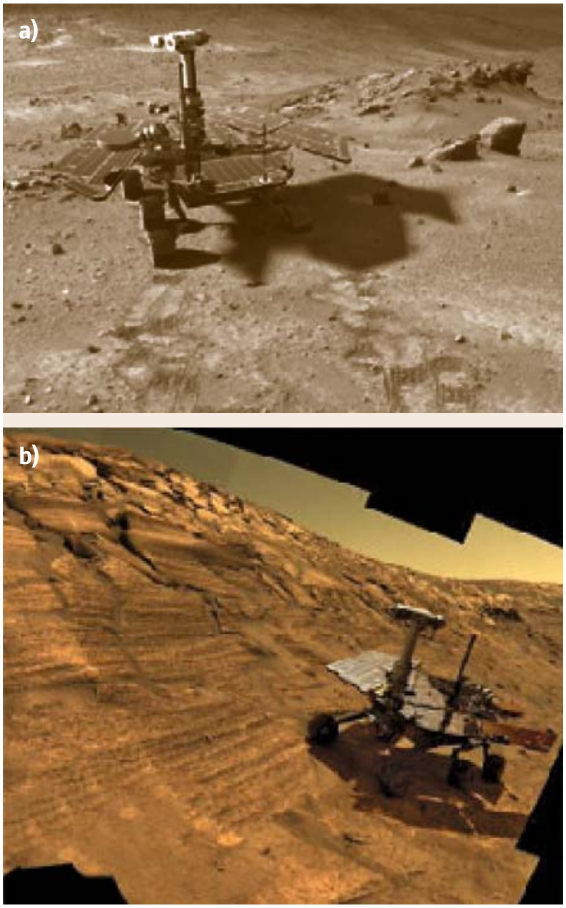

Fig. 69.9a,b Mars exploration rovers Spirit **(a)** and Opportunity **(b)** on Mars (special-effects images created using photorealistic rover models and image mosaics acquired during their missions)

reasons such as budget-related cancelations (e.g., the Orbital Maneuvering Vehicle, the Flight Telerobotic Servicer, and Ranger).

With the exception of the Moon missions of the 1970s the aforementioned automation and robotics activities have been performed in low-Earth orbit. Space automation has been applied in geostationary orbit around the Earth as well. The many communications, scientific, and military satellites in various Earth orbits today are great examples of space automation that have directly affected quality of life on Earth. Robotic tasks that can be automated in geostationary orbit include satellite servicing and deployment/assembly of large space structures. However, since astronauts have, to date, been constrained by technology to operations in low-Earth orbit, robotic systems are more critical for automated activities in geostationary orbit.

Moving further out into space beyond Earth, robotics continues to play a critical role in expanding our knowledge of the solar system. Space agencies have employed numerous interplanetary robotic spacecraft, planetary probes, surface landers, and rovers that have collected a substantial amount of data leading to our current understanding of the solar system [69.6]. Destinations visited include nearly all of the planets as well as asteroids and comets. The use of robotic technology in space has reached a level where, presently, multiple robotic spacecraft are operating at any given time throughout the solar system. At Mars alone, multiple robotic spacecraft including satellites, landers, and rovers are in operation today, performing scientific missions aimed at understanding the past or present habitability of that planet. The most recent orbiting spacecraft that are still in operation at Mars were delivered by the USA and Europe and include Mars Odyssey, Mars Reconnaissance Orbiter (Fig. 69.8), and Mars Express (Fig. 69.6). The most recent rovers that are still in operation are NASA's twin Mars exploration rovers, Spirit and Opportunity (Fig. 69.9), which have been operating at different locations on the Martian surface since 2004. They have both collected data leading scientists to conclude that liquid water once flowed on the surface of Mars at their respective landing sites.

69.4 Future Directions and Capability Needs

Relatively few places on Earth's moon have been explored by the rovers of the 1970s and by astronauts during the series of NASA Apollo missions. As such, relatively little is known about our Moon. Today, the world's space agencies and commercial sectors are turning a renewed focus on the Moon for further scientific exploration, lunar resource-related commercial industry, space tourism, and as a proving ground for enabling future human exploration of Mars. Automation and robotics are pervasive as tools to be used by human explorers to perform a variety of tasks involving rovers and automated equipment for:

- Surface exploration and transportation/deployment of instruments and systems
- Acquisition of scientific samples
- Industrial mining for resources
- Moonbase construction and assembly of facilities
- Overall maintenance and repair of lunar infrastructure.

On the lunar surface, networked teams of robots will work cooperatively to prepare sites for human habitats at permanent lunar settlements. Robots will work with automated machines and instruments as an integrated system that constructs, services, monitors, and repairs lunar outpost facilities. Such tasks may be shared with astronauts or lunar settlers. Robotic systems will also help to automate prospecting, mining, and processing of lunar raw materials to help sustain human presence by minimizing dependence on Earth support. Automation and robotic technologies to be developed toward this end will be used in similar ways to facilitate eventual human exploration and settlement of locations on Mars.

In space, free-flying space robots will advance beyond the current state of the art to perform routine servicing of space assets such as Earth satellites and space stations (Fig. 69.10). Free-flying robots will work cooperatively with astronauts to construct large scientific and engineering space structures. Advances in the following areas will be needed:

- Mobility on space structures
- Rendezvous and docking with spacecraft and structures

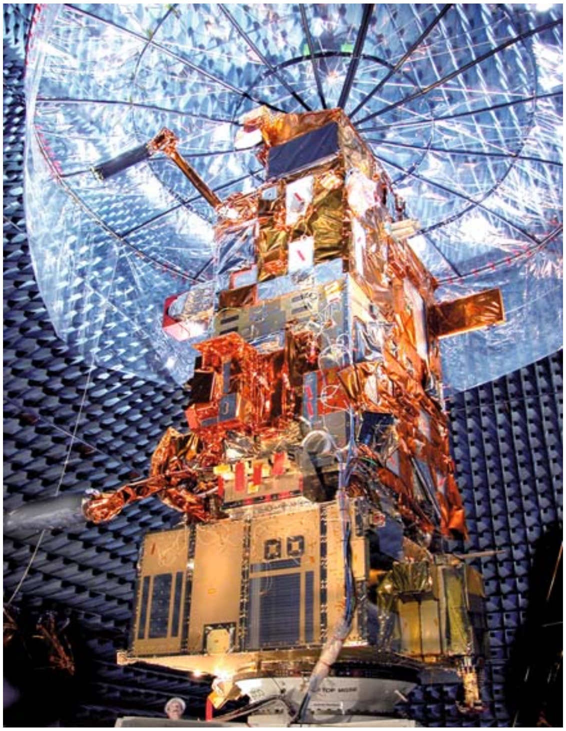

Fig. 69.10 MetOp-A satellite undergoing final testing at EADS Astrium's facilities in Toulouse. MetOp-A was launched on 19 October 2006 from the Baikonur Cosmodrome in Kazakhstan, on a Soyuz ST rocket with a Fregat upper stage (courtesy of ESA)

- Dexterous and force-controlled object grasping, manipulation, and transport
- Human–robot task planning and sequencing.

Planetary surface robotic systems will advance to the next level of autonomous capability enabled by new and improved sensing solutions. Advances are required to reduce the computational complexity of computer vision algorithms or to increase the computational speed of radiation-hardened processors that they run on. In addition to devices for sensing or detecting wheel slip, wheel sinkage, and terrain properties for planetary surface mobility, reliable devices and software are needed that improve existing capabilities for:

- Sensing large-scale terrain discontinuities such as cliffs, craters, and escarpments
- Optical ranging in both full sun and deep shadow
- Distributed sensing in multiple-rover applications.

69.5 Summary and Conclusion

An overview of space and exploration automation and various associated challenges was presented with relevance to robotics applications for on-orbit, in-space, and planetary domains. Representative space robots and applications were noted followed by indications of future directions for space automation and technological capabilities that will be needed to successfully perform future space missions.

During the past several decades space automation has been relied upon, either solely or in concert with resident human capability, to explore and reveal scientific knowledge of space and the planets. The levels of automation or degrees of autonomy have varied from mission to mission and will necessarily increase in the future as more ambitious space missions are pursued.

Autonomous mobility and manipulation are fundamental functions for space robotic tasks. Viable solutions that support these functions within formidable constraints of space computing hardware drive the technological capabilities of space robots, and ultimately, mission success. Application domains include planetary surfaces, outposts/settlements, on-orbit/in-space operations, and subsurface environments. The challenges are associated with robotic tasks including exploration, servicing, infrastructure building and construction, inspection, and assembly in space and planetary environments. A sense of the existing levels of automation and the robotic intelligence or autonomy employed to meet the various challenges is provided.

In general, automation and robotics for space and planetary missions require a variety of mobility and manipulation capabilities supported by viable and adequate means for sensing/perception and sophisticated software algorithms that represent an appropriate level of intelligence for the mission. Solutions must comply with hard constraints on mass, power, mechanical complexity, electrical characteristics, and computing. In time, the greatest needs and remaining limitations will be addressed and overcome by innovations and advances in sensing, perception, and autonomous control engineering. To be sure, space robot intelligence and autonomy will play a critical role in meeting the challenges to come.

70. Cleaning Automation

Norbert Elkmann, Justus Hortig, Markus Fritzsche

The potential applications of automation for cleaning are many and diverse. All over the world, research organizations and companies are developing automatic cleaning systems [70.1]. Products such as automatic floor cleaning robots and floor vacuum cleaners available for household use are sold ten thousand times over every year at prices below US $300 (Fig. 70.1). While versatile, high-performance systems exist for other applications such as professional floor cleaning, airplane washing, ship cleaning, and facade cleaning, they are by no means as widespread as household systems.

Automatic cleaning systems are frequently extremely complex robot systems that operate autonomously in unstructured environments or outdoor areas. Cleaning automation not only incorporates cleaning engineering but also a variety of other technical disciplines, e.g., autonomous power supply, sensor systems, environment modeling, and path planning in dynamic environments.

Some examples of automatic cleaning systems for floors, facades, swimming pools, ventilation ducts, and sewer lines serve to highlight the current potential of cleaning automation and provide a glimpse of future developments.

Humans typically experience cleaning as monotonous work, which by its very nature is performed in *dirty environments*. Moreover, cleaning can sometimes even be hazardous to health or life endangering, depending on the area or object and the type of cleaning involved. Nonetheless, such areas may require regular cleaning.

Cleaning therefore ideally meets the premises for applying robots or remote-controlled systems and is inherently a typical service robot application. Unsurprisingly, developments over the last 20 years have been aimed at automating cleaning systems. The range of systems available varies widely. Apart from floor cleaning systems, other systems also clean facades, swimming pools, ventilation ducts, and sewer lines. Some of them are extremely complex.

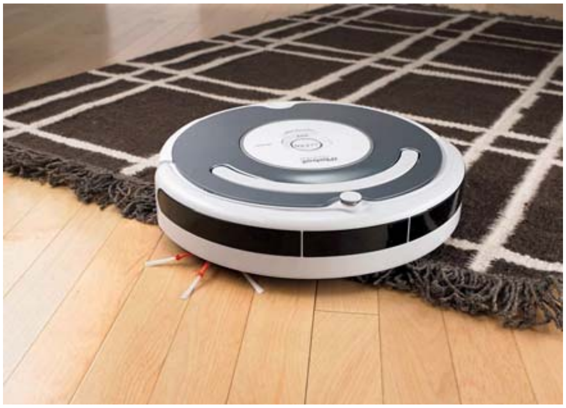

Fig. 70.1 iRobot Roomba

Mass markets for cleaning robot applications have already developed in some sectors. Vacuuming robots for household use represent one of the most widely sold robot systems worldwide. Their sheer numbers and low purchase prices of less than US $300 account for their great commercial success in the household sector [70.2, 3]. Residential users have far lower demands on cleaning quality and, above all, cleaning speed than professional users. In the 1990s, several manufactures of cleaning machines throughout the world developed autonomous cleaning robots for professional floor cleaning. Nonetheless, these systems have not yet become established on the market for a variety of reasons. Less flexibility than humans, high acquisition costs, low availability, and complexity of operation often militate against the use of these systems.

Cleaning robots [70.1] and floor cleaning systems (Fig. 70.1) in particular share many commonalities with other service robots, e.g., for transport or monitoring tasks. Particular points of intersection are sensor systems for obstacle detection and environment modeling, power supply, path planning and execution, and human–machine interfaces. Thus, cleaning robots constitute a preliminary stage to complex household applications for service robots or applications with direct *human–robot interaction*.

Cleaning robots for facades, pipes, ventilation ducts, and sewer lines are however not mass-produced items. These systems are specially optimized for the requirements and geometry of the surface or object being cleaned and are used exclusively in professional environments rather than in the residential sector.

A robot's features or technical innovations are less crucial to its acceptance than its cleaning efficiency and cost effectiveness. A system's flexibility and ease of operation are other important criteria for acceptance.

70.1 Background and Cleaning Automation Theory

Cleaning robots incorporate a multitude of basic developments and theories of robotics, e.g., mobility and navigation, communication, sensors and sensor networks, robotics and intelligent machines, and teleoperation, which are treated in conjunction with mobile robots in Chaps. 9 and 11 of this Handbook.

Cleaning robots have different levels of automation, ranging from *remote-controlled systems* with inexpensive, individual sensors to *autonomous systems* with complex, multiple sensors for environment modeling and navigation.

All types of cleaning systems share certain technical subsystems:

- Motion platform for the system and cleaning unit
- Control and operating system
- Sensor system for environment modeling (in automatic systems) and obstacle detection
- Power supply
- Communications system
- Cleaning unit and, where applicable, suction and material processing units
- Various safety devices (collision avoidance systems for floor cleaning systems, securing or recovery ropes for facade, pipe, duct, sewer, and pool cleaning systems)

All automated cleaning systems draw on established cleaning methods and technologies. An automated cleaning system however cannot inspect its *cleaning quality* as easily as a human can. At present, mobile systems that clean areas with varying optical conditions and textures cannot measure the level of dirtiness reliably. They can, however, check the quantity of dirt picked up over a unit of time.

Cleaning robots from the different fields of application differ widely in terms of requirements and technical challenges. Basically, two categories can be distinguished and the underlying requirements subsumed in these two groups:

- *Floor cleaning robots*: Such cleaning systems relieve humans of monotonous work such as mopping and vacuuming. For their use to be cost effective, these systems must function autonomously and without an operator. Easy operability, high-quality cleaning, and flexible use are basic requirements these systems have to meet.
- *Facade, pool, ventilation duct, and sewer line cleaning robots*: Such cleaning systems are utilized where humans are unable to access an area in need of cleaning or are only able to access it with extreme difficulty. These systems can be engineered to be remote controlled or fully autonomous. Usually, they are customized for a specific application scenario. Nevertheless, easy operability and high-quality cleaning are basic requirements. They must

also be recoverable when cleaning areas that are inaccessible to humans.

Significant features of these two groups of cleaning robots are highlighted below.

70.1.1 Floor Cleaning Robots

Without exception, floor cleaning systems utilize wheel-driven mobile platforms. The configuration of the wheels varies depending on the case of application and the maneuverability requirements. Kinematics with two driven wheels and other caster wheels are often used.

Sensor systems for *obstacle detection* and navigation vary widely. Inexpensive infrared or ultrasonic sensors and contact switches are employed in systems for household use. The sensor data generated does not provide a basis for optimized path planning in an environment and such systems normally change their direction of travel according to a given algorithm intended to optimally cover a surface. It can be assumed that the entire area has been negotiated and cleaned after an appropriate period of operation.

Floor cleaning systems for professional use predominantly contain laser scanners to generate maps and navigate. In this case, path planning and execution must be optimized to clean a maximum surface area within a specific time. Ultrasonic sensors and contact switches are often employed additionally as collision sensors. Objects such as walls, shelves or the like are particularly challenging when cleaning. On the one hand, safeguards are needed to prevent people from getting pinned, for instance, between the cleaning system and a wall. On the other hand, laser scanners' capability to generate precise maps near a shelf is limited. Batteries supply floor cleaning systems their power. To be cost effective, a floor cleaning system must be usable over several hours. The several hours presently required to charge a battery may hinder professional use. Floor cleaning systems must furthermore be equipped with efficient cleaning systems.

70.1.2 Facade, Pool, Ventilation Duct, and Sewer Line Cleaning Robots

Unlike floor cleaning robots that are normally used on level ground and equipped with batteries, dust reservoirs, and water tanks, other cleaning systems for facades, pools, pipes, sewers, and ducts must be supplied power through cables and cleaning medium through hoses and, where necessary, must have a fall arrester system or a recovery rope. The engineering and money required to implement these essential components, which constitute an indispensable infrastructure, are quite substantial compared with floor cleaning systems.

The use of cleaning robots on facades, in pools, pipes, ducts, and sewer lines may require their adaptation to ambient conditions that are highly unusual for automated systems and to environments that are less than ideal for robots. Variable ambient conditions such as humidity, temperature, and light conditions place great demands on components and, for example, necessitate adapting and increasing the redundancy of sensor systems for navigation. Given the high expectations on system reliability, this is particularly important.

Facade Cleaning Robots

Facade cleaning robots are often remote-controlled systems that clean surfaces that are inaccessible to humans or accessible only with great effort. However, isolated fully automatic systems that operate without human supervision are also in use, particularly in Europe. Some of these systems were designed specifically for a building during its planning phase. Remote-controlled systems in particular are designed to be universal and usable on a variety of buildings including their infrastructures without structural modifications.

Facade cleaning *robots* come in many different designs: *wheel-driven* systems for flat and slightly inclined glass roofs, *climbing* systems with vacuum cups for sharply inclined and vertical facades, and *rail-guided systems*. As a rule, facade cleaning robots must be able to navigate obstacles such as window framework and other facade elements. The use of sensors to determine position constitutes a particular challenge since they must deliver reliable data under the widest variety of outdoor weather conditions from rain to sunshine. All the facade cleaning robots in operation today have cables that supply electrical power and, depending on the system, compressed air, water, and data communications. There are no known systems that operate autonomously on facades without an *umbilical*. What is more, measures often have to be taken to secure a robot against falling [70.4]. Such measures have to be integrated into the overall concept and, where necessary, automated for fully automatic systems.

Pool Cleaning Robots

Pool cleaning robots have been in use for some 20 years to clean the bottoms and sides of swimming pools. The various manufacturers' products function on the basis of the same system. A tracked vehicle provides locomotion under water. Rotating brushes mounted on the front and back of the unit loosen dirt, which is then suctioned into a slot on the unit's underside and pumped through a filter. The water intake on the underside additionally increases the contact pressure, thus facilitating controlled movement on the vertical sides of pools.

Pool cleaning robots use a minimum number of sensors to orient themselves and move underwater completely independently. Since pool geometries are usually simple, navigation logic can also be kept simple. Simple sensor arrays on the fronts and backs of these systems are the elements of an efficient cleaning strategy.

Pool cleaning robots must be lightweight to make operator handling easy and to attain sufficient buoyancy for retrieval. Hence, battery operation is often not an option since it would not allow the necessary cleaning performance. Such systems are supplied with power through a cable with which they can be retrieved in the event of damage.

Ventilation Duct and Sewer Line Cleaning Robots

Cleaning systems for pipes, sewers, and ducts represent a sizeable market since their inaccessibility often prevents humans from being able to clean them without cleaning automation. Pipe and ventilation duct diameters are too small or areas may be hazardous to health or potentially explosive, e.g., in the petroleum industry or sewage disposal.

Thousands of different systems for pipe, ducts, and sewer line cleaning exist all over the world. As a rule, they are remote controlled or semiautomatic and move on wheels or tracks. They normally do not navigate autonomously and incorporate video cameras to display their environment to the operator. A cable connects these systems to a supply and control station. While this limits the systems' radius of action, it assures they are highly reliable, are supplied cleaning medium and can be recovered from pipes, sewers, and ducts with certainty. Cleaning methods vary widely depending on the case of application and include brushes, water, high water pressure, and dry ice.

70.2 Examples of Application

The automatic systems presented here are established systems that have achieved product maturity and, for the most part, been in operation for years. In addition to special applications for which very few systems are available worldwide, there are also applications for which a mass market has already opened. Accordingly, the systems cited here merely represent a few examples of the wide range of cleaning automation products. Space constraints only allow the description of cleaning systems presently in operation and preclude covering the multitude of prototype developments and experimental models.

70.2.1 Floor Cleaning Systems

A distinction must be made between professional and household floor cleaning systems as well as the types of cleaning, i. e., vacuuming and wet cleaning. The Hefter ST82 R floor washing robot is an example of professional wet cleaning, and iRobot's Roomba of household vacuuming. While the technical configuration and performance of other manufacturer's systems differ, the basic concept is comparable.

ST82 R Floor Washing Robot

Manufacturer:	HEFTER Cleantech GmbH, Germany
Type:	Professional floor cleaning system
Operating mode:	Autonomous, taught path
Cleaning technology:	Wet cleaning
Area of application:	Supermarkets, airports, large halls, etc.

Based on a standard floor cleaning system, the Hefter ST82 R floor washing robot is intended for professional cleaning of hard floors (Fig. 70.2). Outfitted with auxiliary localization and collision avoidance sensor systems, a navigation system and an onboard computer, the Hefter ST82 R is able to follow and effectively clean a programmed path fully autonomously and independently of an operator [70.5].

This cleaning robot can run in two operating modes: manual and automatic. In manual mode, the system performs like a hand-guided floor cleaning system in order to teach it the path to be cleaned autonomously and to recover it in the event it malfunctions.

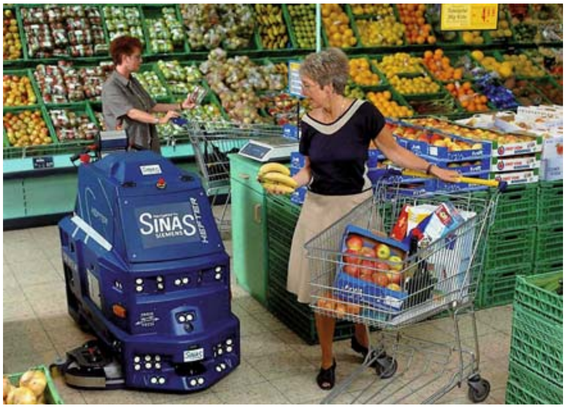

Fig. 70.2 Hefter cleaning robot ST82R

Automatic mode is programmed in two stages. The robot's entire work space is first navigated in manual mode. The robot's onboard navigation software automatically generates a virtual map of the workspace from the data collected by an odometer, a gyrocompass, ultrasonic sensors, and laser scanners during the first reference run.

A second reference run is taken afterward. This time, the intended cleaning route is followed exactly. A cleaning path based on the sensor data is entered into the virtual map. A Siemens SINAS navigation system furnishes the necessary navigation intelligence [70.6].

Once the reference runs have been completed, the cleaning robot is able to navigate the programmed path on its own. To do so, the robot is switched to automatic mode. The operator can no longer intervene in the robot's movement in automatic mode.

Since the robot moves in peopled surroundings, a multitude of safety mechanisms that prevent collisions with and injuries to people have been provided.

Along with switching strips mounted all over the robot, a laser scanner installed in the front skirt is an integral element of the safety concept. If one of the *safety* systems is activated, the robot initially reacts by moving to evade the direction of the source of activation. If this does not cancel the activated safety system, then an emergency stop is triggered. Automatic operation can be resumed only after acknowledgement by an authorized operator.

In hazardous situations the safety system is unable to detect, automatic operation can be interrupted by activating *emergency stop* buttons on the robot.

The Hefter ST82 R floor washing robot system was successfully tested in various retail stores but is no longer available for purchase.

Floor cleaning robots from other manufacturers include:

- The Hako Acromatic is for autonomous professional cleaning in buildings (but is no longer sold) [70.7].
- Fuji Heavy Industries' Subaru RFS1 is the successor to an autonomous floor cleaner sold since 2000. The latest model communicates with the elevator and can thus move independently from floor to floor. It is not designed for manual operation [70.8].

Other systems that at least deserve brief mention are the Comac CLEAN [70.9], Cybernetix Auror and Baror [70.10], Thomson Abilix 500 [70.3], Servus Robots [70.11], CleanFix Robo40 [70.12], Floorbotics [70.13], Robosoft AutoVac C6 and C100 [70.14], and VonSchrader Dolphin [70.15], AUTOMAX AXV-01 [70.16].

Roomba 500 Series Vacuum Cleaning Robot

Manufacturer:	iRobot Corporation, USA
Type:	Household vacuum cleaning system
Operating mode:	Autonomous
Cleaning technology:	Vacuum cleaning
Area of application:	Standard rooms in homes.

Vacuum cleaning is one of the few fields of application for which a mass market has already opened for service robots in general and cleaning robots in particular. The most successful system in this segment is iRobot's Roomba robot (Fig. 70.1), which consists of a cleaning robot and a base station. The circular cleaning robot stands atop three wheels, of which two are drive wheels and one a caster wheel, and navigates an unfamiliar environment completely autonomously. Essentially, the robot operates automatically [70.17].

In principle, it cleans on the basis of a classical vacuum cleaner with a powerful vacuuming unit and rotating *brushes* configured so that even dirt in the robot's boundary area is picked up. A dirt detecting sensor is located in the suction zone.

The path being cleaned does not have to be programmed. Equipped with optical *ranging sensors* and *contact sensors*, the system detects when it nears an obstacle, proceeds toward it at reduced speed, and changes its path direction upon contact. Ranging sensors directed downward detect stairs and drop-offs and generate a change of path direction as well.

Path direction is not changed randomly. The robot utilizes sensor data to analyze its environment and selects one of four motion patterns depending on the situation: spiraling, wall following, room crossing, and dirt detection.

Dirt detection is selected whenever larger quantities of dirt are detected in the suction flow. The robot reacts by increasing suction power and follows a spiral motion pattern until the quantity of dirt drops again.

Virtual walls can be used to limit the robot's workspace. These are generated by stations which emit an *infrared beam*. If its battery charge drops below a critical value or it has finished cleaning, the system returns on its own to its *base station*, which emits an infrared beam that acts as a guide beam for the robot.

Systems from other manufacturers include:

- The Kärcher RC3000 (Germany) is an autonomous vacuuming robot for household use (largely similar in design to the Siemens VSR8000). It is the only household appliance that disposes of collected dirt in its docking station [70.18].
- The Infinuvo Cleanmate QQ2 is an autonomous vacuuming robot for household use. It additionally kills germs with an ultraviolet (UV) lamp and freshens air with fragrance capsules [70.19].
- The iRobot Scooba (USA) is Roomba's successor that not only vacuums but also wet mops [70.17].
- The Electrolux Trilobite (Sweden) was introduced as the first vacuuming robot for household use in 2001 [70.2].

Other systems that at least deserve brief mention are the LG RoboKing, Hanool Ottoro, Black&Decker ZoomBot, and Sharper Image eVac.

70.2.2 Roofs and Facades

A number of facade cleaning robots have moved well beyond the research and prototype stage and are being operated as special developments exclusively on specific facades. Since relatively little time and effort is required to adapt remote-controlled systems, they will quite likely be used on other facades in the near future.

Filius Glass Roof Cleaning Robot

Developer:	Fraunhofer IFF, Germany
Type:	Professional roof cleaning system
Operating mode:	Remote controlled
Cleaning technology:	Wet roof cleaning
Area of application:	Berlin Central Train Station, Germany.

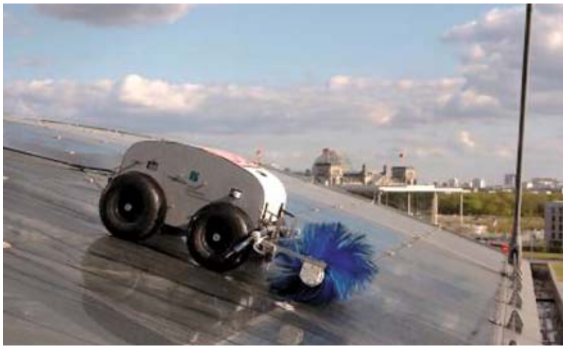

Fig. 70.3 Fraunhofer IFF Filius roof cleaning robot

The Fraunhofer IFF specially developed a remote-controlled cleaning robot for *Berlin central train station* in Germany (Fig. 70.3). However, it can also be used on other roofs with comparable geometries once the appropriate infrastructure has been installed.

Filius is a *remote-controlled*, *semiautomatic robot* that can navigate obstacles with heights of up to 200 mm. Onboard cable winches secure Filius to a *gantry* on the roof ridge from which it is supplied with power and water through a cable and a hose. As cleaning progresses, the gantry moves incrementally so it is always located above the robot.

Dirt is loosened by a rotating brush mounted on the front, and is then rinsed away by a nozzle bank behind the brush. An operator assumes the control of action functions such as path direction and brush activity by remote control.

Wobble sticks and ultrasonic sensors detect travel across the roof surface and an emergency stop prevents operators from driving the robot over the roof's edge.

Its all-wheel drive makes the robot extremely maneuverable on all terrain. Ramps laid out enable it to navigate the gantry's rails and expansion joints between individual roof areas for instance. Thus, the robot can be positioned and used on the entire surface of the station's roof.

Feeder lines on the roof, fed with high-pressure *softened water* by a supply vehicle, supply water to the gantry.

RobuGlass Glass Roof Cleaning Robot

Manufacturer:	Robosoft, France
Type:	Professional roof cleaning system
Operating mode:	Remote controlled
Cleaning technology:	Wet roof cleaning
Area of application:	Louvre Pyramid (France).

A remote-controlled robot cleans the glass Louvre Pyramid in Paris, France. Combining suction and caterpillar tracks, the robot travels up and down the triangular surfaces. The absence of any overhead securing device is a special feature of the Louvre robot. Technically, it is designed so that the frictional force of the walking mechanism suffices to prevent it from sliding down the sloping surface in the event of a malfunction. Operators at the foot of the pyramid supply it from below through cable and hose, the compressed air needed being provided by equipment located on a supply vehicle. Rotating brushes do the cleaning and a car windshield wiper dries the path of travel during downward travel [70.20].

Compared with other facade cleaning robots, the Louvre system has a very simple design. The minimum of distinctive features of the facade substantially reduces complexity. First, the triangular surfaces are completely level, only interrupted by silicone joints. Consequently, a very simple walking mechanism can be used since there are no obstacles to be navigated. Second, the system cannot fall when it travels across the sloping surfaces, thus making an overhead securing device unnecessary. Safety engineering accounts for a large part of other facade cleaning robots' systems and weight. Third, the sloping smooth surfaces allow water from cleaning to simply run off. This simplifies the cleaning system. Fourth, the space around the pyramid is navigable by a vehicle and the system can be recovered with a small crane at any time. Its relatively short cleaning paths enable supplying the robot from below. The requisite cables and hoses are simply pulled along the glass.

Glass Roof Cleaning Robot for Leipzig's New Exhibition Center

Developer:	Fraunhofer IFF, Germany
Type:	Professional roof cleaning system
Operating mode:	Autonomous
Cleaning technology:	Wet roof cleaning
Area of application:	Entrance hall of Leipzig's new exhibition center (Germany).

Two *fully automatic cleaning robots* have been cleaning the 25 000 m^2 glass hall of *Leipzig's new exhibition center* in Germany since 1997 (Fig. 70.4). The roof consists of a glass facade suspended from a steel structure. Accessing it with a gantry alone or other access equipment would be extremely complicated.

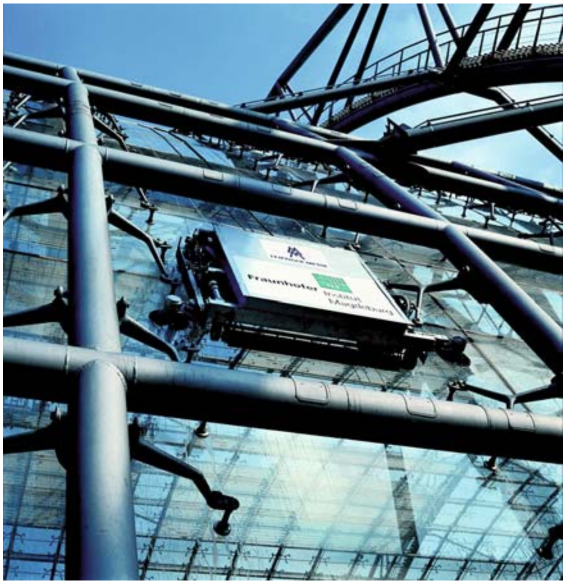

Fig. 70.4 Fraunhofer IFF cleaning robot in Leipzig

A *gantry* transports the robots along the roof ridge and uses small hoists to lower them onto the glass surface between the pane mounts. The robots then move downward under the steel trusses and between the mounts, cleaning the glass. Upon returning to the top, the robots are picked up by the hoists and shifted to the next path. A broad roller brush cleans the entire surface of the facade lane by lane, starting at the eastern end of the roof and ending at the western end. Since the robots are unable to move around the mounts, these areas are cleaned by disc brushes on retractable arms. *Chemical-free deionized water* is sprayed onto the glass to moisten and wash away dirt mobilized by the brushes.

The gantry on the roof ridge secures each cleaning robot with two Dyneema ropes and supplies each with power and water through its own cable and hose. To prevent damaging the panes of glass and silicone seals, hose, cable, and securing ropes are coiled and uncoiled inside a robot and thus laid down on the glass instead of being dragged over it. Furthermore, since the bearing wheels are not driven, the two securing ropes are used to correct the robot's direction of travel. A fifth wheel only provides the necessary drive in flat areas.

The steel structure limits the size a robot may have. At an overhead clearance of 38 cm, the robot's height is just 30 cm. The travel path is 45 m long and runs from the ridge between the pane mounts down into the eaves. The distance between mounts limits the robot's width to 1.5 m.

Odometer measurements of the distance covered by two wheels are supplemented by *eddy-current sensor* measurements of the distance covered using the mounts as reference marks. In addition, the distance to the mounts to the robot's left and right is used to correct path direction, controlled by adjusting the coiling of the two ropes. Expansion of the hall due to heat as well as the general tolerances of the mounts' uniformity make navigation between mounts more challenging.

The gantry and robots move fully automatically and are monitored from a master control room where exact positions and actions are displayed. The robots also accept abstract commands from a manual control menu [70.21, 22].

CleanAnt Glass Facade Cleaning Robot

Manufacturer:	Niederberger, Switzerland
Type:	Professional facade cleaning system
Operating mode:	Autonomous
Cleaning technology:	Wet facade cleaning.

Consisting of two limbs with suction cups attached to both ends, CleanAnt constitutes a *walking kinematics* with five degrees of freedom (Fig. 70.5). While one foot is fixed on a pane, the second swings into the next walking position or moves over the surface to clean a pane. A control computer synchronously controls and positions the axles, *inverse kinematics* identical to industrial robot controls determining the positions of the joints. However, its base coordinate system changes when the fixed foot changes.

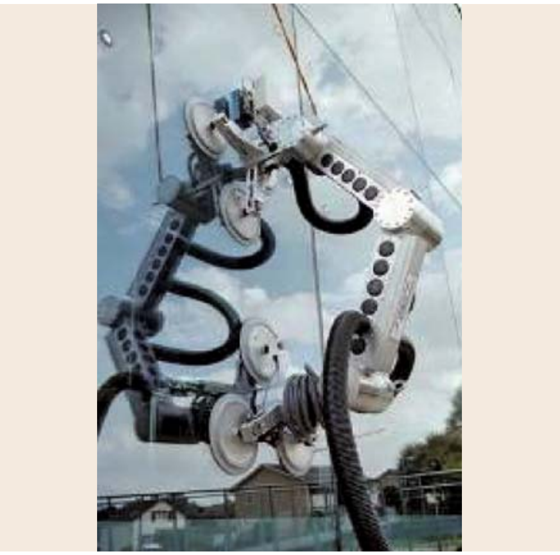

Fig. 70.5 CleanAnt climbing robot

The system automatically holds itself on the facade being cleaned, thus making it possible to clean vertical, overhanging or even curved facades. A slack rope secures the cleaning system and only goes taut should the system fall, thus preventing it from falling entirely.

Transceiver units on the building's corners, which triangulate current position, monitor its position on a surface. The surface being cleaned is modeled in computer-aided design (CAD) and uploaded to the robot control system. The robot then follows a predefined motion path autonomously.

While the complicated walking pattern, the few degrees of freedom, and the limited size of the cleaning unit prevent the system from covering large areas, it still qualifies as a service robot since it is able to clean surfaces that would otherwise be inaccessible, i. e., it can easily clean vaulted surfaces. Moreover, CleanAnt can move around corners or from wall to ceiling and navigate larger recesses or obstacles.

Wet brush cleaning and semidry cleaning with fleece or dry ice can be applied as cleaning technologies. A hose supplies the requisite media from above or below. For special operations, CleanAnt can also be deposited onto a facade manually, e.g., from a gondola, and maneuvered into specific areas by remote control.

While it is marketed for professional facade cleaning, CleanAnt is the only robot cited here that is not yet in operation. Nonetheless, it deserves mention if only because its design represents such a great departure from conventional robots [70.1, 23].

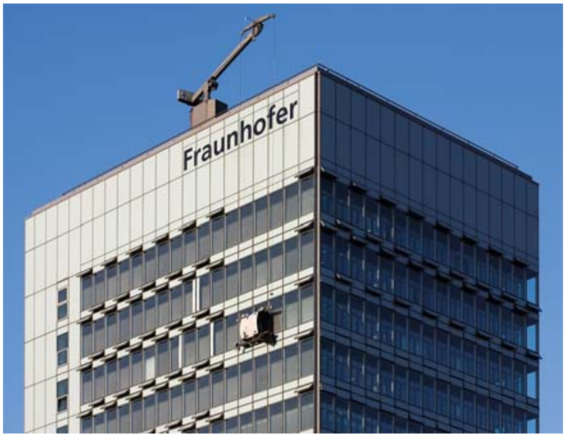

Fig. 70.6 SIRIUSc facade cleaning robot for automatic cleaning of high-rise buildings

Other facade cleaning robots include:

- The Fraunhofer IFF's SIRIUSc cleaning the *vertical facades* of the Fraunhofer-Gesellschaft's headquarters in Munich, Germany (Fig. 70.6) [70.22, 24, 25] and
- Beihang University's SkyCleaner III in operation on the Shanghai Science and Technology Museum in China [70.26].

70.2.3 Ducts and Sewer Lines

Regular cleaning of sewer lines is a basic measure to ensure they operate reliably. Cleaning of ventilation ducts on the other hand is not essential to operational reliability but arguably to protect people's health. Although sewer lines and ventilation ducts have similar geometric properties, the boundary conditions for cleaning robot operations differ fundamentally. Two systems serve as examples of ventilation duct and sewer line cleaning respectively.

Multipurpose Duct Cleaning Robot

Manufacturer:	Danduct Clean, Danmark
Type:	Professional duct cleaning system
Operating mode:	Remote controlled
Cleaning technology:	Brushes, dry-ice cleaning

The Danish company Danduct Clean's multipurpose robot is a universal system that cleans and inspects ventilation ducts. An all-wheel drive robot platform serves as the carrier system. The overall system does not have any collision sensors. However, two cameras directed toward the front and the rear relay a direct impression of the robot's environment. The carrier system is outfitted with different cleaning systems depending on the case of application.

Rotating brushes are used in dry ventilation ducts to remove dust clinging to the walls. Various brush systems are available depending on the duct geometry. A *dry-ice cleaning system* is employed in exhaust areas of kitchens and the like where sizeable grease deposits form in ventilation ducts. Temperatures as low as −79 °C facilitate their removal.

Irrespective of the cleaning system used, cables with lengths of up to 30 m supply media and transmit data to an external control box. The robot is controlled from the control box by joystick based on camera feedback. *Cruise control* is additionally available for long, straight duct sections.

To effectively remove loosened dirt, inflatable balloons seal off the duct section being cleaned. A powerful suction unit is hooked up to the duct opening in the direction of work and extracts loosened dirt from the duct [70.27].

Other duct cleaning robots are manufactured by:

- Indoor Environmental Solutions, Inc. (USA) [70.28]
- DRY ICE Engineering GmbH (Germany) [70.29]
- HANLIM MECHATRONICS (South Korea) [70.30].

Sewer Cleaning Robot

Developer:	Fraunhofer IFF, Germany
Type:	Professional sewer cleaning system
Operating mode:	Automatic
Cleaning technology:	High pressure.

Isolated sewer cleaning robots exist for inaccessible sewer lines. Some remote-controlled inspection robots for small sewer line diameters can be outfitted with high-pressure nozzles. As a rule, however, small sewer lines are cleaned with cleaning nozzles that utilize high-pressure water for propulsion.

Contracted by the Emschergenossenschaft in Germany, the Fraunhofer IFF developed a fully automatic cleaning robot for sewer lines with diameters of 1600–2800 mm. The system employs an ejector nozzle to mobilize deposits that are underwater and high-pressure water to clean the pipe wall above the waterline in sewer lines that are 20–40% full at all times. The system can clean sewers up to 750 m in length. The wheel-driven cleaning system is roughly 4 m long and weighs 2.5 t. An *ultrasonic scanner* monitors the cleaning results underwater and a camera monitors the area above water. A specially equipped vehicle on the street level supplies the cleaning system with up to 250 l of water per minute over a distance of up to 750 m with a nozzle pressure of over 100 bar. The cleaning system dependably navigates in the sewer line and system recovery is ensured through the cable connection [70.22, 31].

70.2.4 Swimming Pools

Swimming pools accumulate large quantities of dirt on a daily basis. The relatively large surfaces gather dirt out of the air and off swimmers. Public swimming pools are subject to hygiene codes with strict water quality limit values that necessitate regularly cleaning the bottom and walls of a pool. Underwa-

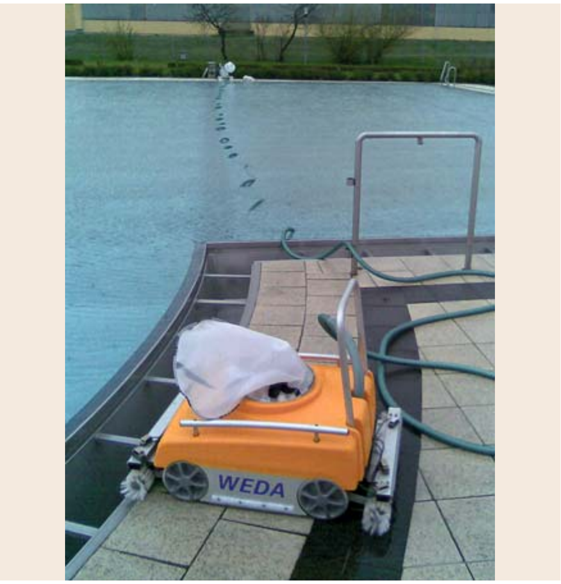

Fig. 70.7 WEDA B680 pool cleaning robot

ter cleaning machines have been in use since the 1970s. Such pool cleaners qualify as service robots since they move and systematically navigate pools autonomously. While the various manufacturers' systems share virtually the same robot engineering concept, their designs, target markets, and cleaning systems differ.

B680 Pool Cleaning Robot

Manufacturer:	Weda, Sweden
Type:	Professional pool cleaningdiffer system
Operating mode:	Autonomous, remote controlled
Cleaning technology:	Brushes, water filter system.

The base of Weda's B680 *pool cleaning robot* is a *tracked vehicle* maneuverable by separately controlling its left and right track (Fig. 70.7). Its forward speed is approximately 0.25 m/s. A *water pump* suctions in approximately 1200 l of water per minute on the underside and rinses it through a reusable *particle filter*. Common systems for residential use only manage approximately 250 l/min. The suction generated beneath the system is sufficient to enable the pool cleaner to traverse vertical walls underwater. Rotating brushes loosen dirt particles in front of and behind the unit, moving them in the direction of the suction opening. Power is supplied by a cable connected to a base station on the edge of the pool. It is uncoiled and floats on the surface during cleaning.

The robot is internally balanced in such a way that it glides gently downward and lands on its *feet* when lowered into a pool or when it detaches from a side wall.

Electronics in the B680 were kept to a minimum so that the unit is as easy for users to understand as possible. Contact sensors to the front and rear of the robot are used for *navigation* and reverse the drive direction when pressed. The unit has a slightly oblique front bumper that generates the slight change in direction when it contacts a pool wall. As a result, it reaches the opposite end of its path on its return travel somewhat offset. This simple navigation technique enables the complete cleaning of rectangular pool surfaces quicker than through random motion.

A pool cleaner is placed in the water during a pool's off hours and activates itself with a time switch after a short wait, by which time the water has calmed and dirt particles have settled. The cleaning is finished in a few hours and the unit deactivates itself for retrieval from the water the next morning. Control keys execute the requisite maneuver. The filter bag size is dependent upon its planned hours of operation. If it is too small, it clogs quickly, thus diminishing cleaning performance. In such a case, the cleaning robot would merely be embarking on a joyride and would lose traction as suction decreases [70.32].

Other manufacturers of professional and household pool cleaning systems include:

- Maytronics' (Israel) pool robots are intended for residential use and smaller pools. Maytronics offers the only battery-powered robot. Maytronics products are marketed globally under various names [70.33].
- iRobot (USA) offers several models that suction up and filter dirt in water [70.17].
- Aquatools (USA) offers robots for residential use and smaller public pools.
- Mariner 3S (Switzerland) sells professional pool cleaners. Instead of collecting bags, some units use filter cartridges that are cleaned afterward with auxiliary equipment [70.34].

70.3 Emerging Trends

Especially in the domain of cleaning, service robots already provide many different options for relieving people of dangerous, stressful, and/or monotonous work and are penetrating both household and professional market sectors. Household systems have technically simple and low-cost designs and are already being sold in large numbers. Professional systems are technically complex, flexible, cost effective, efficient, and easy to operate. However, since they fail to fulfill the requisite criteria in many cases, they have not yet established themselves as mass products. Nevertheless, numerous individual solutions exist for special applications such as facade or pool cleaning.

To the extent that they do not fully navigate surfaces when geometries are more complex or environments are dynamic and generally can neither navigate themselves nor coordinate tools better than humans, professional cleaning robots' sensory and cognitive capabilities continue to limit their universal and cost-effective use.

Such cleaning robots will not become mass products until their cost effectiveness, performance, efficiency, and total attendant costs make them superior to manual cleaning. Further development of service robots' cognitive capabilities, environment modeling sensor systems, and multimodal user interfaces is being pursued worldwide for other fields of application and is a fundamental prerequisite to establishing cleaning robots in the professional sector.

71. Automating Information and Technology Services

Parasuram Balasubramanian

While the information services industry dates back to the 15th century AD, the information technology services is as young as 60 years. Yet the pace at which both have grown is phenomenal, and this is tied to the evolution of computer technology. Networking of computers and people through the Internet has moved into high gear. It has also given birth to multiple business segments in the process. Delivery of data and information, data processing, business process outsourcing, analytics, and printing and display solutions are the five segments identified within the information services. Computer-aided software engineering, independent software testing and quality assurance, package and bespoke software implementation and maintenance, network and security management, and hosting and infrastructure management are covered as segments within information technology services. The automation path of each segment is reviewed in detail. An impact analysis to identify the changing landscape is described. Finally current trends are traced, followed by predictions for future developments.

71.1 Preamble

The design specification for the electronic voting machines (EVMs) used in 2004 national elections in India had to take account of the high level of illiteracy among citizens, cater for more than 14 different languages, tackle poor infrastructure in terms of road network and power availability in rural polling stations, and accept manual methods of voter authentication [71.1]. Nearly 1.3 million EVMs adhering to the above specification were deployed in the election, in which 330 million citizens voted. The election process went off without any significant problem with respect to the EVMs. Meanwhile in Europe, near Paris, a high-technology company has been engaged in using crash simulation software on Intel personal computers (PCs) to model and test new-generation vehicles to meet regulatory requirements without building expensive prototypes [71.2]. Not to be left behind in the innovation race, many firms in Europe and the USA have been busy delivering portable car navigation systems using the global positioning system (GPS) to the mass market.

These three cases represent the current state of the art in automation in information and technology services industries. The contexts are different and the level of automation varies, yet all three are powerful examples of information technology making its impact on mankind. The transformational power of this industry, as it impacted on the USA from the colonial period to current times, is traced by *Chandler* and *Cortada* [71.3].

The progress achieved is significant and exponential over the past 60 years, ever since computers entered this arena. As a general-purpose machine, the computer has invaded almost all aspects of human life. Computerization has resulted in productivity gains that could not have been dreamt of until the 20th century. It has been a process of unceasing innovations, integration of diverse devices, seamless merger of hardware and software, and evolution of new market paradigms. It has also given birth to an industry focused on providing information technology (IT) services to companies, governments, universities, and the public at large. It is worth studying this process to understand the growth of this industry and where it is headed.

71.1.1 Evolution of the Information and Technology Services Industry

Johann Gutenberg introduced the printing press in 1436 AD in Europe and is credited for opening the doors to the Renaissance and the scientific revolution [71.4]. The information services industry was born with the mass production of books (within the next 50 years 8 million books were printed) and it facilitated sharing of knowledge among scholars, particularly in Europe [71.5, 6]. The mass media industry consisting of newspapers, magazines, radio, television, and advertising, however, had to wait until the 19th century (for Marconi, Edison, and Walter Thompson to give birth to). A brief view of its growth in the USA is contained in [71.7]. The invention of the telegraph and Morse code by Morse in 1835 and the telephone in 1870 by Graham Bell, and their rapid spread of usage, along with the above, ensured that the spoken word joined the printed one to be shared across the world. Emile Berliner, standing on the shoulders of Edison and other eminent scientists, patented the gramophone, thus paving way for the music industry. A comprehensive view of each of these inventions and inventors is available on the Internet [71.8].

However, a parallel development over the centuries, in mathematics coupled with mechanical and electronic devices, led the development of information technology. Calculators (Pascal, 1642) gave way to the analytic engine of Babbage (1832), and Hollerith's tabulating machine was used first in the 1890 US census. The middle of the 20th century saw the invention of computers and the world has been spinning fast ever since. Along with computers, the information technology services industry was born in the 1950s and has grown in multiple dimensions [71.9].

Computer architecture separated the data input from its processing and output layers and exploited the distinction between data and logic. Advances in input devices, storage devices, processors, and data presentation layer during the past 60 years have come about by the marriage of information services technology components with computer devices. The distinction between telephone, television, and computer is blurring and feeding the growth of services at a furious pace.

71.1.2 The Opportunity for Automation

The first generation of computers could perform various mathematical and logical operations while the data had to be stored in an external media. The machine had very little capacity to hold data. The growth in computerization over the next six decades can be studied in multiple dimensions. The technological developments in the processor, input devices, and output devices define the first dimension, while advances in software technology constitute the second. Along the way there was integration among these devices as well as embedding of software into hardware, which played a catalyst's role in further automation.

Computers were networked during the 1970s, which paved way for the next wave of automation of tasks carried out in multiple locations by diverse groups. They acquired online and real-time capabilities, thus forsaking their batch processing culture. It did not take long for human ingenuity to invent the multiprocessing, multitasking systems, network security, and virtual authentication solutions. The powerful combination of hardware and software with these features resulted in many more activities becoming automated.

If computers are capable of storing vast amounts of data and perform complex processes in seconds, can they then be asked to perform the role of experts (expert systems), acquire human-like intelligence (called artificial intelligence) or at the least detect patterns and extract knowledge out of available data (knowledge-based systems)? Commonly grouped under the title of machine learning, these topics have become the enduring quest of many researchers over the past three decades.

Work flow is integral to all processes performed manually or otherwise. Work flow automation became a logical target for development in the early 1980s, coupled with the development of groupware that facilitated concurrent working of multiple teams. Computers had stepped out of the data processing and data storage zone by this time. They were capable facilitators for information sharing and multigroup multiprocess working.

Introduction of personal computer, starting from the late 1970s, into the global market brought a fresh paradigm to computing and automation. The gates were opened for mass application and coverage of every human endeavor by PCs. Enormous creativity was unleashed by technophiles all over the world. It was no longer confined to data processing; text and word processing became common. Slide rules and calculators gave way to spreadsheets. Transparencies were no longer the preferred means of making presentations as they were replaced by PowerPoint slides.

Impressive as they are, these developments pale in significance when the impact of the Internet is considered. Since the invention of the World Wide Web and the browser technology by Tim Berners Lee and Marc Andreessen, the universe of computers has been flipped over once again. In less than a decade of its introduction, the Internet phenomenon has lead Thomas Friedman to declare that it is a flat world.

The power of the Internet has been fully leveraged by electronic mail from the mid 1990s. Hotmail, founded by Sabhir Bhatia, became an instant hit as it promised and provided connectivity from anywhere to anyone. The data and text sharing power of computers and the Internet has been enhanced to recognize voice, feel (through touch screens), still and video images, and to recognize patterns. Convergence of devices has accelerated the use of the computer as a phone and a television too. Apple made a significant business breakthrough with its iPod to share music through the Internet.

Meanwhile the business community has enabled internet-based transactions, including financial. Universities have enriched their student interaction and grown the online and distance education segments. And the government sector has discovered the potential of this technology by facilitating digital submission of tax returns and other filings. In short, this revolution has touched every segment of human activity and innovation, and automation at unprecedented levels continues to fuel its breadth and depth.

These developments have impacted on every business segment of the information and technology services, which is the focus of our study. We will identify the key segments and study each in depth in the following Sections.

71.2 Distinct Business Segments

The information and technology services industry is not a homogenous industry but rather consists of many segments, each with distinct characteristics. At a macro level, information services (Sect. 71.3) need to be separated from information technology services (Sect. 71.4).

Five significant segments can be recognized within the information services (Sect. 71.3), consisting of delivery of data and information (Sect. 71.3.1), data processing (Sect. 71.3.2), business process outsourcing (Sect. 71.3.3), analytics (Sect. 71.3.4), and printing and display solutions (Sect. 71.3.5).

Media such as newspapers, journals and magazines, radio and television, and the Internet serve as channels of information delivery. The content delivered can vary from political and social news events to weather and sports or stock and commodity prices. Reuters and Bloomberg are examples of a specific type of content providers. Automation-induced changes in this industry can be tracked by studying these two firms over the past decades (Sect. 71.3.1).

Data processing as a service commenced in the mainframe era when computers were expensive and required special skills to program and operate. It was typical to do business functions such as financial accounting or payroll processing or reconciliation of interbank transactions or process examination results in large universities using third-party data processing services (Sect. 71.3.2). Technological advances in computers and allied peripherals have impacted heavily on this segment; hence it is worthy of separate classification.

Companies the world over have found the business environment becoming complex due to geographical spread, globalization, product variety, and legislation to be complied with. Many times these challenges have resulted in attention and key resources being diverted away from core business to auxiliary purposes. Hence, companies have longed for service providers with appropriate expertise and scale to whom they could outsource auxiliary business processes such as employee benefits management and insurance claims processing. Networking of computers, proliferation of desktops, and the ubiquity of the Internet during the past two decades have enabled the emergence of third parties who can provide these business process outsourcing (BPO) services (Sect. 71.3.3). While outsourcing data processing results in only the data being handed over, business processing leads to data, (occasionally) people, and processes being handed over too. The service provider then has great opportunity to innovate and simplify the processes on an ongoing basis.

Data and business processing services are strictly transaction processing solutions that handle enormous volume of data. They are however governed by the policies and decisions taken by the firm; for example, an airline with a goal to maximize revenue would decide on creating multiple classes of service in a given flight, price them differentially, and divide the total seats available into these classes based on a rationale. This is called revenue management. Apart from selling seats on an ongoing basis, the airline has to assess and evaluate the effectiveness of these decisions periodically. Analytical processing is a line of service facilitating such reviews and revisions (Sect. 71.3.4). The skill sets required and the tools utilized in analytical processing are very different from those relating to data or business processing.

Advances in technology have changed the way in which information is delivered as an output (Sect. 71.3.5). Convergence of telephone, television, and computer technologies has created innovative solutions that were hard to imagine a few decades ago. Automation of mechanical, electrical, and electronic devices when coupled with computers has opened up a new domain for control systems; these developments are to be studied in this segment.

The information technology services (Sect. 71.4) can be segmented into computer-aided software engineering (Sect. 71.4.1), independent software testing and quality assurance (Sect. 71.4.2), package and bespoke software implementation and maintenance (Sect. 71.4.3), network and security management (Sect. 71.4.4), and hosting and infrastructure management (Sect. 71.4.5). While these are by no means exhaustive, they represent the key segments at present.

Software development has progressed rapidly from machine-level coding to programming in high-level languages to an environment with almost no need to code. The developer community recognized the need and feasibility of automating many of the tasks they perform, early in the game. Computer-aided software engineering (CASE) tools emerged when their generic utility was discovered (Sect. 71.4.1). This segment is to be explored in detail.

As the size of software code has increased, so has the time and effort required to test it. Nearly 30% of the total effort for developing software is consumed by the testing activity alone. Testing is both manpower and domain knowledge intensive. It calls for comprehensive understanding of the business environment within which the software has to function, the assembly of platforms and tools used, and the methodology used for product development. While many software bugs can be innocuous, some can have a disastrous impact on system deliverables. Automation has changed the way in which testing and quality assurance tasks are performed in many organizations. Third-party vendors have emerged to provide this service independent of the developers (Sect. 71.4.2).

The landscape of systems has undergone a metamorphosis from its early days to current periods. Every system was a custom-developed system (known as bespoke) to start with. However the opportunity to reuse design and code was spotted soon. The other end of this spectrum consists of packaged software which has the highest level of efficiency in terms of code reuse, besides the obvious benefit of quick implementation. In large corporations it is common for both to coexist; for example, a bank may have core banking functions implemented through packaged software but its financial accounting and reporting may still be in a custom-developed system running for decades. The year-2000 (Y2K) scenario is the well-understood instance here. Once a system is developed, implementing and maintaining it is time, cost, and manpower consuming. The role played by automation in this segment (Sect. 71.4.3) is a fascinating study.

Proliferation of computers and associated software has given rise to newer management issues and challenges. When thousands of desktops are strung together with dozens of mini and mainframe computers and data moves across many departments and geographical locations, failure in any part of the network is bound to adversely affect the network as a whole. Besides, networks have to be managed for efficiency of resource usage as well. An allied concern is protection of data from unauthorized access. Network and security management (Sect. 71.4.4) has emerged as a major segment of information technology that has attracted firms with appropriate expertise and willingness to absorb associated risks. Product vendors have also emerged in this space, offering products to protect against viruses, intrusions with intent to steal data, etc.

Computers and information technology have become the backbone of many enterprises, commercial or otherwise. Yet they are not the core functions of traditional manufacturing firms or service providers such as banks, stock markets, and insurance companies. As computerization has matured over the decades, many firms have also aspired to hand over the entire set of activities and resources to expert service providers. Alternatively, vendors invest in such resources and provide hosted services at an appropriate charge. Hosting and infrastructure management services (Sect. 71.4.5) is thus a distinct segment in this domain.

The ten segments identified within the information and technology industry are studied in detail in the following sections. They are by no means exhaustive and they constitute the most significant segments at present, tet the scenario may be vastly different in a decade from now due to the rapid changes and developments taking place in this industry.

71.3 Automation Path in Each Business Segment

71.3.1 Delivery of Data and Information

Paul Reuters started a news and stock information service from London's financial district in 1851 using his telegraphic skills and 200 pigeons. His firm expanded its services rapidly to Asia and America within the following 20 years. By 1923, Reuters had started using radio transmission of data of stock prices, exchange rates, and news. It diversified into television (TV) media by the 1950s, and computer screen display of stock and commodity prices in the 1970s. It joined hands with Merrill Lynch in 2005 to float workstations for online financial information [71.10].

Michael Bloomberg founded his firm in 1982 to provide online financial data about companies and their performance with dedicated terminals to market analysts. By 1987 the firm diversified into launching a trading system and discontinued printing the user manual soon. The printed document was replaced by online features, online manual, and help screens. Bloomberg expanded into travel, news services, professional services, and email and got into magazines, radio stations, TV, multimedia, website, online trading, books, foreign exchange trading and so on in the ensuing decade [71.11].

Widespread use of the World Wide Web, during the past decade, has created a mass market for information services and has ensured that both the generation and distribution services are global and not dependent on the size of the firm. Every corporation, big or small, profit or nonprofit, business or social entity has launched its own website to share information. Thousands of firms have jumped into this business of designing and operating third-party sites. Very specialized or niche information, segmented by geography, age group, hobby or special interest, alumni groups, are all available today. Portals that serve as gateways have multiplied, along with content service providers. The industry has gained another orbit with the introduction of fast and efficient search engines from Yahoo and Google. Along with the growth of this industry, issues such as security of information, privacy protection of providers, and authentication of source have become critical. These needs in turn are serviced by another set of firms with software tools.

Expansion of services and diversification of channels are facilitated by advances in the computer industry and the media convergence phenomena. The cable service provider has become the Internet service provider as well. The Internet is being leveraged by firms such as Skype to facilitate teletalk and to view video-quality images. Convergence between television, telephone, and Internet devices is accelerating. Innovation management and product and market strategy issues are coming to the fore, along with this technological convergence [71.12]. Cellphones and other mobile devices can carry voice, text, image, and data, and link to the Internet. A fascinating future awaits us, with almost every household or office device becoming *intelligent*, to transmit, store or accept, and process data.

71.3.2 Data Processing

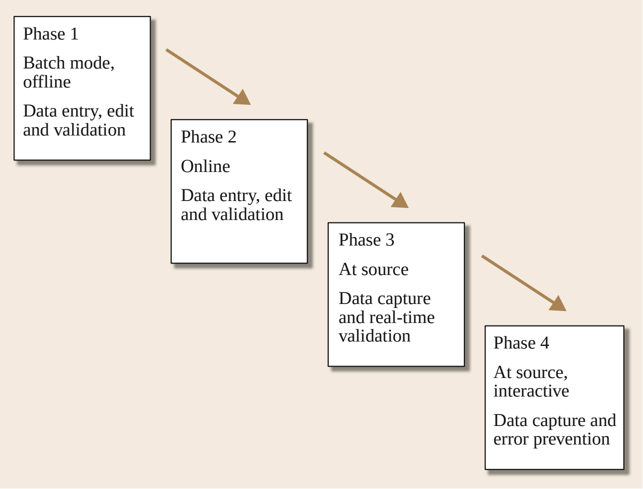
Data processing services consist of data preparation and data processing stages followed by data presentation to the user community. A comprehensive history of developments can be found in [71.13, 14]

Data preparation activities have gone through four major phases of evolution (Fig. 71.1).

Phase 1 corresponds to the early years when data was prepared in batch mode, offline, using data entry machines and punched cards. Edit and verification runs were performed on the computer to catch errors in punched cards. The prime objective was to detect and rectify deviations if any from the data contained in the original documents. After this clean up a data validation run was performed to identify logical errors in the data presented. Range checks and field comparisons were done before accepting a set of data for the processing run. The sequential nature of these activities and their time-consuming nature is apparent. During the next decade, technological advancement from punched cards to floppy drives (8″ to 5.25′ to 3.5′) contributed to data storage efficiency and cost effectiveness. Partial rectification and validation could be performed in the data entry system itself. New category of workers called data entry operators and input/output clerks were employed in the industry.

Once dumb terminals could be attached to computers and dispersed in a location, the online data capture phase (phase 2) began, in the 1980s. This lead to elimination of duplicated effort for data capture in many instances. Data edit and validation functions could also be performed online, thus saving effort, compressing time, and reducing errors.

Phase 3 can be related to the period of introduction of PCs and networking them with the processing systems. *At-source* data capture became feasible with real-time validation. Online help features started appearing and the next logical step was to prevent capture of erroneous data. Graphical user interface, pull-down menus, predefined fields, and automated cursor movements to control the sequence, all being software advancements, played a key role in significant enhancement to data capture efficiency and effectiveness. This was the period when job categories such as data entry operators and input/output clerks disappeared from the market place.



Phase 1
Batch mode, offline
Data entry, edit and validation
Phase 2
Online
Data entry, edit and validation
Phase 3
At source
Data capture and real-time validation
Phase 4
At source, interactive
Data capture and error prevention

Fig. 71.1 Data preparation phases

Phase 4, which is the current phase, is characterized by extensive networking using the Internet, intranets, and extranets. Data is captured not only through PCs but through other interface devices, such as telephones, card swiping machines, point-of-sale (POS) systems, and radiofrequency identification (RFID) readers etc., as well. Captured information is not just data but can be voice or image too. *At-source* data capture is now ubiquitous since the device can be in a customer location, remote, and man or machine; it is interactive for information sharing or data capture and facilitates decision choice for the user.

What does the future hold? Cross-validation of data from disparate systems (if he is buying an expensive car, has he been paying income taxes regularly?) is coming. Person authentication through biometric sensors or other means before accepting data is already present in some systems but is likely to become universal. Further smart systems are on the anvil for the future. The intent is to make every device, be it a refrigerator, microwave oven or army uniform, so smart that it transmits information proactively and in an automated manner.

The data processing stage has evolved from manual mounting of tape and disc drives, a human computer operator firing the sequence of operations through a console, inserting stationery into the printer, and managing it to total automation in five decades. The progress here has been continuous and can be credited to both hardware and software developments.

The operating system (OS) of the computer has learnt to be multitasking and to sense device changes automatically. It can act as per location or chronological requirements. It can time-stamp transactions. It can distribute work to multiple processors and assemble and present the output in a seamless manner. It can protect itself from intrusions and threats. It can also compile information regarding the system performance and create an alarm when needed.

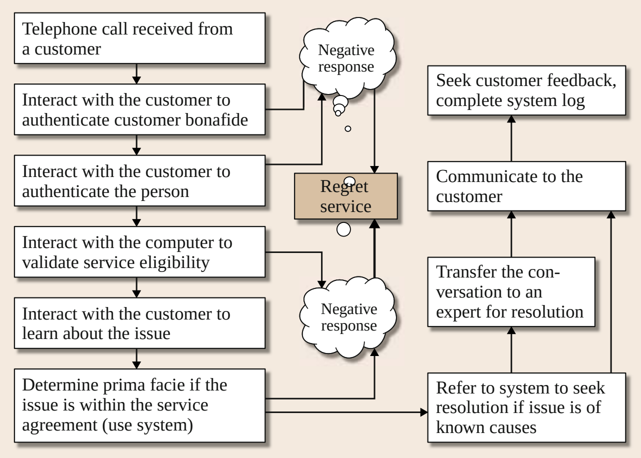
Data management has another aspect to it, namely the database architecture. Developments in database management have progressed from simple and serial records to hierarchical databases (evolved to optimize data management during the tape drive era) to network databases to relational databases (RDBM). *Codd* [71.15] enunciated the basic principles of RDBMs in the 1970s and thus facilitated the optimal way of data storage and retrieval for all media, hierarchical or random. Major advances in data processing have come from integration of RDBMs with OSs as well as storage media. Storage area networks (SAN) and network as storage (NAS) concepts have evolved in the past decade to access widely distributed storage devices and share their utilization effectively.

71.3.3 Business Process Outsourcing

Businesses run due to interaction with customers, vendors, and other stakeholders and based on the flow of transactions; for example, customers place orders with the firm (indent), and the firm, upon delivery of goods, seeks for the customer to pay (invoice). The payment is effected through a banking transaction [check, draft, electronic financial transfer (EFT)]. Note that goods and funds flow in the system but their flow is controlled through the flow of information. Before an order is executed, it is more than likely that a set of activities called order processing happens within the firm (sometimes interacting with the customer). There can be many tasks performed in order processing adhering to certain sequence and operating rules of the company. Most of the time these tasks are performed by human beings.

As discussed earlier, it is cost effective for many firms to outsource noncore business processes to a third party and to derive operational and cost efficiency. Travel bookings, employee payroll, and benefits processing are typically outsourced. Even financial accounting and tax preparation tasks get outsourced in typical small firms. Call centers and help desks are outsourced routinely these days. Outsourcing business processes to offshore service providers is a growing trend [71.16]. BPO can result in significant operational benefits as documented through many case studies in the *BPO Journal* [71.17]. Processes are typically interwoven with computer and manual activities. As an illustration, a help desk process is illustrated in Fig. 71.2.

It can be seen that the human processes are interwoven with machine processes. The human processes call for stand-alone tasks by the service provider as well as interactive tasks with the customer. Periodic reference to a database is needed. Often a decision has to be made, with or without the help of the machine.



Telephone call received from a customer
Interact with the customer to authenticate customer bonafide
Interact with the customer to authenticate the person
Interact with the computer to validate service eligibility
Interact with the customer to learn about the issue
Determine prima facie if the issue is within the service agreement (use system)
Negative response
Regret service
Negative response
Seek customer feedback, complete system log
Communicate to the customer
Transfer the conversation to an expert for resolution
Refer to system to seek resolution if issue is of known causes

Fig. 71.2 Help desk process

Processes where there is no interaction with the customer are called back office and the others are known as front office. The outsourcing opportunity arises due to many factors.

The volume of calls received by a particular firm or product division may be insufficient to invest in a system or to maintain a help desk internally without substantial idle time for the resources. A third-party service provider can be more efficient when its resources are shared across multiple companies. Substantial investment in domain expertise needed is yet another reason for outsourcing; for example, payroll processing for a firm operating in many states calls for current knowledge of state-level taxes and other labor rules and legislation and incorporating them in the system with no time delay.

It is common practice to hand over – lock, stock and barrel – the existing system (hardware and software), people, and processes to the outsourced vendor to gain business efficiency. Firms ensure the efficiency gains and continuing improvements through service-level agreements (SLAs). SLAs have become sophisticated in design but simple in implementation over the years. They specify the level of service satisfaction to be reached for different processes. Further strict control over accountability is established.

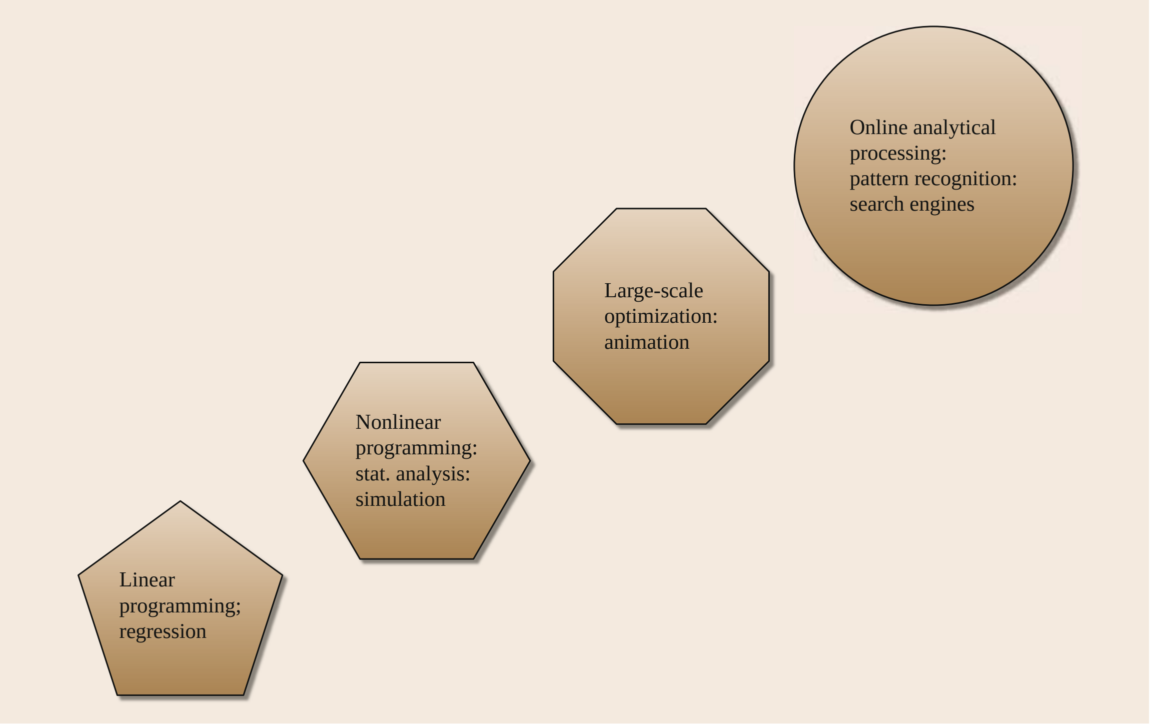
Vendors find numerous opportunities to automate and gain efficiency along the way. In the help desk example cited above, the first opportunity is to log all incoming calls automatically and sort them by probable cause; then to build the frequently encountered issues and their resolution database and add a voice-based system to guide the customer through resolution of simple issues. Expertise gained over the help desk system can be converted into frequently asked questions (FAQs) and incorporated into the online help features of the system, thus minimizing the need to call. The vendor firm can even share knowledge gained from one customer firm environment to others by using a common high-level issues-resolution team, if agreeable to all customers. Further periodic analysis of issue logs would reveal what issues are encountered most often and why. Then it becomes a valuable data source to modify or enhance the associated manual processes or the embedded software. It is not uncommon for firms to outsource business processes to standardize or streamline them across many segments when they are reorganizing or consolidating.

Many tools are available in the market to support BPO firms and their clients.

71.3.4 Analytics

Decision support systems (DSS) have played a prominent role in widespread adoption of computers from the early decades. As opposed to the challenges of storing and processing large volumes of data in transaction processing systems (TPSs), DSS have been computation intensive. See Chap. 87 for additional content on decision support systems. While operational researchers and other management science experts have been successful in mathematically modeling large business and engineering systems even in the 1950s, the implementation of these systems had to await advancements in hardware and software. Dantzig's simplex algorithm, invented in 1947, to solve linear programming problems and the invention of computer in the late 1940s can be taken as the starting points. It took another two decades before product mix optimization in refineries, route optimization and crew and vehicle scheduling in mass transportation systems, production scheduling, and many other large-scale problems could be solved in reasonable time periods (within an hour or much less) to be of practical value.

Inventory management, project management systems using program evaluation and review technique/critical path method (PERT/CPM) methodology, network flows optimization, and time series and regression analysis were the solutions implemented using powerful mainframe computers until the early 1970s. This period also saw the birth of discrete event and con-



Online analytical processing: pattern recognition: search engines
Large-scale optimization: animation
Nonlinear programming: stat. analysis: simulation
Linear programming; regression

Fig. 71.3 Growth in analytical applications

tinuous simulation techniques. They found widespread acceptance in the industrial world.

The ever-increasing processing power of computers coupled with their ability to store vast amounts of data served to fuel the growth of analytical applications. Very large-scale optimization problems involving hundreds of thousands of decision variables and constraints could be taken up initially with supercomputers such as those built by Cray. Similarly Silicon Graphics introduced the power of the computer into the world of animation, which meant that high-end engineering systems can now be simulated and visually represented on computer screens for better understanding and use.

Another remarkable shift has been the use of personal computers in analytics. Numerous tool vendors have exploited the exponential growth in computers' processing power to develop PC-based solutions, CPlex from Ilog, Frontline Solver, MSProject, SPSS, and SAS for statistical analysis to name a few. Similarly one can mention Arena and Automod in the simulation world.

One of the significant developments during the 1980s was the emergence of yield and revenue management concepts in the airline industry. Analyzing millions of transaction data from past flights, the team of operations research (O.R.) experts at American Airlines was able to come up with a fine-tuned strategy for pricing airline seats and dynamically altering them until flight departure. Success of these techniques encouraged the entertainment and hospitality industry, consisting of hotels, vacation travel, and recreational sports, to embrace these concepts and improve their profitability.

Corporate data usually resides in multiple databases in various formats. Recognizing the need to bring them under a common framework in a unified database, analytics vendors have floated data warehousing tools. Data mining solutions that can extract statistically valid inferences from these data warehouses have also emerged.

Analytical processing has gone online during the past decade. Online analytical processing (OLAP) tools from many vendors enable firms to perform analytics in real time and incorporate the decision variables into real-time control systems. Pattern recognition and search engines have been integral to many web-based applications. Google's success is to be credited to the optimized page-ranking algorithm tied to its search engine. Figure 71.3 traces the growth of analytics over the past decades.

Analytics is poised to play a significant role in corporate competitive advantage, as outlined by *Davenport* [71.18]. It can be a powerful tool in providing transparency, rooting out gray markets, reducing corruption, and being fair to all stakeholders where judgment is used to select some for negative treatment. This is covered by *Balasubramanian* [71.19].

71.3.5 Printing and Display Solutions

During their inception, computers relied on character display terminals and line printers. Computer output was either viewed on the terminal or printed. *Mayadas* et al. [71.20] have tracked the growth of this industry until the mid 1980s. During the batch processing days line printers were installed in computer centers. The operator had to insert continuous stationery, print multiple copies, and sort the output for dispatch and distribution. The principal issue to be tackled was the mismatch between the processing speed of the computer and the speed of the printer. Research efforts were focused on enhancing the printing speed step by step.

Dot matrix printers (DMPs) were introduced in the 1980s, with the significant innovation that a printed page could be either portrait or landscape style. It even became possible to print pictures, albeit at low levels of accuracy. DMPs were priced low and they captured the PC-based systems market aggressively. Inkjet and laserjet printers were introduced in the 1990s and have revolutionized the printing space. Systems are now free from the need for continuous stationery too. Color printing became common very quickly and the desktop printing (DTP) segment has evolved as a distinct area. With the emergence of DTP, preparation of high-quality slides for corporate presentation, university research reports containing mathematical symbols, and artwork on tee shirts all became possible.

Very soon printers became intelligent devices with the help of software. They could hold a line of printing jobs, schedule them based on priority, change fonts and features from one job to another, report paper or ink cartridge issues, take care of reverse printing, and eliminate human effort and errors. Postscript language and digital fonts were developed by Adobe Systems in 1982, thus facilitating drawings and image manipulation. Printers capable of engineering drawings and blueprints were not to be left behind. So are other innovations such as photo-printing machines, which are now ubiquitous. In the Internet age, network printers can act as copying or faxing machines as well.

The technology-lead changes in the computer screen market are equally impressive [71.20]. Graphical and iconic display is taken for granted now. However, it is a far cry from the character display terminals. Moving from cathode-ray tube (CRT) to light-emitting diode (LED) to plasma screens, computer system users have been empowered to display sophisticated images of simulated vehicle crashes, human organs, ocean floors at depth etc. along with traditional business graphs, tables, and legal documents. The field of data visualization is merging graphics and animation to enable dynamic, real-time perception and pattern recognition [71.21].

The need for an intermediary to analyze output, interpret results or initiate control action in process control systems has been minimized by the integration of computer-based systems. The console is a device for oversight, otherwise all controlling tasks can be done by the system. Automation from end to end is thus being enabled.

One of the visible trends for the future is continuing elimination of printed paper. Acceptance of digitally filed tax returns, electronic voting, and electronic mail as legally valid communication are good examples. Advances in digital certification technology play a catalytic role here [71.22].

71.4 Information Technology Services

71.4.1 Computer-Aided Software Engineering

There are four distinct stake holders in information systems, namely, system users (company executives), their subject of usage (such as factory operations), computer system operators, and system developers. Their expectations and requirements are not concurrent and are usually diverse. The responsibility to design the system to meet every stakeholder's needs, however, lies with the developers [71.23].

The key stages of software engineering are requirements analysis, functional specification preparation, architecture and system design, software development, testing, implementation, maintenance, and documentation. These are manpower intensive and were performed without the help of any tool to begin with. This scenario was to change soon.

Software engineering was the focus of the Defense Advanced Research Projects Agency (DARPA) and the National Institute of Standards and Technology (NIST) even in the formative years of computers [71.24]. However it soon became a mission critical issue for system developers such as IBM, EDS, Accenture, and HP. Confronted with the twin challenges of improving the quality of software and enhancing the productivity of software developers, many service providers turned to streamlining the processes, to adopting quality assurance methodologies, and to the tools of their trade, seeking solutions. They recognized that automating many life cycle activities of software development can bring immense benefits internally. This was, however, easier stated than accomplished.

The common business-oriented language (COBOL) and Fortran were the dominant languages for programming for business and scientific applications until the 1970s. By developing newer languages that were feature rich, that could handle multiple data types, and that were easier to learn and to deploy the industry sought to address its concerns. It was a daunting challenge to keep up with the evolution in database management [71.15] concepts too. A cherished dream of software developers to reuse code became a possibility, initially with subroutines and libraries and later with the invention of object-oriented methodology [71.25] and languages such as Smalltalk, Lisp, and C++.

Run-time efficiency is also a major concern with many systems. How does one ensure that only relevant sections of the code get executed without the need to carry along redundant code? This issue surfaces particularly when a developed system is striving to meet the functionality requirements of many customers with partially nonoverlapping requirements. Dynamic languages such as Perl, JavaScript, PHP, and Smalltalk provide this run-time flexibility. Hence, choosing the appropriate language becomes a judicious decision [71.26].

Efforts analysis of many major projects revealed that nearly 70% of resources are consumed by the pre- and post-coding stages of the software development life cycle. Besides, annual efforts expended to maintain the software were found to account for around 15% of the development stage. It dawned on the service providers that it is imperative to focus on both the pre- and post-coding stage activities also.

Design tools such as DesignAid, Excelerator, IEW, ADW, IEF, and Accenture's Foundation toolset (METHOD/1, DESIGN/1, etc.) became popular as they helped to streamline and standardize the design process, to serve as a means of communication with the end users, and to document the system. While many tools were on the PC platform, Unix and mainframe-based tools (AD/Cycle) were also available. They focused on structured systems analysis and design methods (SSADM) and managed to automate database schema, data flow diagrams, and entity relationship diagrams successfully. Developing program specifications and user documentation were partially automated. However, their attempt to automate code generation was of limited success. During this period, the requirement analysis and functional specification stages were not amenable to automation as they had to begin from ambiguous states.

SSADM [71.27] is a derivative of the traditional waterfall method of development. It called for performing each stage adhering to strict sequence. The premises were that inefficiency multiplies when one attempts to retrofit any function after the project has moved beyond design stages. The significant negative impact of this approach has been to extend the project duration to years and that the code becomes difficult to understand or to maintain later. Responding to the industry need for shortened implementation cycle and quick deployment in the field, rapid prototyping methodology in conjunction with the iterative mode of development have been evolved.

The advent of object-oriented methodologies (OOM) in the early 1990s called for binding logically defined data objects with their processing logic. Hence objects that are fully self-contained to deliver a specified function can be easily reused. This philosophy gave rise to object-oriented data modeling and object-oriented development. However, the significant change was to introduce the use case method of requirements capture. Tools such as RUT and Rational Rose helped to develop use cases efficiently. OOM has received significant help in implementation with the invention of the C++ language [71.28].

Yet another challenge was requirement traceability. An agreed functionality has to be captured in the beginning and it has to be ensured that it is carried forward all the way. It has not been easy to automate this task [71.29].

Often it is noted that the software development environment may consist of PCs, Unix machines etc. but the operational environment could include mainframes. Hence it became necessary to manage the configuration well during development so that issues confronted in transferring the software from one environment to another are minimized.

In addition, many, often 50 or more, programmers, testers, and designers were working simultaneously on different segments and stages of a large software project, and maintaining tight control over many versions became vital. Configuration management and version control aids such as WinRunner have come into play.

The emergence of web-based technologies during the past decade has given a great impetus to rapid prototyping and iterative method of development. The popularity of traditional CASE tools has reduced in this process.

71.4.2 Independent Software Testing and Quality Assurance

Testing has been an integral and essential activity in both the development and maintenance phases of any system. What needs to be tested, when, how, and by whom, are issues that continue to engage the attention of users and service providers.

The objectives of testing, however, have remained focused on fundamentals since the beginning. The essential role of testing before commissioning is to ensure that the system delivers the expected functionality with consistency and high reliability. However, there are many add-on objectives arising at various stages, which form part of testing and quality assurance.

Ensuring that the functional specifications of the desired system are drawn up accurately and comprehensively is a basic need for quality assurance. Only then can the system be designed to deliver what was intended. Requirements tracking across the life cycle stages however calls for both enabling processes and testing.

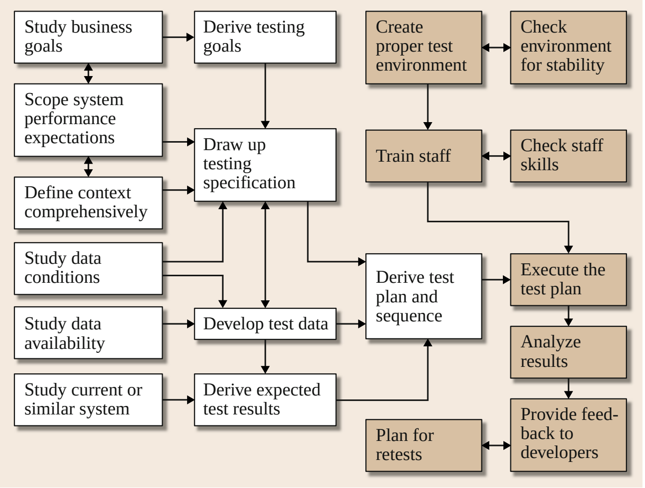
These two terms, namely testing and quality assurance, are not synonyms. Quality assurance goals overlap with testing goals during the testing phase to assure that the system performs as intended. It crosses the testing phase and exists in delivery, implementation, and maintenance phases as well. User experience in these subsequent phases needs to be captured and feedback loops created to ensure the expected level of quality of service.

It is necessary but not sufficient to draw the intended performance of the system only in terms of its functionality. Configuration, installation, interoperability, security, usability, performance parameters such as transaction processing and response time, privacy adequacy, etc. need to be comprehensively stated and tested as well. Furthermore, the likely variations in external environment within which the system needs to function have to be defined. Only then can the specification for testing be drawn up adequately. Both unit-level testing and integrated system-level testing are essential. Coupling interfaces to other systems must also be performed. Other than the above, regression testing, which means retesting the system comprehensively after a change has been incorporated, is often found to be mission critical. Practical circumstances have necessitated both black-box and white-box testing procedures to be adopted in a judicious mix. Planning the testing function, at a high level, is presented in Fig. 71.4.

Comprehensive testing for all possible data and environment conditions is time and resource consuming; in many cases it is impossible [71.30]. Given that many major systems need to be implemented in defined time periods (of between 6 months to 1 year) the daunting task is to determine what needs to be tested essentially and with priority. Hence the goal of testing has to be tied to the business goal itself. The testing phase and hence testing tasks have to stay within the time and budget constraints arising out the business goal. The testing specification has to take account of the functional and nonfunctional requirements, the environment, and expected data conditions.

Preparing test data is tricky. It has to be representative of all major scenarios. It also has to include occasional but mission-interrupting conditions. Extreme conditions are to be included as well. Preparing expected results is not easy or straightforward in many cases. This is due to the planned functionality of the system being new compared with what exists now, or sequential dependency among test results.

Note the steps involved in the test execution phase. Creating a proper test environment is coupled with checking to ensure its stability. Training staff who would perform the testing role also requires first ensuring that they have adequate skills. Once the test plan is executed and the results are analyzed, feedback is given for changes needed, and simultaneously planning for retesting has to commence.



Study business goals
Derive testing goals
Create proper test environment
Check environment for stability
Scope system performance expectations
Draw up testing specification
Train staff
Check staff skills
Define context comprehensively
Study data conditions
Derive test plan and sequence
Execute the test plan
Study data availability
Develop test data
Analyze results
Study current or similar system
Derive expected test results
Provide feed-back to developers
Plan for retests

Fig. 71.4 Planning the testing function

The opportunity to automate the testing tasks has tempted many researchers and service providers to aim high. Their quest to automate the entire function has met with no success. Instead, numerous support tools have been developed to set up and stabilize the test environment, execute test scripts, compile test results, and analyze them. Performance testing and load-testing functions have been automated to a high level.

Automated tests create a log of pre-existing conditions, test data, test plan to be executed, and test results. One of the major advantages gained here is repeatability of error conditions. They further facilitate shared learning from one test sequence to a similar test performed subsequently.

The market is full of products for facilitating automated testing. HP's WinRunner (to test user interfaces) and LoadRunner (to test performance), and IBM's Rational Suite of products (for testing across the life cycle and managing the test environment), are the tools commonly used in automating testing.

Quality assurance, with a broader mission of ensuring quality across all stages of software life cycle, has leaned on ISO 9001 and Six-Sigma approaches. The Software Engineering Institute (SEI) at Carnegie Mellon University chose to tackle this issue using a specific model for the software industry. It is called the capability maturity model (CMM). Level 1 of CMM represents ad hoc development while the highest level 5 stands for well-structured, disciplined, and self-learning processes. Templates are provided for self-assessment, then guidelines are given for moving up the CMM levels.

Rigorous quantitative techniques and metrics form part of this methodology. They measure quality parameters such as delivered defects, and time and cost overruns, and include customer satisfaction measures too.

The IT services industry has embraced these models and approaches to gain competitive advantage in the marketplace. Implementing these quality assurance measures has called for using numerous tools for automated capture of efforts, output, defects, etc. Most firms have developed tools predominantly in-house for these functions.

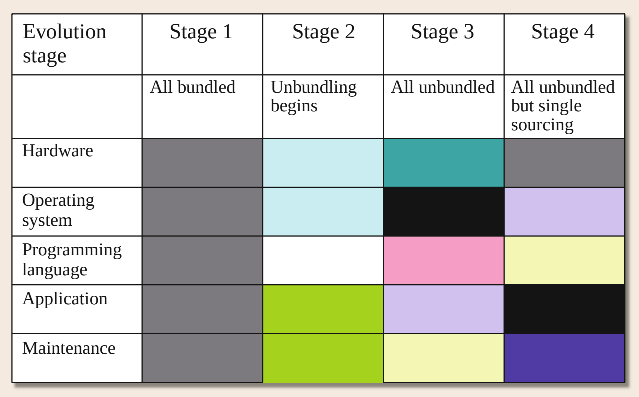
Offshore companies, who prefer to get nearly 75% of the development or maintenance work accomplished offshore, rely very heavily on these approaches for multiple reasons [71.31, 32]. Being higher up on the CMM level is a formidable marketing weapon. Combining this with the labor cost advantage, they are able to garner a larger share of outsourced assignments from firms in the USA and Europe. The client firms get both a cost and quality edge when they send work offshore. Secondly, the offshore firms usually employ a large number of young engineers with limited work experience. By enforcing strict adherence to processes they are able to deliver a consistent level of quality output to customers and not allow the inexperience of their workforce to impact on software quality. Finally, climbing the CMM ladder also means greater automation, which gives continuous improvement in developer productivity.

Long-term initiatives have a radically dramatic proposition, namely to eliminate the need for any testing and rework. Cost of quality (COQ) is measured as the total cost of testing and rework activities and resources. If quality is built into the software at every life cycle stage starting from requirements analysis then COQ can be minimized. Componentization and object-oriented development methodology, when combined, can lead firms towards achieving these challenging objectives in the future.

71.4.3 Package and Bespoke Software Implementation and Maintenance

During early stages (Fig. 71.5) all components of systems (hardware, operating system, programming language tools, applications and subsequent maintenance services) came bundled together from a single vendor (stage 1). However, it did not take long for the languages to break out of this pack. Fortran was followed by Algol and Pascal within the scientific community while COBOL remained strong in the business arena. Application development services along with continued maintenance were taken over in-house in many firms (stage 2). The unbundling phase expanded into every component of the system and, by the 1970s, total unbundling had come into play. Emergence of Unix as a dominant mid-range operating system was particularly endorsed by the scientific community. This played a critical role in unleashing the unbundling revolution during the 1980s (stage 3). However, the world woke up to an unprecedented level of segmentation when the PC and subsequent Internet era dawned. Components within the hardware are unbundled now and so are the development tools and application software.

With all this unbundling the business community was faced with a new crisis. When a system failed in operation, attributing responsibility became difficult and a contractual nightmare. Many firms also discovered that the range of expertise required to govern and manage a myriad of systems was vast and distracting from their mission. Hence a new wave has emerged since the 1990s, focused on integrated or bundled services. Many firms have chosen to go with a single vendor to provide the entire suite of services and manage the diversity of platforms and applications. Outsourcing the entire IT function on a multi-year basis is common for large firms. Coupled with this is the integration of applications into three large segments, namely, enterprise resource planning (ERP), supply chain management (SCM), and customer relationship management (CRM). The SCM pack is to link up with the suppliers and the CRM with the customers. ERP is the middle piece, where the firm converts supplies to goods and delivers to customers.



Evolution stage	Stage 1	Stage 2	Stage 3	Stage 4
	All bundled	Unbundling begins	All unbundled	All unbundled but single sourcing
Hardware	▨	▢	🟦	▨
Operating system	▨	▢	⬛	▤

Maintenance	▨	🟩	🟨	🟪

Fig. 71.5 Stages in solution implementation (*first column* cells indicate totally bundled solutions, *second column* indicates start of unbundling, *third column* indicates complete unbundling, *fourth column* indicates complete unbundling of the software, while customers tend to prefer a single source for their software and services)

Custom-developed applications always took more time than budgeted. They were delayed in development. The software was also found to be bug ridden. The IT services industry responded to this challenge by building packaged solutions such as JD Edwards for financial accounting, ManMan for factory operations management, PRISM for project management, etc. Over the years, transaction integrity concerns and processing efficiency requirements have led to the integrated suit of ERP applications such as SAP, MfgPro, and others.

A typical firm is likely to have a large set of custom-developed applications and packaged solutions running together. This has happened due to constant mergers and acquisitions.

Once implemented, these applications call for considerable dedicated resources to maintain and operate. The maintenance function covers detection and removal of bugs, dismantling existing manual or outdated technology interfaces, interfacing with newer systems, and changes to comply with changing regulations or enhancements to provide additional functionality. Furthermore, when one of the system components is updated and changes have to be effected on the fly, it creates additional work load of a disproportionate level in an organization (i. e., when Microsoft upgrades its desktops from the Windows XP to Windows Vista operating system, thousands of PCs need to be worked on over a weekend).

Implementing a packaged solution is also a difficult process. Existing system functionality and processes have to be mapped onto the functionality and process structure of the package. If they differ substantially, the firm has to decide between a quick implementation with minimal changes to the package (but large internal changes to the organization, including retraining) and substantial modification to the package to align it with existing processes (thereby delaying installation by many months). Converting data from an old system to the requirements of the new system is an added and significant work element in this scenario.

Service providers have evolved numerous tools to automate many of the tasks involved; for example, when moving over a set of applications from IBM COBOL to Unisys COBOL, Tata Consultancy Services (TCS) developed a series of software filters which, when applied sequentially, accomplished the conversion to almost 80%. Hence the manual effort required came down substantially. Developing libraries, subroutines, and other reusable components has been a standard technique among bespoke service providers. The well-known Y2K bug created a huge one-off service opportunity for them. It was successfully executed by creating software factories where hundreds of programmers used tools to detect and rectify the error. Similarly SAP and other package implementers have excelled in developing templates that are specific to industries. These templates cut down implementation time dramatically.

Remote diagnostic and repair services will come into play in the future. Sophisticated tools facilitate simulation of error conditions offsite and identification of environmental conditions that cause system failure. When object-oriented systems are fully functional then, with remote access, the defective component can be removed and the properly functioning component bound to the system. Acceptance testing can also be performed from afar. The industry is aspiring to automate these functions in the coming decades.

71.4.4 Network and Security Management

Computer networks consist of not only processors but storage devices, routers, printers, sensors, etc. These are not mere hardware devices but contain embedded or loadable software too. They have grown in size and complexity from local to wide to metropolitan area networks. Their scope and coverage has been extended from the corporate to mass segment with the inclusion of PCs. Laptops, smart mobile phones, and devices such as Blackberry and the IPhone with their ubiquitous Internet connectivity have stretched the network delivery and management challenges to higher orbits. An example is shown in Fig. 71.6.

Clemm [71.33] defines network management to encompass activities, methods, procedures, and tools that pertain to the operation (running the network), administration (managing network resources), maintenance (repair and upgrade), and provisioning (intended use assurance) of networked systems. Usage monitoring, resource logs, device simulations, and agents deployed on infrastructure form the data sources for network management. Cisco systems, a leader in networking management, provides many tools for performing these functions [71.34].

Networks are differentiated in terms of the topology (line, bus, star, hub and spoke, tree, etc.) that defines the logical or physical connection between the devices, network protocols containing a language of rules and conventions for communication between network devices (hypertext transfer protocol (HTTP), transmission control protocol/Internet protocol (TCP/IP), simple mail transfer protocol (SMTP), etc.), and standards facilitating interoperability. Designing a specific network for a given role is a function of the involved devices, their locations and cost, and many other specifications.

Managing networks for performance is mission critical. However, no network can function without embedding security considerations throughout. Security concerns cover access rights, person authentication, and transaction validity at a person level and the threat of viral attacks, intrusion of spies, and denial of service (DoS) at a macro level [71.35].

Every system defines who is a legitimate user and what usage rights the person has; for example, a transport department employee may have access to the names of employees in all other departments of

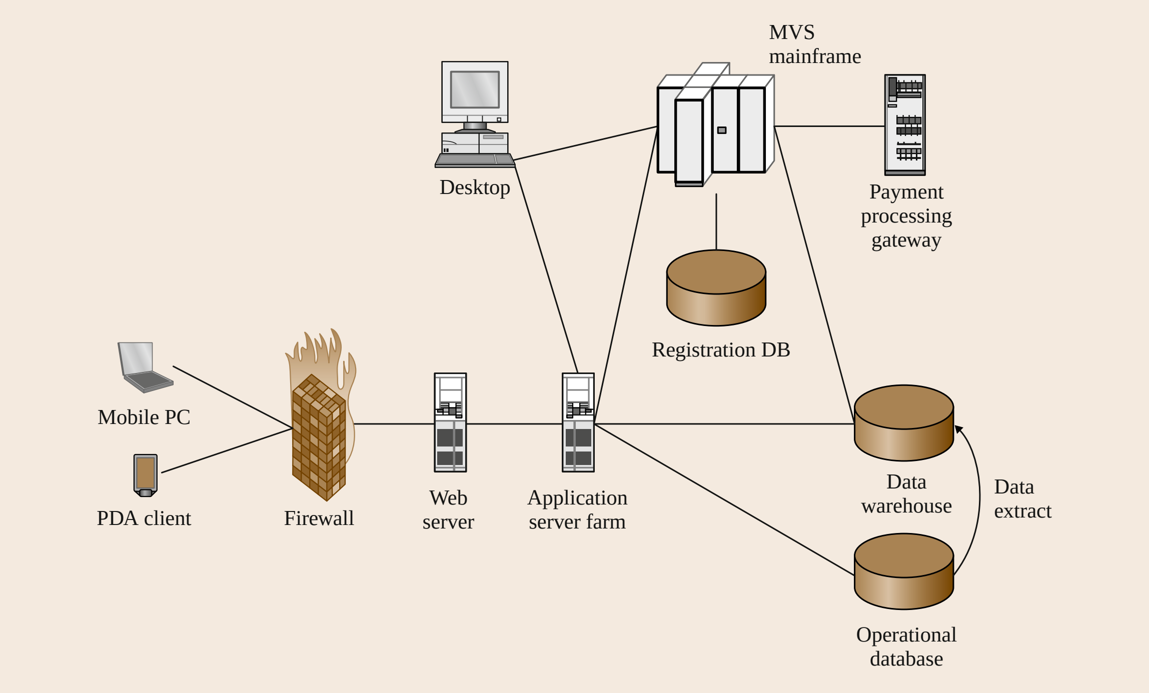

Fig. 71.6 Network diagram for the university system (after [71.36])

the firm but not to their personal details. A customer may do an online query about the account balance in a bank account but may not be authorized for online funds transfer. Over the years these requirements have extended to time of day and location too. Certain transactions cannot be performed outside office hours and cannot be executed from a nondesignated place or terminal even within office hours. Likewise, denial of legitimate access can also invite trouble to the organization. It then becomes the responsibility of the system to ensure that access rights are adhered to. Users, locations, and devices are assigned unique identities (IDs) to ensure this.

The second aspect of security is person authentication. One has to ensure that the system is being accessed only by the authorized person and by no-one else. Protection against impersonation is the key concern. Earlier systems relied heavily on passwords associated with each identified user (user ID). Password protection systems have been strengthened over the years. Frequent change in password is mandated along with selection of passwords that are difficult to guess. At the next level, systems seek additional personal details (such as date of birth) to validate the person's identity. These are found to be inadequate in modern systems. Impressive advancement in signature recognition and fingerprint (a biometric) recognition technologies has enabled firms to integrate these devices into computer systems. Voice print is used in some cases to validate identity [71.37].

Transaction validity facilitates fraud prevention. A separate password is associated with the transactions and nowadays a one-time key is generated specific to each transaction. After use, the key is destroyed. Digital certification technology has come into play to authenticate the combination of person and transaction relating to transmitted documents. One of the most significant inventions is the encryption mechanism. Data is encoded prior to transmission over a network and decoded at the final point. Seminal work has been done by RSA [71.38] in designing and implementing a public-key approach. Encryption standards have emerged and are being mandated for critical transactions.

Vendors and products have flooded the market with services for virus protection and intrusion prevention. Firewalls are being built at various levels to filter out unwanted visitors. The black list is no longer static; it is updated dynamically by most vendors. New upgrades or patches are issued routinely to protect against emerging new threats. It has become a legal necessity to subject most systems to a periodic security audit and to obtain a compliance certification.

The developments for further automation have progressed along the biometric path [71.39]. Eye or facial feature recognition and their combination with fingerprints are coming into play. Pattern recognition algorithms are becoming sophisticated. Sharing of data about events, impersonators, and system loop holes or bugs is being attempted within select special interest groups. Other attempts cover mapping data from disparate systems and intervening and filtering suspected transactions.

An interesting development has been the research efforts directed towards psychological profiling of the imposters and cybercriminals. Many of them seem to be technology savvy, young, and motivated by altogether different reasons compared with other types of criminals. Hacker conventions are held annually to learn from them and to recruit experts among them to provide protection services.

71.4.5 Hosting and Infrastructure Management

IBM, the industry leader, preferred to lease the services of its hardware, software, and human resources in the formative years. This practice continued for nearly two decades and was followed by its competitors as well. However the unbundling phenomenon, as it took roots, encouraged firms to own the equipment, license the software, and build in-house teams for system development and maintenance. The entry of mid-range systems in the 1970s and the proliferation of PCs from the 1980s gave further impetus to this trend; however not for long.

Many large enterprises found that the tasks of selecting the hardware, upgrading the software, and recruiting and retaining staff were draining management resources. They were caught between decisions to go for centralized versus distributed systems, to select best-of-breed solutions or integrated suite of applications, and to insource or outsource application maintenance function over the years. The rapid pace at which firms in multiple industries were merging or acquiring others compounded these management issues. Multiple contracts with multiple vendors had to be negotiated often, large volumes of data had to be often merged or migrated, and it was difficult to hold any individual service provider responsible when failure occurred.

Soon they also realized that information technology is a service function, essential for their survival, and sometimes an enabler of competitive advantage, but not their core activity. The retail chain had to focus on customer acquisition and retention while the financial services firms had the challenge of product innovation. They opted to outsource the IT function in part or full. Thus a market opportunity was created for firms with expertise in managing IT infrastructure.

The infrastructure usually consists of processors, storage units, printers, desktops, networking equipment such as routers and switches, security devices, power supply sources, voltage regulators, surge protectors, etc. It could include operating personnel too. This opportunity is aggressively pursued by many large vendors, extending their services to data center management as well [71.40]. Firms had the advantage of signing one contract with the infrastructure management services (IMS) service provider instead of many contracts with multiple vendors, service providers, contractors, etc. There was further flexibility in owning versus not owning the equipment to the client firms.

Automation has a central role to play in IMS. The agreement between the client firm and the service provider is governed by a service-level agreement (SLA) that calls for device uptime on a category basis and transaction response time on a type basis. Implementation of the monitoring, reporting, and managing functions related to SLAs is automated to a high degree. Many times, self-diagnostic and repair tasks are performed by the respective devices through sophisticated software.

The Internet has added a major dimension to this field. Until its arrival IMS was popular only in large commercial firms. Now, in a new avatar called web hosting, IMS has reached out to small and medium-sized enterprises (SMEs) and the masses. Today, it is estimated to be a multibillion-dollar market. Hosting is a subset of IMS. The server equipment can be installed anywhere geographically (typically on the premises of the host firm), and the Internet or private network is leveraged to provide services to client firms and end customers of client firms seamlessly. Normal web services include email, static pages, help desk, auction sites, etc. IBM, the largest web hosting service provider globally, has included managed events such as Wimbledon, the Grammy Awards, and the Ryder Cup within this service ambit [71.41].

Web hosting services rely almost 100% on web and automated tools to perform their roles. Specialist software firms write the required application for web hosting to cover performance, content delivery, and security aspects. The need for a hosting and IMS service provider to tie together multiple products is apparent when we note that IBM's service portfolio embraces Equinix, ATT, Akamai Technologies, Keynote Systems, Cisco, i2, Ariba, and others [71.41].

Web-hosted services often cross international borders. A customer living in London can be accessing a US car company site hosted in Ireland to order an accessory. Countries often debate over the territorial rights of such transactions and try to figure out who sold what to whom.

Both IMS and hosted services are evolving with technological advancement and globalization. They are spinning out new business models. Pay per transaction (including software as a service (SaaS) [71.42]) as opposed to ownership of devices and resources is emerging. As it gains acceptance, automation of such services has to include robust mechanisms for service accounting, billing, and receivable management on the business side, and transaction integrity, authenticity, and nonnegation aspects on the technical side.

71.5 Impact Analysis

Computers and IT-based services are not mere automation aids that enhance resource productivity. Their impact on corporations and society is deep and wide. They have created new channels, markets, products, labor markets, and business paradigms. The have also had societal impact in terms of higher level of transparency and fairness, and helped to eliminate system leakages and root out corruption in many countries. At an individual level they have changed perceptions, altered human behavior, enhanced aspirations, and acted as catalysts to feed the innovative spirit of humanity.

With direct access to the Internet to every customer or stakeholder a new channel of delivery has been opened up. It has the advantage of low cost, high reliability, and asynchronous communication possibility. With the convergence of technology, the Internet as a channel is also the most cost-efficient means of delivering data, text, voice, and images. Companies face a wide range of options in terms of how they wish to leverage this channel. Many traditional organizations, including banks such as ICICI in India, have chosen to use it as the primary vehicle for service delivery.

Newer products have emerged to meet both primary and secondary needs. The iPod delivers digital music and in the process has eliminated all intermediate storage media such as compact discs (CDs) and digital versatile discs (DVDs). Books need not be printed anymore as their content can be digitally delivered. GPS-based navigation systems guide travelers to their destinations. Confidential delivery of sensitive and business-critical documents through the Internet has created the demand for digital certification and person identification services.

Newer markets for teleconferencing, online auctions, buyer–seller meet, and telemedicine have emerged. Further finer segments of the markets to cater for the needs of aged, handicapped or people on the move have been created.

Information asymmetry in earlier society created many intermediary roles that facilitated bridging between supply and demand sides. These have been destroyed in the Internet age. Any new role can emerge now only on the strength of demonstrable value. Consequently enhanced skill levels have to be closely related to market needs. An effective example of this is the role of distributors and retailers as intermediaries. They bridged the communication gap between the manufacturer and end customer while moving goods across the supply chain effectively. The Internet has limited their role as a communicator. Consequently they need to excel in providing comparative value of goods from different manufacturers to enhance their value proposition to end customers.

Since many tasks can be executed unbounded by geography, outsourcing has crossed international borders with ease and has created employment opportunities for millions in developing countries. Concerns about the ramifications of this for jobs in developed countries have emerged [71.43]. However, the market for high-end products and services has expanded globally due to rising affordability in emerging economies.

The emergence of new business models is noteworthy. Fixed costs are presented as variable costs, thus altering investment requirements. Development costs are overshadowed by marketing and customer reach costs. The economics of the information society is very different from that of the engineering society. Companies have to make an appropriate transition to ensure their survival and growth

With individuals, face-to-face interaction has been replaced with virtual meetings, sequential exchanges are now concurrent, and judgment or wisdom, if not supported by data and evidence, is not accepted. New paradigms have emerged in interactive behavior. Age as a proxy to accumulated knowledge is no longer revered.

Governments have been aggressive in introducing Internet-based services to reach out to the citizens. Apart from filing tax returns, registration of land records and motor vehicles, disbursal of pension funds, updating voter registry, and government-to-business transactions fall within the purview of eGovernance. When implemented, these initiatives have made operations faster and more cost effective and have rooted out sources of corruption in many instances.

The impact on society at large, with respect to volunteer activities, is explored in [71.44]. The legislative support required for use of information technology to the physically disadvantaged is documented in [71.45].

The societal impact of computers, the Internet, and information technology is even more significant when we transcend the corporate sector. Facebook and LinkedIn are Internet-based networks of special-interest groups that demonstrate what viral growth is all about. YouTube has given the world on a platter as a platform to showcase one's talent at virtually no cost. These developments are altering many paradigms that we have grown up with.

71.6 Emerging Trends

As stated earlier technology convergence, real-time analytical processing, digital delivery of integrated and multimedia information, and software as a service (SaaS) are the visible trends within the information and technology services industry. Web services are leading to services-on-demand (SoD) business models. Both SaaS and SoD are rewriting business models by converting fixed costs to variable costs. It makes eminent business sense to adopt these models at the early growth stages of a firm and then switch over to the traditional ownership model when the firm has reached a higher sales volume. The entire IT infrastructure consisting of bundled hardware, software, and services is treated akin to a utility [71.46] that is essential for business operations but may not bestow any competitive advantage. The later can come only through market and product innovations and analytics.

In the scientific community, a model that is being tested is grid computing [71.47]. It is focused on leveraging the widely dispersed processing power of the Internet for faster execution of complex and time-consuming calculations. Weather forecasting and genetic mapping fall into this domain. Geographical information systems (GIS) that combine location maps with other attributes are already common [71.48]. Multilayering of GIS and recognizing patterns for effective design of systems is on the anvil.

Computer animation services are poised for a giant leap with sophisticated tools and high-speed devices. Movie production and postproduction work, integrated with special effects, is being automated at a relentless pace by companies such as Pixar and DreamWorks. Simulation combined with animation is turning out niche products such as factory layout and work flow sequencing for the manufacturing industry.

Object-oriented design awaits the development of completely interchangeable, plug-and-play components for corporate functions. It will then be coupled with automated and remote diagnostics, repair, testing, and maintenance services.

Legal acceptance of digitally filed documents in place of printed matter is growing worldwide. Standards are being enacted and enabling legislation is being introduced in many countries. Cross-border transactional validity and resolution of attendant tax issues is complex. It is expected that the *digital highway* will become integral to many aspects of human life when these challenges are tackled. The day is not far off when every legal entity, be it a person or a firm, has a unique digital identity, although this is likely to happen faster in some nations compared with others.

72. Library Automation

Michael Kaplan

Library automation has a rich history of 130 years of development, from the standardization of card catalogs to the creation of the machine-readable cataloging (MARC) communications format and bibliographic utilities. Beginning in the early 1980s university libraries and library automation vendors pioneered the first integrated library systems (ILS). The digital era, characterized by the proliferation of content in electronic format, brought with it the development of services for casual users as well as scholarly researchers – services such as OpenURL linking and metasearching and library staff tools such as electronic resource management systems. Libraries are now reacting to user demands for quick, easy, and effective discovery and delivery such as those they have grown accustomed to through the use of Google and other Internet heavyweights, by developing a new series of Library 2.0-based discovery-to-delivery (D2D) applications. These newest offerings deliver an up-to-date user experience, allowing libraries to retain their back-office systems (e.g., acquisitions, cataloging, circulation) and add to or replace them as needed. In the process libraries can leverage Web 2.0 services to interconnect systems from different vendors and thereby ensure a gradual transition toward a new automation platform.

72.1 In the Beginning: Book Catalogs and Card Catalogs

In many ways one can date the beginning of post-industrial era library automation to the development of the library catalog card and the associated card catalog drawer [72.1, 2]. The nature of the original library catalog card can be gleaned from this patent description of the so-called continuous library catalog card that had evolved to take advantage of early computer-area technology by the 1970s [72.1]:

> *a continuous web for library catalogue cards having a plurality of slit lines longitudinally spaced* 7.5 cm *apart, each slit line extending* 12.5 cm *transversely between edge carrier portions of the form such that upon removal of the carrier portions outwardly of the slit lines a plurality of standard* 7.5 cm × 12.5 cm *catalogue cards are provided. Longitudinally extending lines of uniquely shaped feed holes or perforations are provided in the carrier*

Fig. 72.2 Example of OCLC-produced catalog (shelflist) card (courtesy of OCLC [72.4])

> *portions of the form which permit printing of the cards by means of existing high speed printers of United States manufacture despite the cards being dimensioned in the metric system and the feed of the printers being dimensioned in the English system.*

Card catalogs and card catalog drawers are well described in this patent that pertains to an update to the basic card catalog drawer [72.2]:

> *an apparatus for keeping a stack of catalogue cards in neat order to be used, for example, in a library. If necessary, a librarian can replace a damaged catalogue card with a new one by just pressing a button at the bottom of the drawer to enable a compression spring to eject the metal rod passing through a stack of catalogue cards. Consequently, the librarian can freely rearrange the catalogue cards.*

Though these devices continued to evolve, the originals, when standardized at the insistence of Melvil Dewey in 1877, led eventually to the demise of large book catalogs, which, despite their longevity, were at best unwieldy and difficult to update [72.5]. As we will see later, the goal here was one of increased productivity and cost reduction, not that different from the mission espoused by late 20th century computer networks.

The development and adoption of the standard catalog card presaged the popular Library of Congress printed card set program that, together with a few commercial imitators, was the unchallenged means of universalizing a distributed cataloging model until the mid 1970s. The printed card set program, in turn, was succeeded by computerized card sets from the Ohio College Library Center (OCLC), later renamed the OCLC Online Computer Library Center, Inc.; the Research Libraries Group (RLG); and other bibliographic utilities. This was largely due to the advantage the utilities had of delivering entire production runs of card sets that could be both customized in format and at the same time delivered with card packs already presorted and alphabetized.

72.2 Development of the MARC Format and Online Bibliographic Utilities

The success of the bibliographic utilities coincided with several other developments that together led to today's library automation industry. These developments were the MARC communication format, the development and evolution of university homegrown and then vendor-based library systems, and finally the growth of the networking capabilities that we now know as the Internet and the World Wide Web. In fact, without the development of the MARC format, library automation would not have been possible. Taken as a whole, these milestones bookend 130 years of library automation.

Two extraordinary individuals, Henriette Avram and Frederick Kilgour, were almost single-handedly responsible for making possible library automation as we know it today. During her tenure at the Library of Congress, *Avram* oversaw the development of the MARC format; it emerged as a pilot program in 1968, became a US national standard in 1971, and an international standard in 1973 [72.6]. The MARC standard bore a direct connection to the development of OCLC and the other bibliographic utilities that emerged during the 1970s. RLG, the Washington Library Network (WLN), and the University of Toronto Library Automation System (UTLAS) all sprang from the same common ground.

Kilgour, who had served earlier at Harvard and Yale Universities, moved to Ohio in 1967 to establish OCLC as an online shared cataloging system [72.7]. OCLC now has a dominant, worldwide presence, serving over 57 000 libraries in 112 countries with a database that comprises in excess of 168 million records (including articles) and 1.75 billion holdings.

From the beginning the goals of library automation were twofold: to reduce the extremely labor-intensive nature of the profession while increasing the level of standardization across the bibliographic landscape. It was, of course, obvious that increasing standardization should lead to reduced labor costs. It is less clear that actions on the bibliographic "production room floor" made that possible. For many years these goals were a core part of the OCLC mission – the most successful modern (and practically sole surviving) bibliographic utility. Founded in 1967, OCLC is a [72.8]

> *nonprofit, membership, computer library service and research organization dedicated to the public purposes of furthering access to the world's information and reducing information costs.*

In the early years of library automation, libraries emphasized cost reduction as a primary rationale for automation.

In the early 1970s a number of so-called bibliographic utilities arose to provide comprehensive and cooperative access to a database comprised of descriptive bibliographic (or cataloging) data – now commonly known as *metadata*. One by one these bibliographic utilities have vanished. In fact, in 2007 OCLC absorbed RLG and migrated its bibliographic database and bibliographic holdings into OCLC's own WorldCat, thus leaving OCLC as the last representative of the utility model that arose in the 1970s.

A hallmark of library automation systems is their evolution from distinct, separate modules to large, integrated systems. On the level of the actual bibliographic data this evolution was characterized by the migration and merger of disparate files that served different purposes (e.g., acquisitions, cataloging, authority control, circulation, etc.) into a single bibliographic master file. The concept of such a master file is predicated on avoidance of duplicative data entry; that is, data should enter the system once and then be repurposed however needed. A truly continuous, escalating value chain of information, from publisher data to library bibliographic data, still does not exist. Libraries, especially national libraries such as the Library of Congress, routinely begin their metadata creation routines either at the keyboard or with suboptimal data (often from third-party subscription agents). (The Library of Congress also makes use of an electronic cataloging-in-publication program.) The online information exchange (ONIX) standard presages the ultimate extinction of the pure MARC communication standard as extensible markup language (XML)-based formats become dominant. Both the hardware/software and the data strains become ever-more intertwined as bibliographic automation becomes a subset of the larger information universe, adopting standards that transcend libraries.

72.2.1 Integrated Library Systems

The story of modern library automation began with a few pioneering individuals and libraries in the mid to late 1960s [72.9–13]. In addition to Avram and Kilgour, one of the more notable was Herman Fussler at the University of Chicago, whose efforts were supported by the National Science Foundation. Following the initial experiments, the university began to develop a new system, one of whose central concepts was in fact the bibliographic master file [72.9].

The University of Chicago was not alone. Stanford University (with bibliographic automation of large library operations using time sharing (BALLOTS)), the Washington Library Network, and perhaps most importantly for large academic and public libraries, Northwestern University (NOTIS) were all actively investigating and developing systems. NOTIS was emblematic of systems developed through the mid 1980s. NOTIS and others (e.g., Hebrew University's automated library expandable program (Aleph 100) that became the seed of Ex Libris and the Virginia Tech library system (VTLS)) were originally developed in university settings. In the 1980s NOTIS was commercialized and later sold to Ameritech in the heyday of AT&T's breakup into a series of Baby Bells. The NOTIS management team eventually moved on and started Endeavor Information Systems, which was sold to Elsevier Science and then in turn to the Ex Libris Group in 2006.

Other systems, aimed at both public and academic libraries, made their appearance during the 1970s and 1980s. Computer Library Services Inc. (CLSI), Data Research Associates (DRA), Dynix, GEAC, Innovative Interfaces Inc. (III), and Sirsi were some of the better known. Today only Ex Libris, III, and SirsiDynix (merged in 2005) survive as major players in the integrated library system arena.

The Harvard University Library epitomizes the various stages of library automation on a grand scale. Under the leadership of the fabled Richard DeGennaro, then Associate University Librarian for Systems Development, Harvard University's Widener Library keyed and published its manual shelflist in 60 volumes between 1965 and 1979 [72.14]. At the same time the university was experimenting with both circulation and acquisitions applications, the latter with the amusing moniker, computer-assisted ordering system (CAOS), later renamed the computer-aided processing system (CAPS). In 1975 Harvard also started to make use of the relatively young OCLC system. As with other institutions, Harvard initially viewed OCLC as a means to more efficiently generate catalog cards [72.15].

In 1983 Harvard University decided to obtain the NOTIS source code from Northwestern University to unify and coordinate collection development across the 100 libraries that constituted the vast and decentralized Harvard University Library system. The Harvard system, HOLLIS, served originally as an acquisitions subsystem. Meantime, the archive tapes of OCLC transactions were being published in microfiche format as the distributable union catalog (DUC), for the first time providing distributed access to a portion of the Union Catalog – a subset of the records created in OCLC. It was not until 1987 that the catalog master file was loaded into HOLLIS. In 1988 the HOLLIS OPAC (online public access catalog) debuted, eliminating the need for the DUC [72.15].

It was, in fact, precisely the combination of the MARC format, bibliographic utilities, and the emergence of local (integrated) library systems that together formed the basis for the library information architecture of the mid to late 1980s. Exploiting the advantages presented by these building blocks, the decade from 1985 to 1995 witnessed rapid adoption and expansion in the field of library automation, characterized by maturing systems and increasing experience in networking. Most academic and many public libraries had an integrated library system (ILS) in place by 1990. While the early ILS systems developed module by module, ILS systems by this time were truly integrated. Data could finally be repurposed and reused as it made its way through the bibliographic lifecycle from the acquisitions module to the cataloging module to the circulation module. Some systems, it is true, required overnight batch jobs to transfer data from acquisitions to cataloging, but true integration was becoming more and more the norm.

By the early 1990s libraries were entering the age of content. Telnet and Gopher clients made possible the online presence of abstracting and indexing services (A&I services). Preprint databases arose and libraries began to mount these as adjuncts to the catalog proper. DOS-based Telnet clients gave way to Windows-based Telnet clients. Later in the 1990s, Windows-based clients in turn gave way to web browsers.

All this time, the underlying bibliographic databases were largely predicated on current acquisitions. The key to an all encompassing bibliographic experience lay in retrospective conversion (Recon) as proven by Harvard University Library's fundamental commitment to Recon. Between 1992 and 1996 Harvard University added millions of bibliographic records in a concerted effort to eliminate the need for its thousands of catalog card drawers and provide its users with complete online access to its rich collections. Oxford University and others soon followed. While it would be incorrect to say that Recon is a product of a bygone era, most major libraries do indeed manage the overwhelming proportion of their collection metadata online. This has proven to be the precursor to the massive digitization projects underwritten by Google, Yahoo, and Microsoft, all of which depend to a large degree on the underlying bibliographic metadata, much of which was consolidated during the Recon era.

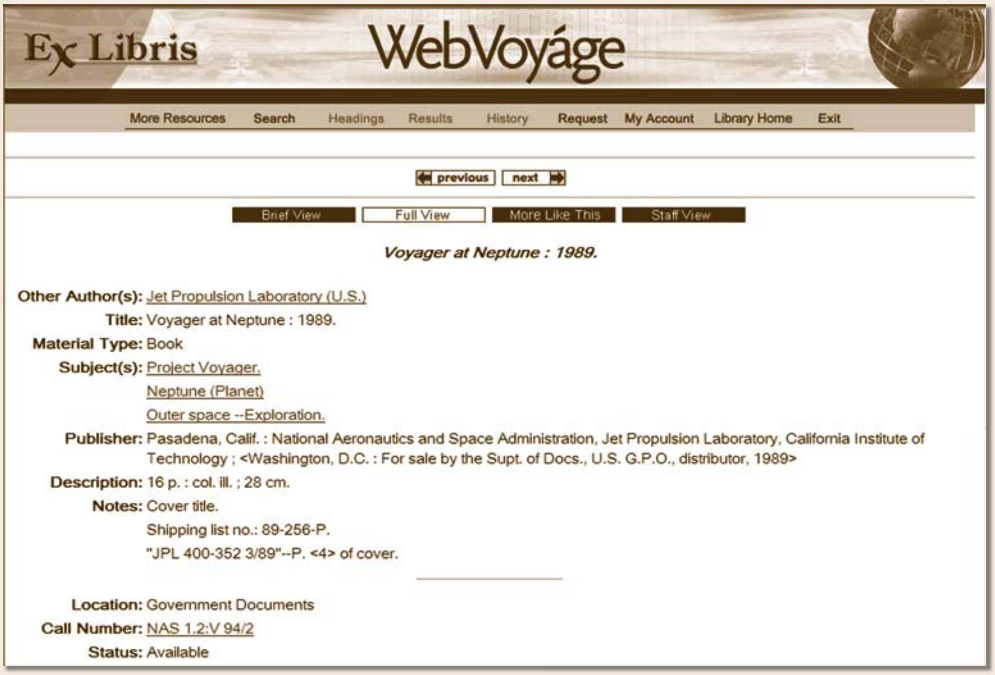
In the early years of library automation, library systems and library system vendors moved from time-sharing, as was evident in the case of BALLOTS, to large mainframe systems. (Time-sharing involves many users making use of time slots on a shared machine.) Library system vendors normally allied themselves with a given hardware provider and specialized in specific operating system environments. The advent of the Internet, and more especially the World Wide Web, fueled by the growth of systems based on Unix (and later Linux) and relational database technology (most notably, Oracle) – all combined with the seemingly ubiquitous personal computer – gave rise to the second generation in library automation, beginning around 1995. As noted, the most visible manifestation of that to the library public was the use of browsers to access the catalogs. This revolution was followed within 5 years by the rapid and inexorable rise of e-Content. The most successful library automation vendors, it is now clear, are those that possessed a clear and compelling vision for combining library automation with delivery of content. The most successful of those vendors also espouse an e-Content philosophy that is publisher neutral.

72.2.2 Integrated Library Systems: The Second Generation

Libraries, often at the direction of their governing bodies, made a generational decision during this period to migrate from mainframe to client–server environments. Endeavor Information Systems, founded with the goal of creating technology systems for academic, special, and research libraries, was first out of the starting blocks and had its most successful period for about a decade following its incorporation in 1994 [72.16]. It was no accident, given its roots in NOTIS and its familiarity with NOTIS software and customers, that Endeavor quickly captured the overwhelming share of the NOTIS customer base that was looking to move to a new system. This was particularly true in the period immediately preceding the pivotal year 2000, when Y2K loomed large. In planning for the shift to the year 2000 library computer systems faced the same challenge all other legacy computer faced, namely, reworking computer code to handle calendar dates once the new millennium had begun. So many libraries, both large and small, had to replace computer systems in the very late 1990s that 1998 and 1999 were banner years in the library computer marketplace, followed by a short-term downturn in 2000.

Ex Libris Ltd., a relative latecomer to the North American library market, was founded in Israel in 1983, originally as ALEPH Yissum, and commissioned to develop a state-of-the-art library automation system for the Hebrew University in Jerusalem. Incorporated in 1986 as Ex Libris, a sales and marketing company formed to market Aleph, Ex Libris broke into the European market in 1988 with a sale to CSIC, a Spanish network of 80 public research organization libraries affiliated with the Spanish Ministry of Science and Technology. This sale demonstrated an early hallmark of Aleph, namely deep interest in the consortial environment.

At roughly the same time as Endeavor was releasing its web-based client–server system, Voyager, Ex Libris released the fourth version of the Aleph system,



Voyager at Neptune : 1989.

Aleph 500. Based on what was to become the industry standard architecture, Aleph featured a multi-tier client–server architecture, support for a relational database, and – a tribute to its origins and world outlook – support for the unicode character set. Starting in 1996, with Aleph 500 as its new ILS stock-in-trade, Ex Libris created a US subsidiary and decided to make a major push into the North American market. At the same time – and crucially for its success in the emerging e-Content market – Ex Libris made the strategic commitment to invest heavily in research and development with the stated goal of creating a unified family of library products that would meet the requirements of the evolving digital library world.

72.2.3 The Nonroman World: Unicode Comes to Libraries

If there is a single accepted analysis of the state of libraries and library automation in the 21st century, it is the fact the library world is but one part of the much larger information universe and that library standards, e.g., the MARC format and the American standard code for information interchange (ASCII) character set, need to be considered in light of the larger universe of information standards, such as XML (ONIX) and unicode. Those libraries and library vendors that have the most robust understanding of this fundamental shift have been most adept at long-term survival.

72.3 OpenURL Linking and the Rise of Link Resolvers

The shift from ASCII to unicode and from MARC to XML heralded an entire salvo of digital products that introduced a new concept of library automation – the ILS was no longer the be all and end all of library automation – and was marked by Ex Libris's release of SFX. SFX was developed in conjunction with Herbert Van de Sompel (presently a research scientist at the Los Alamos National Laboratory) and the Universiteit Ghent in response to what is known as the *appropriate copy* problem [72.17]:

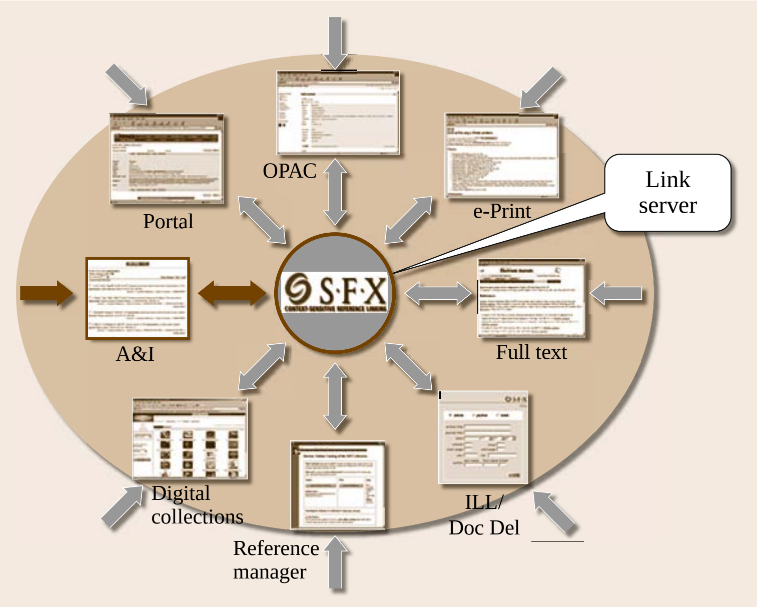

Fig. 72.5 SFX and OpenURL linking (after [72.4])

> *There has been an explosive growth in the number of scholarly journals available in electronic form over the internet. As e-Journal systems move past the pains of initial implementation, designers have begun to explore the power of the new environment and to add functionality impossible in the world of paper-based journals. Probably the single most important such development has been reference linking, the ability to link automatically from the references in one paper to the referred-to articles.*

Led by Oren Beit-Arie (presently Ex Libris's chief strategy officer), SFX (which stands for *special effects*) was not only a commercial success but also became generically associated with the standard known as OpenURL linking. In much the same way as Xerox is synonymous with photocopying, so SFX has become synonymous with context-sensitive linking. Released in 2000, SFX now has an installed base of over 1500 libraries and research centers worldwide

Librarians, especially systems librarians, are well known as staunch proponents of standards. Thus it was an extremely astute move when Ex Libris took the initiative to have the National Information Standards Organization (NISO) adopt the OpenURL as a NISO standard.

The OpenURL framework for context-sensitive services was actually approved on a fast-track basis as ANSI/NISO Z39.88 in 2005 [72.18]:

> *The OpenURL framework standard defines an architecture for creating OpenURL framework applications. An OpenURL framework application is a networked service environment, in which packages of information are transported over a network. These packages have a description of a referenced resource at their core, and they are transported with the intent of obtaining context-sensitive services pertaining to the referenced resource. To enable the recipients of these packages to deliver such context-sensitive services, each package describes the referenced resource itself, the network context in which the resource is referenced, and the context in which the service request takes place.*

72.3.1 Metasearching

Ex Libris quickly followed its success with SFX by expanding into the area of metasearching. Also known as federated searching, metasearching was another response to the proliferation of online journals and online content. MetaLib (and competing products) were the initial bibliographic answer to the problem posed by commercial search engines such as Yahoo or Google, namely that much content had come quickly to live outside the realm of the library catalog. Metasearch enables users – power and nonpower users, whether the general public or undergraduates, graduate students, post-doctoral students, and faculty – to retrieve the

Fig. 72.6 Boston College MetaQuest, with quick sets

most comprehensive set of results in a single search, including traditional bibliographic citations, abstracting and indexing service information, and the actual fulltext whenever it is available. Before long, numerous offerings of both OpenURL link resolvers and metasearch applications were available in the bibliographic arena.

By 2005 many institutions had made their primary bibliographic search gateway not the library catalog, but their metasearch application. Boston College is a good example. Its library catalog, Quest, is but one of the numerous targets searchable through its metasearch application, MetaQuest.

By now libraries and their users had bought wholeheartedly into the combination of metasearching and linking – it is the combination of these two approaches for dealing with the e-Content universe that makes them together vastly more powerful than either alone. Troubles loomed, though, in the absence of standards for metasearching. NISO once again stepped forward and created the NISO Metasearch Initiative. NISO described the challenge as [72.19]:

> *Metasearch, parallel search, federated search, broadcast search, cross-database search, search portal are a familiar part of the information community's vocabulary. They speak to the need for search and retrieval to span multiple databases, sources, platforms, protocols, and vendors at one time. Metasearch services rely on a variety of approaches to search and retrieval including open standards (such as NISO's Z39.50), proprietary API's, and screen scraping. However, the absence of widely supported standards, best practices, and tools makes the metasearch environment less efficient for the system provider, the content provider, and ultimately the end-user.*

Standards are invaluable, but in the library world standards – aimed at providing consistency in searching – are all the more important. As knowledge seekers move from one environment to the next with the change of a uniform resource locator (URL), they also expect consistent behavior across these various information environments. It is particularly encouraging, therefore, to see how the public responds. An article in the October 7, 2005 *Harvard Crimson* shows the opinion of a student at one of the world's most prestigious universities [72.20]:

> *Of the many things to change at Harvard over the summer...there is one new development that students may not have noticed but that come term-paper time will make a world of difference. That change is the switch from Harvard University Library's (HUL) e-Resources website to the new e-Research @ Harvard Libraries website. HUL has done a tremendous job with the new easy-to-use site,*

> *and we applaud them for dreaming up such a helpful resource.*
>
> *The new e-Research page puts a high-tech user interface on top of Harvard's vast array of online subscriptions, making resources more readily accessible – whether users know the exact journal they are looking for or are just poking around for sources. But the best thing about the new e-Research page is the plethora of features it provides that take full advantage of computers to make research easier … within seconds you can find what you are looking for, either in fulltext online or a Find it @ Harvard button that tells you exactly where in Harvard's huge library system to look.*

Within two short paragraphs two of the major tools of 21st century librarianship and e-Scholarship emerge: metasearching (e-Research) and OpenURL linking (Find It @ Harvard). The library catalog (HOLLIS) is mentioned, too, but it is but one amid a vast array of electronic resources. Looming over all this is the specter of Google, whose seemingly endless series of innovations and content-related initiatives is in turn pushing the frontiers of automation within the library systems world itself.

72.3.2 The Digital Revolution and Digital Repositories

Three other areas of institutional bibliographic automation were under discussion and development between 2002 and 2007: digital repositories, electronic resource management systems, and new models of resource discovery and delivery.

As with early developments in library automation, one of the first efforts to manage digital objects, especially textual objects, began in a university environment. In 2000 the Massachusetts Institute of Technology Libraries and Hewlett-Packard embarked on a joint research project that we now know as DSpace – an early digital asset management (DAM) system.

DSpace introduced the concept of an institutional repository (IR) [72.21],

> *a robust, software platform to digitally store… collections and valuable research data, which had previously existed only in hard copies…an archiving system that stores digital representations of analog artifacts, text, photos, audio and films…capable of permanently storing data in a non-proprietary format, so researchers can access its contents for decades to come.*

DSpace is an open-source software toolkit. Automation vendors realized this was a fertile field for institutions not inclined to go the toolkit approach. Various products have emerged; notable among them are CONTENTdm, developed at the University of Washington and now owned by OCLC; and Ex Libris's DigiTool. An open-source newcomer to the field is Fedora, which will likely appeal to the same group of libraries interested in DSpace [72.22]. All these products are designed for deposit, search, and retrieval. While they have maintenance aspects about them, they are not true preservation systems.

Libraries and archives, as recognized custodians of our intellectual and cultural heritage, have long understood the value of preservation and ensuring longitudinal access to the materials for which they have accepted custodianship. As more and more materials are digitized, particularly locally important cultural heritage materials, or are born digital, these institutions have begun to accept responsibility for preserving these materials. Recently (2007) the National Library of New Zealand leapt to the forefront of digital preservation by developing a National Digital Heritage Archive (NDHA) program to ensure the ongoing collection, preservation, and accessibility of its digital heritage collections. This multiyear program, begun in conjunction with Endeavor Information Systems and continued by Ex Libris, aims to preserve digital objects for nothing less than the life of the custodial bodies [72.23].

72.3.3 Electronic Resource Management

On the serial side of the bibliographic house, the e-Journal evolution of the 1990s turned rapidly into the e-Journal avalanche of the 21st century. Libraries and information centers that subscribed to thousands or tens of thousands of print journals found themselves facing a very different journal publication model when presented with e-Journals. Not only have libraries had to contend with entirely new models – print only, print with free e-Journal, e-Journal bundles or aggregations, often in multiple flavors from competing publishers and aggregators – but also these e-Journals came with profoundly different legal restrictions on use of the e-Content. Libraries found themselves swimming upstream against a rushing tide of e-Content. A number of institutions (among them Johns Hopkins University, Massachusetts Institute of Technology, and the University Libraries of Notre Dame) developed homegrown systems to contend with the morass; most others relied on spreadsheets and quantities of paper.

Into this fray stepped the Digital Library Foundation (DLF), which convened a small group of e-Journal and e-Content specialists to identify the data elements required to build an electronic resources management (ERM) system. This study, developed in conjunction with a group of vendors and issued in 2004 as *Electronic Resource Management: Report of the DLF ERM Initiative (DLF ERMI)*, was one of the few times since the development of the MARC standard that a standard predated full-blown system development [72.24].

Systems developers adopted the DLF ERMI initiative to greater or lesser degrees as dictated by their business interests and commitment to standards. Unlike the OpenURL link resolvers and metasearch tools, electronic resource management tools addressed an audience that was primarily staff, harking back to the original goal of library automation: to make librarians more productive.

Innovative Interfaces Inc. was the first vendor to release an ERM product. Serials Solutions, one of the newer players, whose origins lay in providing catalog copy for e-Journals and A-to-Z lists for e-Journals, has the 360Resource Manager offering.

72.3.4 From OPAC to Next-Generation Discovery to Delivery

A deeply held tenet of librarians is that they have a responsibility to provide suitably vetted, authoritative information to their users. In the years since the rise of Google as an Internet phenomenon, librarians have shown enormous angst in the reliance, particularly among the generation that has come of age since the dawn of the Internet, on whatever they find in the first page of hits from any of the most popular Internet search engines. Critical analysis and the intellectual value of the resulting hits are less important to the average user than the immediacy of an online hit, especially if it occurs on the first results page. Libraries continue to spend in the aggregate hundreds of millions of dollars on content, both traditional and electronic, yet have failed to retain even their own tuition-paying clientele.

OCLC, to its credit, confronted the issue head on with a report it issued in 2005 [72.25]. In the report OCLC demonstrates quite conclusively that ease of searching and speedy results, plus immediate access to content, are the most highly prized attributes users desire in search engines. Unfortunately, the report shows that libraries and library systems rank very low on this scale. On the other hand, when it comes to a question of authoritative, reliable resources, the report shows that libraries are clear winners. The question has serious implications for the future of library services. How should libraries and library system vendors confront this conundrum?

The debate was framed in part by a series of lectures that Dale Flecker, associate director of the Harvard University Library for Planning and Systems, gave in 2005 on: OPACS and our changing environment: observations, hopes, and fears. The challenge he framed was the evolution of the local research environment that comprises multiple local collections and catalogs. Harvard University, for example, had (and still has) separate catalogs for visual materials, geographic information systems, archival collections, social science datasets, a library OPAC, and numerous small databases. Licensed external services have proliferated: in 2005 Harvard had more than 175 search platforms on the Harvard University Library portal – all in addition to Internet engines, online bookstores, and so forth. Flecker expressed hope that OPACs would evolve to enable greater integration with the larger information environment. To achieve this, OPACs (or their eventual replacements) would have to cope with both the Internet and the explosion of digital information that was already generating tremendous research and innovation in search technology. Speed, relevance (ranking), and the ability to deal with very large results sets would be the key to success – or failure [72.26].

Once again, the usual series of library automation vendors stepped up. In truth, they were already working on their products but this time they were joined by yet another set of players in the library world. North Carolina State University adopted Endeca [72.27], best known as a data industry platform, to replace its library OPAC: "Endeca's unique information access platform helps people find, analyze, and understand information in ways never before possible" [72.27]. As the NCSU authors *Antelman* et al. noted in the abstract to their 2006 paper [72.28],

> *Library catalogs have represented stagnant technology for close to twenty years. Moving toward a next-generation catalog, North Carolina State University (NCSU) Libraries purchased Endeca's Information Access Platform to give its users relevance-ranked keyword search results and to leverage the rich metadata trapped in the MARC record to enhance collection browsing. This pa-*

> *per discusses the new functionality that has been enabled, the implementation process and system architecture, assessment of the new catalog's performance, and future directions.*

Other new players have also entered the market for new library delivery systems, generally called NextGen or discovery-to-delivery (D2D) systems. AquaBrowser is another example of a pure-OPAC replacement with no pretensions of replacing the complete range of ILS functions. Among more traditional library vendors, Innovative Interfaces has released its product, Encore (http://www.iii.com/encore), and Ex Libris its product, Primo (http://www.exlibrisgroup.com/primo.htm). Both were developed with a group of partners and both tout a one-stop solution for the discovery and delivery of information.

Ex Libris's choice of development partners was perhaps the more atypical in that one of its partners, Vanderbilt University, was particularly keen to use Primo to combine its library catalog, Acorn, with a facility to enable easy discovery and delivery of its unique Television News Archive [72.29]:

> *The Television News Archive collection at Vanderbilt University is the world's most extensive and complete archive of television news. The collection holds more than* 30 000 *individual network evening news broadcasts from the major US national broadcast networks: ABC, CBS, NBC, and CNN, and more than* 9000 *hours of special news-related programming including ABC's Nightline since 1989.*

The University of Iowa had a different goal, namely to push exposure of many of its otherwise isolated digital collections. These collections, which developed over time and throughout the institution, possess no native discovery interface and consequently suffer from a widespread lack of awareness. With Primo as its unifying discovery tool, the university can provide a single search interface to all of its rich collections. One notable example is the university's and the Iowa Historical Society's World War II newspaper clippings collection.

Fig. 72.7 Primo at the University of Iowa: an example of the new D2D paradigm

The Primo discovery and delivery system enables libraries to present their collections in an entirely new way, providing users with the ability to access a wealth of authoritative information from a single point. Central to the development of Primo has been the concept of *harvesting* and *publishing* as the means whereby a single, Google-like search interface can provide rapid and easy, normalized and enriched discovery for the entire range of resources under the control of the institution: local catalogs, locally digitized collections harvested by the open archieves initiative protocol for metadate harvesting (OAI-PMH) collections, and so forth. Primo is integrated with both metasearching (MetaLib) and OpenURL linking (SFX) to enable discovery in a vast range of external resources, with onward navigation and other services via the OpenURL syntax. In this way the institution can satisfy its users' desire for almost instantaneous response to simple queries while providing the ability to search a vast array of databases and e-Resources that are not held locally.

72.4 Future Challenges

Libraries and librarians have frequently stood at the forefront of the information revolution. The MARC format was a model of interinstitutional and international collaboration in its time. As libraries and their vendors evolved, though, large installed bases of customers and data made further change that much more challenging. At the same time, libraries became but one outpost on the information frontier. The growth of the Internet, the World Wide Web, and the rise of newer information industry players such as Google and Amazon have all combined to put libraries on the defensive. Libraries have now come to realize that standards such as unicode and XML can be exploited for their benefit by partaking of a global information chain. Librarians have come to grasp the significance of capturing information at its earliest stage and repurposing it throughout its lifetime, all the while continuing to add value to the information content package.

Almost 20 years after the advent of the integrated library system, we are witnessing the opening wedge in the dissolution of the ILS into a series of independent modules that communicate with each other by means of Web 2.0 services. These new discovery-to-delivery solutions are indeed, on the one hand, OPAC or OPAC-plus replacements and designed to work with a variety of vendor systems, but they are at the same time the first in a series of new library system modules that will likely appear over the next decade [72.30, 31]. As the industry continues to evolve, and as open systems respond to the demands of Web 2.0, we can expect the Integrated Library System to morph into a strategy based on the survival of the best-of-breed. The future will be one of distinct functional modules that communicate with one another by exploiting the concept of unified resource management (URM) [72.32].

Responding to the requirements and demands of the digital era, where e-Resources proliferate and dominate the publishing and acquisitions scene, the venerable ILS acquisitions and serials modules are already showing sings of coalescing around the ERM model. The ERM, with support for licensing and the other key attributes of e-Content, will replace the traditional systems which are oriented largely toward print and nonprint analogs (maps, kits, scores, sound recordings, etc.).

As the ILS gives way to the URM, and the URM becomes the predominant model for the third generation of library management systems, management of e-Content will no longer be an afterthought. The challenge for libraries, librarians, and vendors alike will be to develop a system, or perhaps a series of interconnected systems, that can inherently manage all manner of information content, both traditional and digital, and do it by exploiting both content and metadata from the very cradle of their existence.

73. Automating Serious Games

Gyula Vastag, Moshe Yerushalmy

In this chapter, we present the theoretical underpinnings of and conditions for learning through experiences gained in *immersive learning simulations* (or simply *gaming*) and show some examples of authentic learning experiences for business professionals. We argue that recent developments in the theory of knowledge acquisition coupled with changes in the educational landscape (e.g., the proliferation of online courses and programs) present an unrivalled and so far mostly unexploited opportunity for serious games. The examples presented are from using Managerial Enterprise Resource Planning (MERP) in a variety of MBA and corporate business training programs. Related examples of other virtual learning environments are also included.

73.1 Theoretical Foundation and Developments: Learning Through Gaming

It is widely accepted that "serious games are (digital) games used for purposes other than mere entertainment" [73.1]. *Michael* and *Chen* [73.2] give a similar definition: "A serious game is a game in which education (in its various forms) is the primary goal, rather than entertainment." The market for serious games is growing rapidly as more and more organizations are adopting or expected to adopt them in their training programs.

Conceptually, serious games are related to and somewhat overlap with the following terms: e-Learning, edutainment, game-based learning, and digital game-based learning [73.1]. In 2002, the Woodrow Wilson Center for International Scholars (in Washington, DC) founded the Serious Games Initiative and the term, following the first Serious Games Summit held in 2004, became generally accepted (http://www.seriousgames.org/) and a growing number of scholars began working in this field. Most recently, Sawyer and Smith developed a taxonomy of serious games and made it available on the organization's website (http://www.dmill.com/presentations/serious-games-taxonomy-2008.pdf), and Table 73.1 provides a synthesis of applications in different segments in society.

The illustrative applications of serious games include, but are certainly not limited to, disaster preparedness, health care, military training, and education, the main focus of this chapter (Table 73.2). For a related discussion of the role of automation in education also see Chaps. 44 and 85. *Breslin* et al. [73.3] describe how a game is used to execute and assess the effectiveness of alternative strategies for responding to a disaster. *Kelly* et al. [73.4] introduce *Immune Attack*, a personal computer (PC)-based game, used for learning the rules of the immune system and revealing deeper insights.

Table 73.1 Taxonomy of serious games (courtesy of Sawyer and Smith)

	Games for health	Advergames	Games for training	Games for education	Games for science and research	Production	Games as work
Government and NGO	Public health education and mass casualty response	Political games	Employee training	Inform public	Data collection/ planning	Strategic and policy planning	Public diplomacy, opinion research
Defense	Rehabilitation and wellness	Recruitment and propaganda	Soldier/ support training	School house education	Wargames/ planning	War planning and weapons research	Command and control
Healthcare	Cyber-therapy/ exergaming	Public health policy and social awareness campaigns	Training games for health professionals	Games for patient education and disease management	Visualization and epidemiology	Biotech manufacturing and design	Public health response planning and logistics
Marketing and communications	Advertising treatment	Advertising, marketing with games, product placement	Product use	Product information	Opinion research	Machinima	Opinion research
Education	Inform about diseases/ risks	Social issue games	Train teachers/ train workforce skills	Learning	Computer science and recruitment	P2P learning constructivism documentary?	Teaching distance learning
Corporate	Employee health information and wellness	Customer education and awareness	Employee training	Continuing education and certification	Advertising/ visualization	Strategic planning	Command and control
Industry	Occupational safety	Sales and recruitment	Employee training	Workforce education	Process optimization simulation	Nano/ biotech design	Command and control

America's Army (www.americasarmy.com) was introduced at the 2002 Electronics Entertainment Expo and was, after some initial hesitation, officially embraced and supported by the United States (US) Army as an effective military training simulator [73.5].

In addition to the wide variety of applications, the theoretical underpinnings of learning through gaming were also explored. Although *Gros* [73.6] has some reservations about the current status of research in the educational use of computers (specifically, he cautions that research in this area is still disjointed), he and others also point to some common understanding and principles of learning. First, there are publications showing the advantageous effects of computer games. *Greenfield* [73.7, p. 29] reported that "more skilled video game players had better developed attentional skills

Table 73.2 Serious game types and application examples

Serious game types	Application examples
Game-based education	Game-based learning, edutainment, learning games
Game-based production	Game-based authoring, machine behaviors
Game-based simulation	Game-based simulator, simulation games
Game-based messaging	Game-based advertisement, game-based marketing, advergaming
Game-based training	Game-based trainer
Game-based interface	Game-like interface, game-based graphical user interface (GUI)

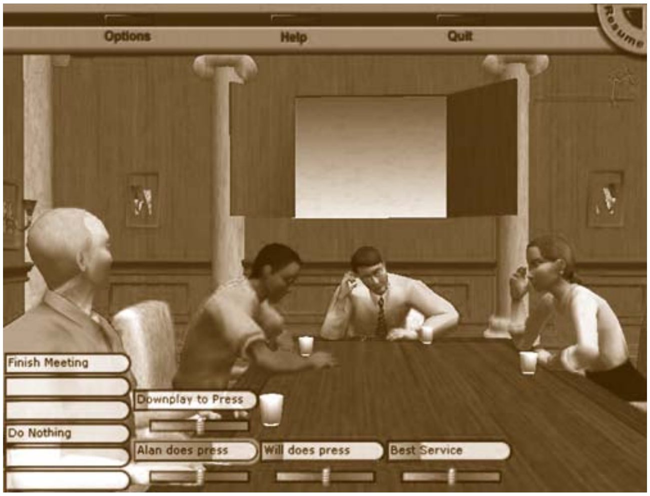

Fig. 73.1 Leadership development to assess critical reasoning using a virtual environment (courtesy of SimuLearn)

than less skilled players." *Backlund* et al. [73.8] wrote about the positive impact that playing computer games had on traffic school students' driving behavior. *Koepp* et al. [73.9] showed that playing video games stimulates substantial dopamine release and that gamers' performance was related to the amount of dopamine present. Considering that dopamine is a chemical precursor to the memory storage event, it can be argued, they write, that video games are able to chemically *prime* the brain for learning. Furthermore, they write (p. 34) that "Beyond science and engineering games, further evidence suggests that games teach not only facts but detailed reasoning applicable to life's many challenges" (Fig. 73.1).

Mayo [73.10, pp. 32–34] listed seven characteristics that enable video games to address the deficiencies of education, specifically the shortcomings of big lecture formats typically used at universities.

1. Massive reach of players/participants.
2. Experiential learning (*If you do it, you learn it*). In games, players must navigate game scenarios and make decisions with consequences.
3. Inquiry-based learning (*What happens when I do this?*). This is the dominant philosophy in science and is also a natural mode for many video games that support freeform exploration, discovery, and experimentation.
4. Self-efficacy (*If you believe you can do it, you'll try longer/harder, and you'll succeed more often than you would otherwise*). In games, points, levels or magic swords are awarded at positive decision points, encouraging players to keep going.
5. Goal setting (*You learn more if you are working toward a well-defined goal*). All games have goals, a key distinction between games and simulations.
6. Cooperation (team learning). Studies of classroom techniques show that cooperative learning results in about a 50% improvement over either solo or competitive learning. Some types of games (such as massive multiplayer online games) are intrinsically structured as a team effort toward a common goal.
7. Continuous feedback and tailored instruction.

Corti [73.11] coined the term *immersive learning simulation* (ILS) and pointed out that many corporate learning professionals and suppliers of ILS are not aware of what is needed to create a *truly effective and appropriate learning solution*. His call is supported by *Zyda* [73.12] who writes about the reasons supporting the need to *deploy immersive storytelling in service to society in the interactive realm*. *Shaffer* et al. [73.13, p. 7] argue that

> *Games are powerful contexts for learning because they make it possible to create virtual worlds, and because acting in such worlds makes it possible to develop the situated understandings, effective social practices, powerful identity, shared values, and ways of thinking of important communities of practice.*

An example of such a virtual world is presented in the sequence of screenshots in Fig. 73.2.

Writing about computer-supported collaborative learning (CSCL), *Salomon* et al. [73.14] used the term *cognitive residue* to refer to a byproduct effect of learners interaction with media [73.15]. By cognitive residue, they meant [73.15, p. 3 and p. 6]

> *subsequent changes in mastery of knowledge, skill or depth of understanding away from the computer [...] higher order thinking skills that are either activated during an activity with an intellectual tool or are explicitly modeled by it can develop and can be transferred to other dissimilar, or at least similar situations.*

These cognitive effects are *effects with technology obtained during intellectual partnership with it, and effects of it in terms of the transferable cognitive residue that this partnership leaves behind in the form of better mastery of skills and strategies*.

It has long been confirmed that learning and doing are tightly linked, as learning typically involves activities as well [73.16]. Many professionals, including current and would-be business managers, are action oriented; they learn to do something that later is to improve business operations. *Schon* [73.17] called the link between knowing and doing a reflective practice.

Professional societies (e.g., for doctors, lawyers, managers) develop supervised settings, residencies for doctors or moot courts for lawyers, where a learner can develop his/her skills by trying a course of action and then reflecting on the results together with his peers and mentors. During this course of action, learners develop epistemic frames of knowledge that are [73.16]:

> *the conventions of participation that individuals internalize when they become acculturated. The reproductive practices of the community are the means by which new members develop that epistemic frame.*

There is a clear message here: learning does not happen in a vacuum; *communities of practice* or *affiliation groups* provide elements of the good learning that include goals, interpretations, practice, explanations,

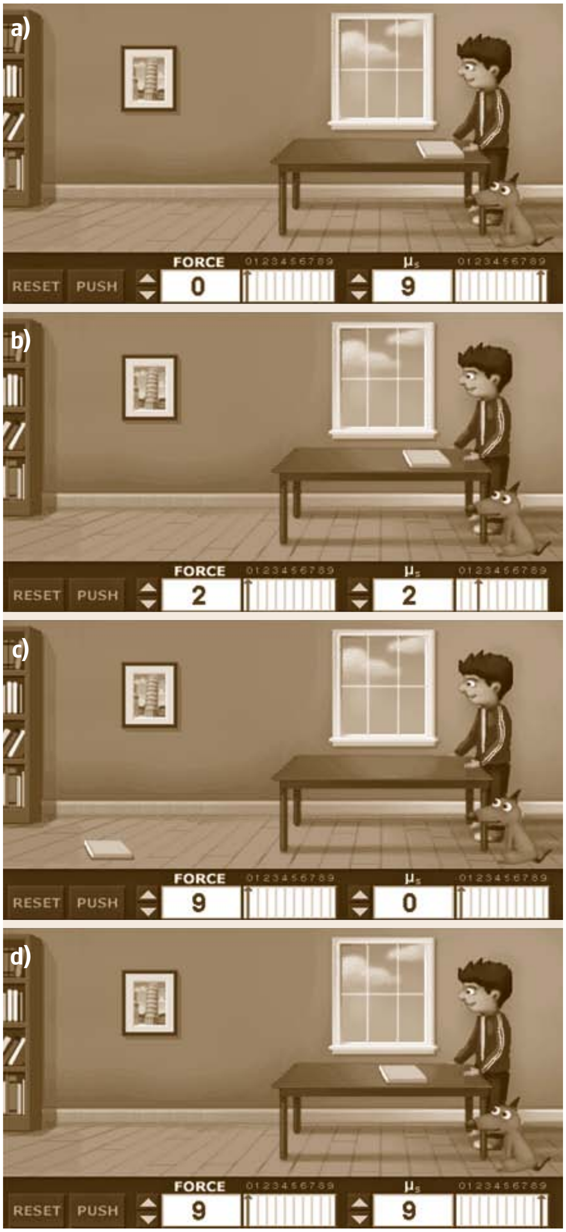

Fig. 73.2a–d The friction explorer allows users to see how a sliding object behaves when the force applied to push it and the coefficient of friction are modified. **(a)** With an applied force of 0 and coefficient of friction of 9, the object does not move; **(b)** with an applied force of 2 and a coefficient of friction of 2 the object barely moves; **(c)** with an applied force of 9 and a coefficient of 0 the object slides off the table; **(d)** with an applied force of 9 and a coefficient of friction of 9 the object moves about one-third of the width of the table (courtesy of Schlumberger Excellence in Educational Development (SEED) http://www.seed.slb.com/en/index.htm) ◀

debriefing, and feedback [73.18]. Serious games represent a clear opportunity to create communities of practice for business professionals.

In all settings or contexts, learning is about content acquisition while games typically focus on experience [73.19]. In other words, there is content (facts, principles, information, skills) that has to be learned. *Gee* [73.18] argues that indirect teaching of content (that is, teaching content via *something else*) is superior to the traditional approach used by schools, which teach content directly. Serious games can be that *something else* that helps in content acquisition by providing a variety of authentic learning experiences that mimic those of professional societies.

New results in learning theory [73.20, 21] show that people primarily think and learn through experiences they have had, assuming that these experiences meet certain conditions. *Gee* [73.22] summarized these five conditions as follows:

1. Experiences are most useful for future problem solving if they are structured by specific goals
2. For best learning, experiences must be interpreted by extracting the lessons learned
3. Learning is enhanced if immediate feedback is provided so that the learners can recognize and evaluate their errors
4. Learners need ample new opportunities to apply and reapply their previous experiences
5. Learners need to learn from interpreted experiences and explanations of other people, both peers and experts.

Gee's *situated learning matrix* [73.18, 22] refers to the linkage between content and identity. Content is given in the context of a goal-driven problem space. Learners move through similar problems representing various contexts and learn to interpret and generalize their experiences in these contexts. In video games, for example, players can get lots of practice at a given level and can then apply what they have learned in less familiar situations (across levels, for example). Through offering learning in varied contexts, the problem of context-specific learning is solved; for example, learning through a case study may leave the learner with knowledge that is specific to the given case but cannot easily be generalized to other settings. On the other end of the spectrum, learning out of context, focusing on principles only, for example, may give learners knowledge that cannot be applied.

Learning, in Gee's view, moves from identity to goals and norms, to tools and technologies, and only then to content. Identity has been linked to two characteristics that enhance learning. First, the ability of the players to have microcontrol over some elements of the game extends and creates an, as *Gee* [73.22] wrote, "embodied empathy for a complex system." The second characteristic is the learner's motivation for and ownership over the successful outcome of the game. The often quoted saying is that *success is based on experience and experience comes from failures*. A lot can be learned from a failed business or from not reaching the next level in a game. If the players are motivated to take risks, try out new ideas, and eventually, learn from the experiences, then the game has a good design.

73.2 Application Examples

Two illustrative examples of serious games are introduced and discussed in this section:

- Management Enterprise Resource Planning (*MERP*) – a dynamic, real-time-based online simulation aimed at strategy execution
- *L'Oreal e-Strat* – an online strategic business market competition game aimed at exploring various strategies by teams of managers who compete in the same market.

73.2.1 MERP

MERP was developed to facilitate learning by offering a variety of managerial contexts in which good practices can be discovered and practised (for details, see http://www.mbe-simulations.com).

Unlike the usual static, written case studies, the dynamic case study scenarios (DCSS) by MBE Simulations offer a live business environment with computerized scenarios that the students must manage and thereby control the destiny of their own business operations. Students participate in a virtual organization that is made real and dynamic as minute-by-minute business events and conditions unfold. Students must respond to and make complex managerial decisions in real-time based on the big picture view. While traditional strategic business games deal with results on a periodic basis (i. e., monthly, quarterly or yearly), the MERP experience involves real-time execution of strategies and the results are shown by key performance indicators (KPI).

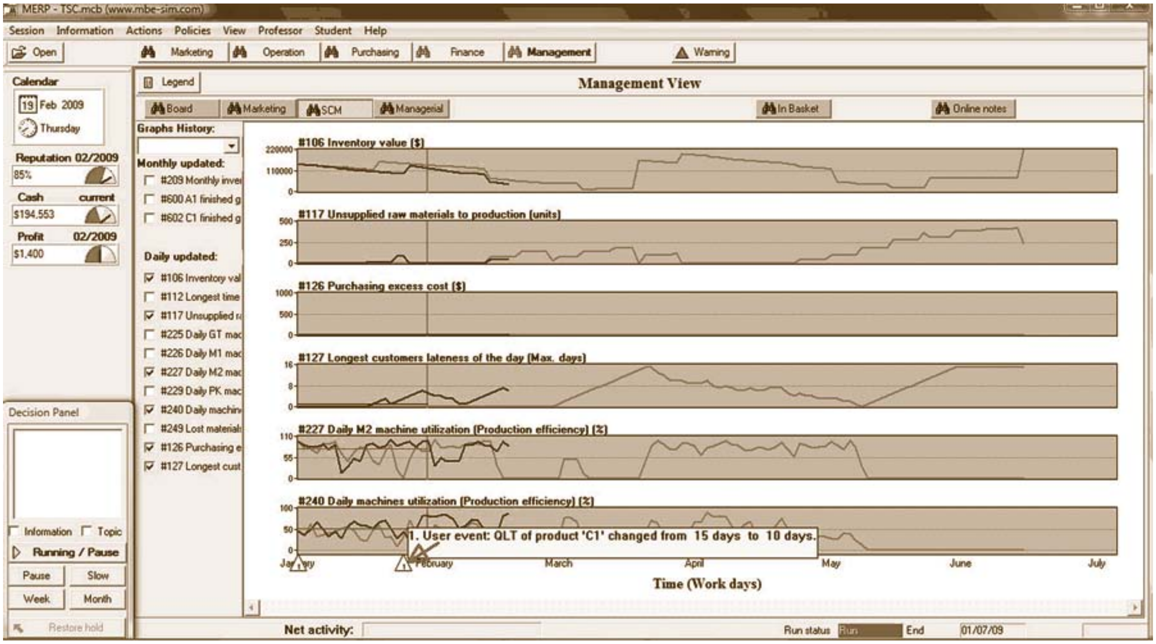
MERP consists of a whole suite of scenarios that cover practices at various levels of complexity and scope. Focusing on individual departments (such as production, purchasing, and others in a production environment), as well as different industrial business processes (make-to-stock versus make-to-order), customer orders and client contracts fluctuate, allowing the use of different management models and inventory purchasing replenishment methods [e.g., the materials resources planning (MRP) mechanism or order level inventory policies]. Students can integrate theory into practice while they learn to test, retest, think, and rethink constantly in various real-life, dynamic situations.

Since 2001, MERP has been used both in traditional and online settings to teach operations and supply-chain management courses for MBAs. These courses involved about 500 students at the Stuttgart Institute of Management and Technology (Stuttgart, Germany), the Kelley School of Business (Kelley Direct Online MBA Program at Indiana University, USA), the CEU Business School (Budapest, Hungary) and the Corvinus School of Management (Budapest, Hungary). Typically, about 30–35% of the total points were assigned to MERP-related work. The simulation software covers the full supply chain of fictitious companies. Generally, students have to work with three scenarios that differ in customer segmentation (small individual customers and/or clients with long-term contracts), product routings (flow shops and job shops), level of variability or randomness, and number of suppliers and final products. Teams of students have to manage these fictitious companies and make a variety of interrelated, complex decisions, so the simulation serves as an integrating theme.

One of the first decisions is to choose the key performance indicators (KPI) from the many options available for monitoring the progress of the enterprise (Fig. 73.3). The screen, in addition to current measurements, also shows a benchmark: results without any intervention (the light grey line).

Managerial success is measured both by numerical results (profit, cash on hand, and reputation level) and by the actions that the students have taken. The profit earned (the more, the better) is the primary measure of success, while the others serve as qualifiers (at the end of the simulation, students have to have positive cash on hand and minimum 75% reputation). The *quality* of the students' decision-making is also evaluated to avoid successes based on random acts not supported by an analysis.

In evaluating the simulation runs, assuming that all qualifiers are met, different weights can be assigned to



Calendar: 19 Feb 2009 Thursday

End 01/07/09

Fig. 73.3 Simulation: management view

the profit earned and to the quality of decision-making. Figure 73.4 describes the relationship between profit and points for one of the scenarios. For illustration purposes, a locally weighted regression line is shown. The point calculations, however, are based on linear functions as described below.

The profit range is divided into three segments: upper, middle, and bottom. In each segment, a linear function describes the relationship between profit earned and points given. This function is steep in the middle and relatively flat at the tails, so the differentiation among the top/low performers is less than among those who are in the middle. The figure also shows that submissions with the same profit received different point scores; these fluctuations are due to differences in the quality of decision-making scores.

In many ways, the simulation's virtual world mimics real life. First, like in real life, there are multiple factors with which students must interact. There are many potential problems and no prepared solutions to counter these. With the MBE Simulator software, what at first appears to be a very simple scenario raises many complicated interactions that are not as straightforward as the student might think. Students have to understand and get an overview of the whole supply-chain picture, which can be quite an overwhelming experience for most of them.

Also, in MBA programs, there is ever-increasing pressure on getting better grades (and later converting better grades into better jobs), thus increasing the temptation for cheating. As a result, much copying and information exchange goes on between current and past students. With traditional case studies, students can easily obtain the whole discussion to see how it was led and managed. To try to prevent this, professors have to regularly change, revise, and update teaching materials just to prevent cheating. However, the principal problem with cheating, if we put aside the ethical considerations and the added work to prevent it, is that students learn nothing from it.

The simulator offers a solution to this problem by providing an ongoing measurement of how much time each student has spent on the simulator. Furthermore, the professor can recreate the work done by the students and see exactly what path they took and what decisions they made. The students are also required to submit an executive summary that describes their management philosophy, tactics, and decisions. This assignment challenges students to reveal the way in which they managed and why they did so, just like real-life boards of directors are required to do. In class, students are asked why they made each decision. This is completely different from the usual executive summary, where only managerial slogans are used. Here the summary (10–12 pages total) provides real insights into the company, and is a good indicator of the extent to which the students understood the problem.

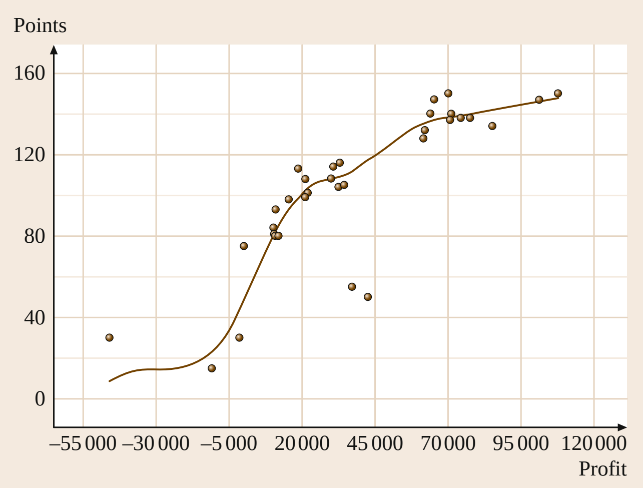

Fig. 73.4 Relationship between profit and points for one of the scenarios. A LOWESS/LOESS locally weighted regression line is shown

In sum, in the simulation most of the cheating-related problems are eliminated, because it takes far more effort to copy someone's notes (and then answer questions during the presentation of the results) than to learn while running the simulator. In addition, the complexity of the scenario allows for more than a single, well-defined solution. Rather, the simulation provides an ongoing search for solutions.

Learning with the simulator is ideal because it can be used to illustrate, for example, inventory modeling embedded in practice. In traditional problems (at the end of textbook chapters), one paragraph describes the problem, which is basically a mathematical problem, and the students simply plug in the numbers and get the answer. In the simulator, you can actually see (through the graphs and through the mechanism itself) the impact of changing a parameter on other parameters (such as changing the order point or order quantity). Other teaching topics that can be illustrated by the simulator are: forecasting, master production scheduling, MRP, bill of material, rough cut capacity planning, purchasing, and choosing suppliers. In short, you can cover every topic included in any operational management course.

MBE Simulations has also developed and customized some virtual worlds for various organizations, including SAP, Amdocs, Kodak, Motorola, Bank Leomi, Biosense (Johnson and Johnson), Lucent, KPMG, Cellcom, Tnuva, Israel Military Industries, and Orbotech.

73.2.2 L'Oreal e-Strat

L'Oreal e-Strat, the second example, is the biggest online game used by universities and corporations. During 6 months (= six decision rounds), which corresponds to 3 years in real time, students in teams of three assume the responsibilities of the chief executive office (CEO) in a virtual cosmetics company. In order to achieve the highest share price index, teams have to make decisions about pricing, production volumes and capacity, logistics, research and development, marketing, advertising, and brand positioning after analyzing data and charts of competitors and the market situation.

The students have to analyze a periodical report after every round which contains information about revenues, gains and losses, production quantity, capacity utilization, market research studies, competitors, brand perceptions, and benchmarking with other competitors. Based on the information in the report, the students have to make decisions in the following areas of the company's value chain: research and development, production planning, brand management, distribution, and corporate social responsibility. The decisions that the students can make are limited by a budget, which is determined by the performance of the last round.

Each area has its own additional, area-specific decisions:

Research and development decisions have an impact on customer satisfaction as well as on customer demand.

In the *production planning* section, by changing policies in terms of pricing, advertising, distribution or even research and development, it is likely that demand for certain products will vary strongly over time. High prices for products or low prices for competing products normally lead to a decrease in demand. In order to satisfy the demand of all customers and in order not to produce products to stock, the management has to forecast market demand and include it into the production planning. If students assume too low a level of production capacity, demand will not be met, which will have a negative impact on the revenues of the company and negatively affect the share price index (SPI).

In the e-Strat world, there are four *distribution channels*. Management has to allocate distribution and trade marketing budget to each retail channel depending on the shopping habits of the target group.

Among other considerations, the e-Strat structure includes *corporate social responsibility*. Management can decide if the company wants to invest in CSR activities (e.g., water reduction, career tracking, and kindergartens for employees). These investments will lead to better company reputation and can have a positive impact on the SPI.

E-Strat is a complex business simulation that covers all areas of a company's value chain. The game is based on decision rounds that have to be submitted to a central server that evaluates the results. However, although the simulation claims to show all responsibilities of the CEO, there seems to be an emphasis on strategy, marketing, and finance and less on operations.

73.3 Guidelines and Techniques for Serious Games

73.3.1 The Serious Game Solution for e-Learning Characteristics

A serious game realm dictates a *close to reality* replication of a reduced size business that needs to be managed by the trainee. The nature of *learning business by doing* provides a unique characteristic of this virtual world. The MERP and e-Strat solutions described above represent different approaches to serious games.

The comparison in Table 73.3 lists and explains the differences between the two different types of serious games: MERP and strategic business games such as e-Strat.

MERP and e-Strat address *Gee*'s [73.22] five conditions for learning through experience in the following way.

73.3.2 The Virtual World for *Learning by Doing* Characteristics

The main attribute of a serious game for teaching business acumen is its holistic world view aimed at providing the *learning by doing* nature of gaming. As such, the program should be able to simulate complex management situations that call for decision-making based on detailed and transparent analysis of the situation at

Table 73.3 MERP versus strategic business games such as e-Strat

Comparison criteria	Dynamic management workshop (MBE Simulations)	Business games (strategic or finance)
Decision type	*Realistic, daily-based* events that affect the organization's results	Strategic (investments, penentration of a new market, etc.)
Decision making	*Dynamic decision making.* Choosing when and which decision to make in parallel with the evolving KPI status	Mandatory periodical set of decisions (i. e., quarterly)
Competitive nature	Teams are competing based on *actual benchmark results*. Scenarios are stochastic, reflecting turbulent daily business life	Direct competition based on profit or share price index reflected. The dynamic is limited to competition cycles only.
Learning effectiveness	*Reinforced learning*: Repeated runs of the same organization	The game runs once, cannot be repeated
Learning scope	Aimed at improving the learner's effective strategy execution abilities. Managerial and business insights built upon tactical daily experience gained: Cause and effect, system thinking, and accepting and dealing with uncertainty	Focusing on strategic learning

hand. Such a program should incorporate the following approaches to learning and education:

- *A pool of live dynamic case studies.* These are descriptions and scenarios which depict certain management situations which often occur in real life; for example, in the simulated world of MERP and e-Strat, the trainees are given detailed data on the virtual manufacturing organization including: income statement, descriptions and details of the products and their market segmentation, details of the operational system, characteristics of the raw-material suppliers, cash and credit lines available, and various policies and ad hoc decision-making capabilities. A wide variety of organizational settings in marketing, operational, and finance can be described by different scenarios; *for example, a scenario's cover story may read like this*: the company appears to be well managed; it is doing all the *right things*. The order book is full; it has good customer relations in that it delivers on time and is therefore considered to be a reliable vendor. The company has a good management information system which provides detailed and varied management reports. It has an MRP scheduling and order system. It has reliable raw material suppliers. It has the most modern and reliable machinery in its operations division. It has everything, and is doing everything, that a *good* manufacturing business should be doing. However, it is losing money.
- *It should cover a virtual-world presentation* of the entire company and its environment. When the trainee starts the simulated dynamic case study, the trainee should be able to watch his/her strategies unfold. The important point to note with this type of management simulation is that the trainee is in control and can set the rules, i. e., he/she can determine product prices, lead-time commitments made to customers, operational policies, inventory levels, suppliers to buy from, and so forth. In fact, everything that the trainee would normally plan and control in his own business is available for planning and control in the simulation.
- *It should be equipped with modern information technology (IT) managerial solutions.* As today's turbulent businesses are relying heavily on advanced integrated information systems, the trainee should be able to use such enablers in his/her practice. This need dictates a presentation of an integrated information system as well as a set of key performance indicators (KPIs) for each department of the organization. An example of such a KPI presentation is shown in Fig. 73.1. These IT enabler tools present dynamic changes in the company's situation, and trainees should respond to these changes by executing effective strategies.

Table 73.4 Five conditions for learning through experiences

MERP	e-Strat
Each MERP scenario is structured around very specific goals. Some of these goals serve as order qualifiers (a certain level must be reached but going beyond the required level does not provide extra value) and some as order winners (the more, the better).	The game is structured around one goal: winning the contest, mainly by maximizing share price index.
In workshops and lectures, the simulation runs are interpreted and the lessons learned extracted.	In between the various cycles, the results of the previous round are interpreted.
Throughout each scenario, learners can rely on a wide range of key performance indicators (KPIs) to help them recognize and evaluate their errors.	Throughout each cycle run, learners can rely on a wide range of management reports to help them recognize and evaluate their errors.
This game is aimed at improving learners' effective execution rather than strategic decision making. Therefore, the learners have a practically unlimited number of runs in each scenario to apply and reapply their previous experiences.	Focusing on strategic learning, the learners have six decision rounds which correspond to 3 years in real time. The learning is gained upon the progress of their results impacted by competitors' decisions and not only on their own effective execution.
While the simulation is run individually, the learners are assigned to groups where the members' experiences can be shared. Also, independently of group membership, the results of all individual runs are displayed in a *Top 100* list that provides further motivation and feedback.	Learners are grouped into teams of three. The teams have to decide on pricing, production volume and capacity, logistics, research and development, marketing, advertising, and brand positioning after analyzing charts on competitors and the market situation in order to gain the highest share price index.

- *The decision-making nature* of such a solution should mimic that of real life. At any given point in time, a large number of potential decisions are available to the trainee and the challenge is to decide not only on the decision to make but also on the timing of the decision (that is, when to make a decision). This feature distinguishes MERP from traditional business games.
- *It should reflect a complex integrative and dynamic environment*: This realism is enhanced by the program's ability to introduce contingencies, such as the uncertainty of the market, variations in the supply chain, maintenance downtime, and machinery and plant breakdowns, to mention but a few. The impact of these contingencies is coupled with the impact of the strategic decisions already taken, and integrated with the results to date, in exactly the same way as in real life.
- *The program should describe a generic view of a managed environment.* In order to support real insightful learning, a serious game should provide a virtual-world description different from information system solutions readily available from vendors (i. e., packages from SAP, Oracle, etc.). This will lead the trainee into the *content path of learning* rather than focusing on *is it real?* type questions.

73.3.3 Supporting the *Learning by Doing* Characteristics

Serious games for education/training should enable *learning by doing*. This need dictates the following main characteristics:

- *The role of the manager should be realistic.* In the assignment, the trainee should take the role of a manager who has been called in to take over a bankrupt company. He has lots of historical data which can be used to develop strategic plans for improving the situation, as well as to introduce tactical and operational control mechanisms. The game should provide all decisions and presentations needed for carrying out the strategy developed.
- *It should be fully interactive and integrative.* The trainee should be able to stop the simulation whenever he/she feels the need to review the situation and

think. The trainee should be able to change the policies, rules or decisions at any time and watch the effect. The program also allows the trainee to select and simulate a number of special activities, such as *expediting* and *order consolidation*. The game should describe a whole set of *cause and effect* chains for each decision made, allowing the trainee to explore and learn about the interrelations between decisions and their outcomes as well as about their impact on other business entities.

- *Ease of learning.* The game should lead the trainee along a short, relatively simple, path. Learning should be about content rather than about the mechanics of managing the simulation (as often happens with traditional games).
- *It should reinforce learning.* The solution should allow the trainee to repeat the same scenario again and again, trying a different decision path every time. In other words, this sensitivity analysis allows the trainee to learn from his/her own experience.
- *Putting into practice things learned.* The game should guide and steer trainees in the right directions needed for gaining real experience and making them learn through these experiences.
- *Simulate events that are close to reality*. The game should describe events in business and management that are affected by uncertainties; for example, product cost, product price, inventory level, and product demand by customers are all events that are dynamically and randomly changed in the background during simulation sessions. Consequently, these events cause varied and sometimes unexpected situations to which each trainee must react.
- *Provide monitoring and evaluating.* The game should track trainee decisions and operating performance as well as evaluate the decisions taken. MERP, for example, monitors and displays the decisions made by trainees. The consequences of these decisions (e.g., cash flow, inventory levels, and service levels) are continuously shown to group members (running the same assignment), making learning a shared experience. Additionally, a game should provide ways to test the quality of the trainee's decisions and their effectiveness.
- *Team learning and collaboration.* The game should provide built-in platforms for chat and team communication in a networked environment where trainees can interactively communicate with each other to share opinions and experiences about details and aspects of the simulator program in general or about the specific program scenarios.
- *Learning from the previous experience.* The game should allow saving of simulation sessions as run files. These run files should show the history of the simulation sessions and should be replayed later by the trainee and by professor. Session history executable files contain all decisions, whether simulator and/or trainee generated, exactly as in the originally run simulation session, for trainees to review and analyze separately.

73.4 Emerging Trends, Open Challenges

A significant trend in learning is the paradigm shift in the role of trainee (Iverson, in [73.2]), from passive to accountable active participation. Serious games offer a solution to support this trend.

Unlike traditional business learning approaches, like business games based on *one size fits all* solutions, there is a need for tangible, content-specific business education for motivated and engaged trainees. This need calls for more content about the various business skill areas and about industry-specific needs. *Michael* and *Chen* [73.2] listed the required skills as follows: people skills, job-specific skills, organization skills (that is, how to utilize resources effectively, collaborate, and focus on results, etc.), communication skills, and strategy skills aimed at effective execution of strategy needs.

Over time the generational structure of management will change; the younger generation is becoming more and more game-oriented. This new *gamer* generation is more accustomed to calculated risk taking and needs more challenging learning solutions (Beck and Wade, in [73.2]).

Veen and *Vrakking* [73.23] argued that schools of the future will have longer sessions (4 h periods) and interdisciplinary themes rather than subject-specific content. This trend in management learning will present a challenge to provide more collaboration-based serious games that reflect and mimic the holistic realm of a learning subject, and teachers should also be prepared for this new environment [73.24]. *Freitas* [73.25] wrote that training and education, both physically and conceptually, will shift to new opportunities beyond the traditional classroom. Diverse communities with different needs and cultures will present a new challenge for serious games, learners and educators as well [73.26].

The last challenge in serious game learning is the need to assess learning outcomes. Serious games should be able to show that learning has occurred and the extent to which the learning objectives have been achieved [73.2]. This will elevate the characteristics of the learning game to be directed implicitly and explicitly toward learning goals. It will also require the development of assessment tools for serious games.

74. Automation in Sports and Entertainment

Peter Kopacek

A service robot has to be intelligent, mobile, and able to cooperate with other robots and devices. We are on the way towards multirobot systems in which several robots, called multiagent systems (MAS), will act in a cooperative way together a common task. One of the newest application areas of service robots and especially MAS is the field of entertainment, leisure, and hobby. People have more free time, and modern information technologies lead to loneliness of humans (teleworking, telebanking, teleshopping, etc.). Entertainment robots are expected to be one of the real frontiers of the next decade.

In this chapter a short description of such robots will be given, including some application examples. Due to the broad range of possible applications of robots in entertainment, leisure, and hobby, the following classification has been made in order to give this contribution a basic structure: robot construction sets, sports assistants, promotion and public relations, robots in the entertainment industry, personal robots, humanoid robots, and competition robots.

As an example, robot soccer competitions will be described in more detail. Finally an outlook on future development trends will be given.

There are three *starting* points for the development of intelligent robots (Fig. 74.1):

- Conventional stationary robots
- Autonomous guided vehicles (AGVs)
- Walking machines.

Stationary industrial robots equipped with external sensors are used today, e.g., for assembly and disassembly operations, fueling of cars, etc. and were the first *intelligent* robots.

Mobile platforms with external sensors (AGVs) have been commercially available for some years and cover a broad application field. Mobile platforms are the real roots of service robots.

Walking machines or mechanisms have been well known for some decades. Usually they have four to six legs (multiped) and only in some cases two legs (biped) – from the viewpoint of control engineering walking on two legs is a very complex (nonlinear) stability problem. Biped walking machines equipped with external sensors are the basis for *humanoid* robots. Some prototypes of such robots are available today.

To give an idea about further developments, Fig. 74.1 shows possible development trends in robotics. We are now on the way from unintelligent industrial robots via intelligent industrial robots to intelligent mobile – including humanoid – robots to third-generation *advanced* robots able to interact and work symbiotically with us.

Robots in the 21st century will be used in all areas of modern life. The major challenges are:

- To develop robotic systems that can sense and interact usefully with humans
- To design robotic systems able to perform complex tasks with a high degree of autonomy.

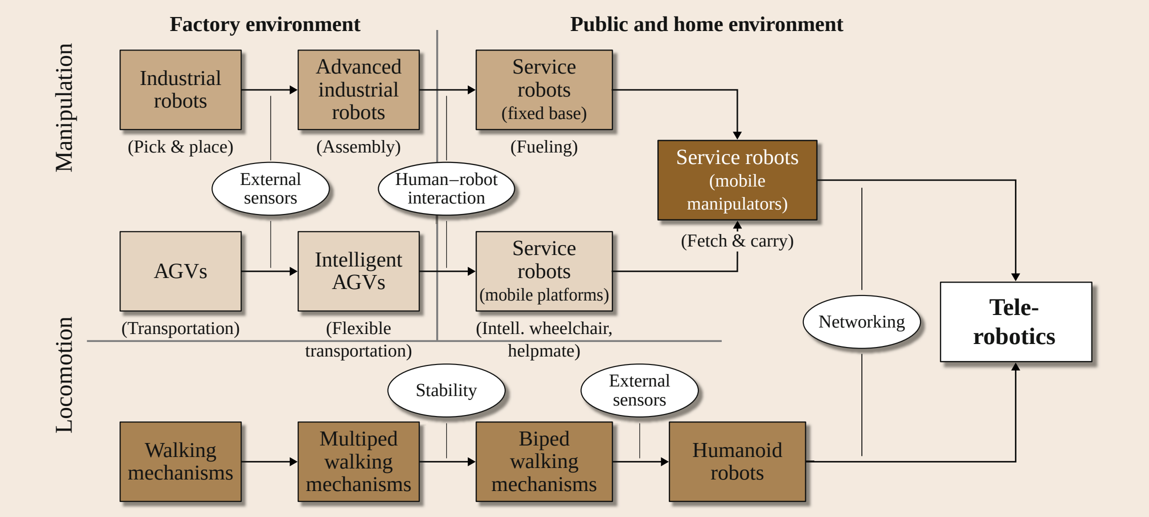

Fig. 74.1 From industrial to service robots (after [74.1])

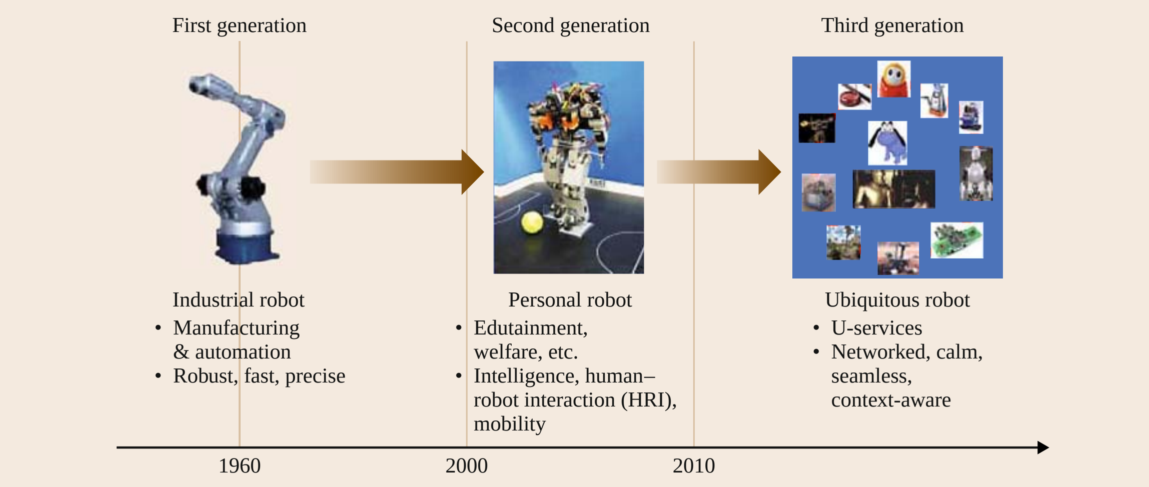
In the same way that mobile phones and laptops have changed our daily lives, robots are poised to become a part of our everyday life. The robot systems of the next decades will thus be human assistants, helping people do what they want to do in a natural ad intuitive manner. These assistants will include: robot coworkers in the workplace, robot assistants for service professionals, robot companions in the home, robot servants and playmates, and robot agents for security and space.

The role of these robots of the future could be improved by embedding them into emerging information technology (IT) environments characterized by a growing spread of ubiquitous computing and communications and of ad hoc networks of sensors forming what has been termed *ambient intelligence.*

Currently available robots are far from this vision of the third generation, being able to understand their environments, their goals, and their own capabilities or to learn from their own experiences.



First generation
Second generation
Third generation
Industrial robot

Fig. 74.2 Development trends in robotics [74.2]

74.1 Robots in Entertainment, Leisure, and Hobby

One of the newest application areas of service robots is in the field of entertainment, leisure, and hobby, because people have more free time, and modern information technologies lead to loneliness of humans (teleworking, telebanking, teleshopping, etc.). We need robots to assist, support, and join humans. The field of *robots in entertainment, leisure, and hobby* was therefore born. The roots of such robots go back more than 20 years ago [74.3, 4]. These robots are usually mobile, intelligent, and cooperative. The idea of making modern automation transparent for a broader public goes back to the middle of the 19th century. One tool for this is playing with automation. First examples were in the field of process automation, e.g., two- and three-tank systems, model railways, model racing cars, etc. At the end of the 19th century and the beginning of the 20th century robots started to attract a broader public. One of the reasons for this is humans' long-time dream of having an intelligent machine looking and acting like us. Therefore robots are currently and will be also in the future *high-tech toys* for playing with automation.

In the past construction sets for stationary, industrial robots served for playing with robots. These model robots were a popular gift not only for children. Approximately 30 years ago the first construction kits for mobile and also humanoid robots appeared on the market. Currently and also in the future the development of entertainment robots is closely connected to the development of real, mobile, intelligent, especially humanoid robots. Most of the *advanced* theories implemented in these real robots are and will be the basis for entertainment and play robots. The main problem can be summarized under the headline *cost-oriented automation* (COA). These robots must be available on the market for a reasonable selling price.

74.1.1 Definitions

First it is certainly important to take a brief look at different definitions of the terms entertainment, leisure, and hobby. Their meanings often overlap, but nevertheless they all mean something different.

Entertainment

This can be defined as: the act or profession of entertaining, i. e., to amuse and interest, especially by public performance and keeping the attention of people watching or listening [74.5]; the act of entertaining, or something diverting or engaging as a public performance, e.g., a (usually light) comic or an adventure novel [74.6].

Leisure

This can be defined as: time when one is free from work or duties of any kind; free time [74.5]; freedom provided by the cessation of activities; especially time free from work or duties [74.6].

Hobby

This can be defined as: an activity which one enjoys doing in one's free time [74.5]; a pursuit outside one's regular occupation, engaged in especially for relaxation [74.6].

74.1.2 Categories

Due to the broad range of possible applications of robots in entertainment, leisure, and hobby, the following classification [74.3] has been made in order to give this chapter its basic structure:

- Robot construction sets
- Sports assistants
- Robots for promotion and public relations
- Robots in entertainment industry
- Personal robots
- Humanoid robots
- Competition robots.

74.1.3 Examples

In the following some *classical* examples, because of the rapid development in this field, are presented and shortly discussed.

Robot Construction Sets

These construction sets often stem from *conventional* technical construction sets that have been upgraded using sensor and microcontroller technology, paired with computer interfaces to allow the user to run self-programmed software. They are mainly for *computer enthusiasts* for testing own-developed software on a cheap hardware.

There are two main types of construction kits available:

- Sets where it is possible to construct various robots
- Sets where only one robot can be constructed

Within these main categories it is also possible to choose from a wide variety of different kits; prices range from under US$ 100 to several hundred US dollars.

The well-known system in the first category is Lego Mindstorms [74.7]. Based on the products of this company, the construction set allows a great variety of possible assemblies due to its modular structure. The only limit is the fantasy of the constructor. The system consists is of a specially developed microcomputer (the heart of Lego Mindstorms), software, 717 elements (bricks, connectors, wheels, and gears), 2 motors, 2 touch sensors, 1 light sensor, and an infrared transmitter for sending programs to the robots.

Mobile Robots is a construction set for sensor-guided robots. The included robot–personal computer (PC) interface allows one to write ones own command routines on the computer and load them into the robot's memory. So the robot can act independently and without any attached cables. Possible constructions are capable of detecting edges and stopping before falling down, are aware of obstacles, and can follow light sources or track plotted lines. As it is a totally flexible system, own creations are possible and appreciated.

Representatives of the second category are robots from a company offering a wide variety of construction kits, but all of them designed for building one robot only. Various models of robotic arms, bipeds, quadrapods, hexapods, polypods, carpet rovers, four-wheel-drive (4-WD) rovers, and sumo robots are available.

Sports Assistants

The robots introduced into this field are systems well equipped with high-tech sensors that assist humans in their favorite sport by performing routine tasks usually annoying such as collecting tennis balls or carrying golf clubs.

Tennis Ball Collector: Jeeves. Developed by a freelance designer in cooperation with a university, this robot collects tennis balls by driving towards them when detected by the onboard charge-coupled device (CCD) camera, and bringing them into a basket in the rear using a rotating brush. Ultrasound distance sensors avoid collisions with obstacles on the court while the robot generates a map of the environment based on its sensor data and stores this information for further use, thus enabling *Jeeves* to sweep an already known court effectively. Path planning is done by a sophisticated computer system running on an off-board workstation that is connected via a radio link.

Golf Caddy: InteleCaddy. This robot replaces a human caddy in a mass sport application where many golfers are not willing to pay for a caddy, currently being installed at golf courses all over the world. The InteleCaddy is a computer-controlled, electrically powered golf caddie robot that navigates around the golf course with its telecommunication skills and sensors, being connected to the golfer via a small pager-sized coded transmitter. The robot features a digital aerial map of the golf course and is programmed to stay within preset boundaries, thus following the golfer with the bags using geographical positioning system (GPS) and ultrasound sensors for navigation and obstacle avoidance. As a bonus, the computer also supplies the golfer with useful information on the course such as exact distance to predefined positions (greens, bunkers, and tees) on the map.

Robots for Promotion and Public Relations

Robots for promotion and public relations can be divided into the categories of tour guide robots and performance robots, hence having very different tasks.

Tour guide robots give information to people while interacting with them, thus attracting and entertaining prospective visitors as well. Performance robots are for performances in public places or at events, mostly with robot systems rented by specialized companies.

Tour Guide Robots. A tour guide robot has to be able to move around autonomously in the environment. It has to acquire the attention of visitors and interact with them efficiently in order to fulfil its main goal: give the visitors a predefined tour. These robots were designed to conduct guided tours in public places such as museums

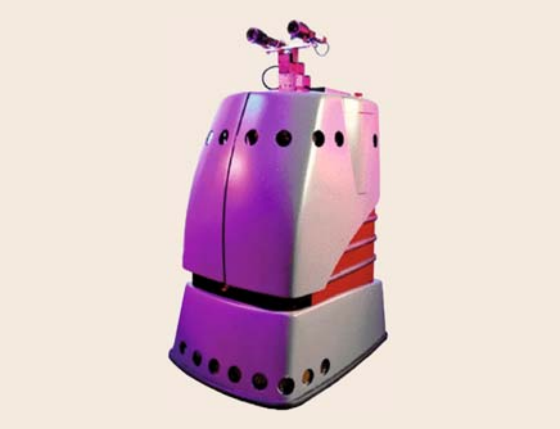

Fig. 74.3 Museum tour guide *Minerva*

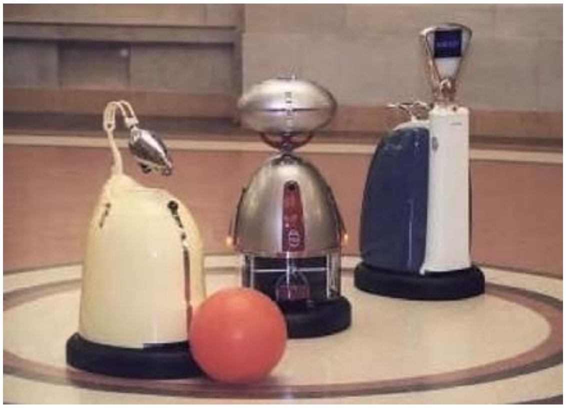

Fig. 74.4 Museum tour guide *Twiddling, Inciting, Instructive*

while managing autonomous sensor-based navigation as well as avoidance of collisions in a densely populated area of unpredictable moving visitors.

The tasks of a tour guide robot are:

- Traveling from one exhibit to the next during the course of the tour
- Attracting visitors to participate in a new tour between tours
- Engaging people's interest and maintaining their attention while describing a specific exhibit.

Furthermore, they are equipped with social interaction features, which range from rather simple voice output (*RHINO*) [74.10] to a combination of voice, facial expressions, and a model to express feelings as well (*Minerva*), giving the robot a *human touch*. The navigation system of both units is based on real-time processing of sensor data to generate a map of the environment.

Minerva [74.11] was developed in 1998 by Carnegie Mellon University and the University of Bonn and is working in the Smithsonian's National Museum of American History, USA.

These robots, developed by Fraunhofer IPA, Stuttgart, have been in use in the Museum für Kommunikation in Berlin, Germany since 2000.

Performance Robots. The main task of performance robots is to entertain people, often using low-tech applications with a few sensors, limited computing power, and no capabilities to act autonomously. Systems such as *Robosaurus* or *Boxerjocks* can be rented for large public events to attract visitors and thus increase the revenue of the renter.

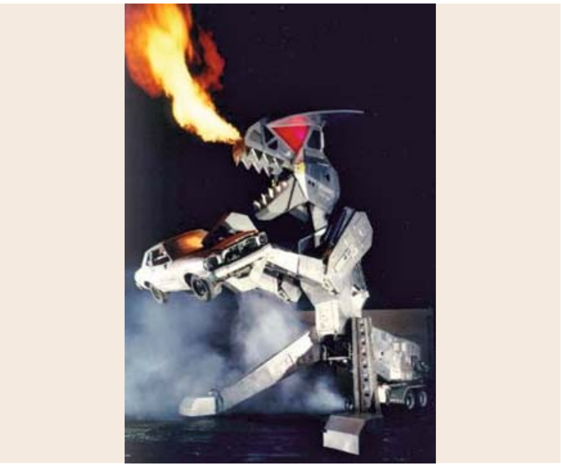

Fig. 74.5 *Megasaurus* [74.8]

Due to the existence of a large number of companies renting or distributing performance robots, just a few applications have been included in order to give a short survey of how broad the range of entertainment robots or animatronic systems is in this field.

Megasaurus and Transaurus are modeled after a *Tyrannosaurus rex* and have hydraulically activated arms, grasping claws, and jaws, as well as flame throwers set up in the head to give the effect of breathing fire from the mouth. They both fold up into a vehicle based on a tank and when the robots perform they initially appear as a box on tracks decorated as either a military vehicle (Megasaurus) or a dinosaur (Transaurus). Each robot is roughly 30 feet tall at maximum extension. They are used primarily to destroy cars by *eating* them (ripping them apart with the claws and jaws) at motor sport events, especially monster truck competitions.

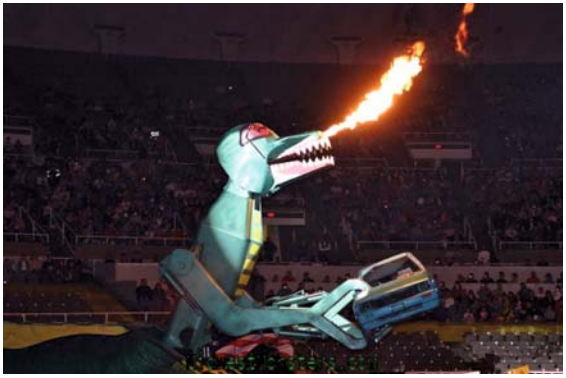

Fig. 74.6 *Transaurus* [74.9]

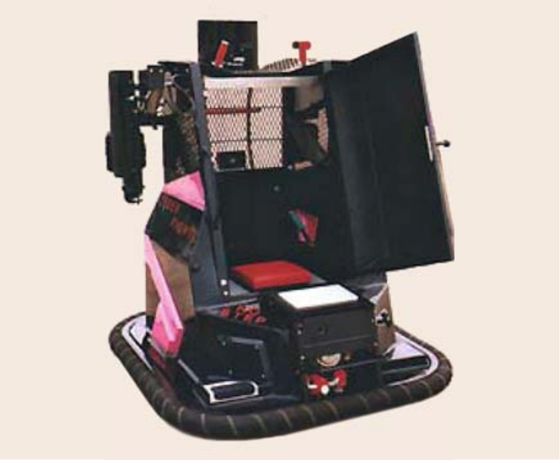

Fig. 74.7 Boxer Jack [74.12]

Boxer Jacks Robotic Boxing is an animatronics system that serves as an attraction in amusement parks or other places where large crowds of people can be found, such as shopping centers. The application system is fairly straightforward: Two of these robots are located within a certain area where they can move around freely. Each of the systems is controlled by a human, who tries to punch the other's robot. Technical features include:

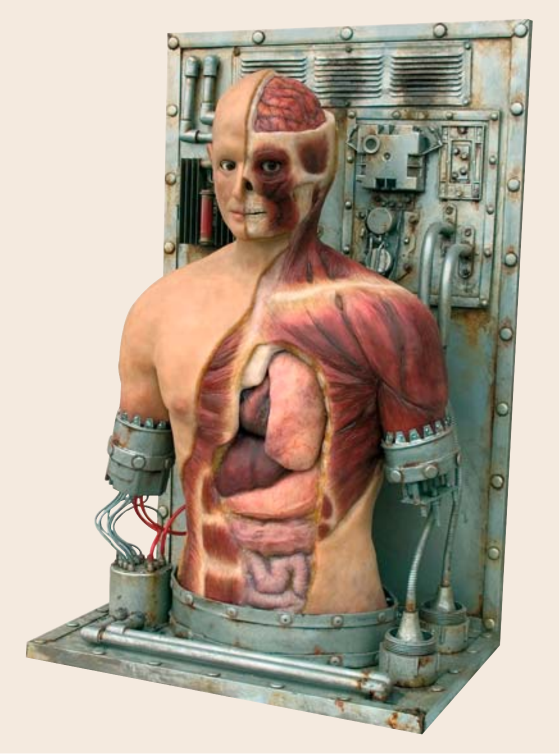

Fig. 74.8 Jekyll and Hyde animatronic (courtesy of Life Formations [74.12])

- Construction – Tubular steel network with a rigid steel mesh surrounding the rider's upper body, providing ample safety and visibility
- Drive – Dependable Honda gasoline engine powers the hydropneumatic system for mobility and arm punching articulations
- Body – Hand-laid fiberglass with choice of color scheme; quality urethane enamel finishes used
- Seating – Designed so that riders aged 8 years through to adults can operate a Boxerjack easily
- Impact areas – Use of heavy rubber on all contact areas, bumper, gloves, and arms cushion all shock loadings during the match
- Electrical – 12 V direct-current (DC) battery system use for arm switching, scoreboard, and head horn.

Robots in the Entertainment Industry

Robot applications in the film industry are often spectacular because of their custom-made special features. In this chapter robots as performing artists, can be found as well.

Film Industry. Starting with *Metropolis* in 1926, dealing with a futuristic city and its mechanized society with humans being replaced by a robot, through *The Day the Earth Stood Still* (1951), *Lost in Space* (1965) to *A Space Odyssey*, robots have frequently been used in films.

One of the most recent examples in movies is *I-robot*; although not based on the the book written by *Asimov*, it was based on the concepts proposed therein, such as the three laws of robotic behavior. It presents a future where robots do all manual labor. One robot is programmed and trained to understand human emotions, and commits murder due to a promise and out of love. The robots take over as they get deeper understanding of the three laws – mankind is destroying itself and has to be protected from self-destruction.

As the entertainment industry was one of the first fields to use service robots, there is a huge variety of applications in theme parks and especially movies, where robotic and animatronic creatures are often combined with animated computer graphics to realize spectacular special effects (Figs. 74.8–74.10).

Another field of robotic applications is in the performing arts, where robots can be found rather seldom, but therefore in mostly amazing performances that partly have a scientific background as well.

Robotic Snake in Anaconda. This lifelike replica of the giant *Anaconda* is a high-tensile-steel robot structure, consisting of individually controlled artificial vertebrae that are driven by hydraulic cylinders. The system is controlled by more than 70 coupled microprocessors with a special control concept that allows the underlying hydraulic system to perform the necessary quick movements of the heavy structure.

Robots in Jurassic Park. The robotic system incorporating the *Tyrannosaurus*, the largest one ever built for use in a movie, is a fiberglass frame construction covered by clay and afterwards coated with a specially painted latex skin. As the robot measured 9 m high and weighed 10 t, it had to be supported by a massive foundation usually used for flight simulators.

Other less spectacular systems such as the replica of a *Triceratops*, featuring remotely controlled motors and a mechanism to imitate breathing movements, were also used in the movie.

Robots as Performing Artists. The robot band introduced here is a pretty low-tech application for entertainment purposes that plays digital music from a computer disk while the animated robotic figures pretend to move to the sound and play their instruments.

Although the *Ullanta Performance Robots* seem at first sight to exist solely for entertainment, these fully autonomous robots are used for research in cooperative robot group behavior and multiagent systems as well, both employed in a dynamic environment. These robots are, within certain boundaries, allowed to *interpret* the script based on their own software.

Personal Robots

Pet Robot: Furby. Being the ancestor of all pet robots, this popular animatronic pet is equipped with a computer chip, various sensors, and a small motor. It responds to its environment in *Furbish*, a nonsense lan-

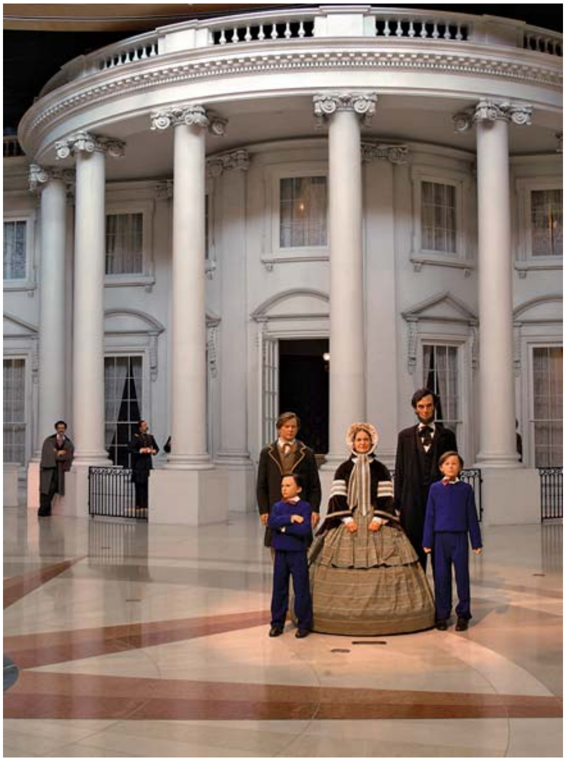

Fig. 74.9 Lincoln library (Springfield, IL) animatronics (courtesy of Life Formations)

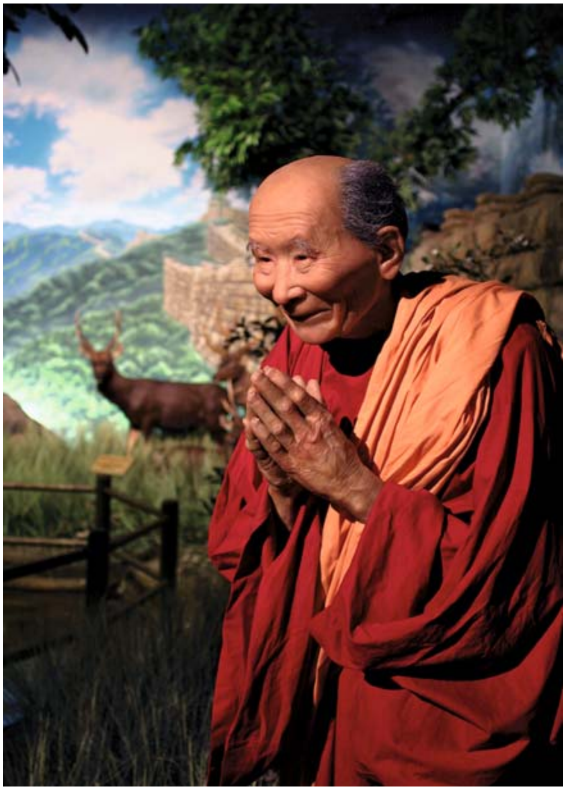

Fig. 74.10 Rolling Hills, Kansas Museum animatronics (courtesy of Life Formations)

guage, and is able to communicate with other *Furbies* via infrared signals.

Personal Robot: R100. This prototype mobile personal robot uses a completely new voice-controlled approach, thus providing a more natural, buttonless interface in order to become a *real family member*.

With its visual and voice recognition technology and Internet connectivity, it can be used as a voice message or home security system (besides its function as a personal companion).

Catrobot: Tama. Featuring speech output and recognition, this kitten-like pet robot serves as a companion and information source for senior citizens, while being remotely accessible by health or social workers who thus can take care of the elderly without too much intrusion into their privacy.

Robodog: i-Cybie. Described as "a watered-down version of AIBO with almost the same functions without the finesse" in the press, this infrared-controllable robot dog indeed features many of AIBO's functions at a technically lower level but for a fraction of the price.

Robodog: AIBO. AIBO is an abbreviation for artificial intelligence robot. Because of its reduced instruction set computer (RISC)-processor-powered high-tech system including numerous sensors, a color camera, and 18 motors to move its extremities it is the first entertainment robot that can think, feel, and act by itself. It can walk and play, sit, and stretch like dogs and cats. AIBO's brain contains an emotion model to handle feelings and an instinct model to handle drives. The emotion model covers six feelings: happiness, sadness, anger, surprise, fear, and dislike. The instinct model has four components: love, search, movement, and hunger.

Pet Robot: My Real Baby. This interactive, animated doll features instant, sophisticated, and interactive emotion-like responses and is able to simulate a maturation and speech development process.

Humanoid Robots

Entertainment robots are expected to be one of the real frontiers of the next decade. According to latest estimations millions of such robots will be in use in the coming years. The newest developments are *friendly* robots for humans; for example, elderly people need listening and talking friends. We now have dogs, cats, and human-like robots available for reasonable prices, but not really humanoid robots walking on two legs [74.13]. First examples are described below.

Since 1986 the Japanese Company Honda has developed humanoid robots, P2, P3, and ASIMO (advanced step in innovation mobility). The basic idea is to integrate intelligence and moving capability into a robot for trivial tasks. Over the years the robot has become smaller (from 160 cm for P3 to 120 cm for ASIMO) and lighter (from 130 kg of P3 to 43 kg of ASIMO). The newest development is ASIMO. It can move at up to 1.6 km/h and has 26 degrees of freedom (DOFs). This kind of robot can easily be used in home as wheel-driven robots, because of their ability to move over an uneven surface such as stairs.

Therefore service robots will become a real *partner* of humans in the near future. One dream of the scientists is the *personal* robot. In 5, 10 or 15 years everybody should have at least one such robot. Because the term personal robot is derived from personal computer the prices should be equal. Some new ideas in automation, especially in robotics, are realized very quickly while others disappear.

Honda is trying to build the ASIMO robot to be a partner for people. So far it is merely a study about how to imitate humans' movements and make it able to help people somehow. It is 120 cm high, which is enough to reach most gadgets designed for humans. The latest model, introduced in December 2004, can even run at 3 km/h like a human.

QRIO is Sony's [74.14] next step after the robodog AIBO in entertainment robots. It's a bipedal humanoid robot that is able to:

- Walk on uneven and sloppy surfaces
- Run
- Jump
- Perceive depth through its two CCD cameras
- Create a three-dimensional (3-D) map of its surroundings
- Recognize people from their faces and voices
- Learn
- Connect to the Internet via a wireless home network
- Download and read information it thinks you're interested in
- Sing
- Dance
- Survive a fall unscathed and get back up again by itself.

In order for QRIO (Fig. 74.11) to walk and dance so skillfully, an actuator was needed with the ability to produce varying levels of torque at varying RPM speeds and respond with quickness and agility.

The robot moves with *dynamic walking*. *Static walking* means that the robot keeps its center of gravity within the zone of stability – when the robot is standing on one foot, its center of gravity falls within the sole of that foot, and when it is standing on two feet it falls within a multisided shape created by those two feet – causing it to walk relatively slowly. In *dynamic walking*, on the other hand, the center of gravity is not limited to the zone of stability – in fact it often moves outside of it as the robot walks. People move using *dynamic walking*.

If pushed by someone, QRIO will take a step in the direction in which it was pushed to keep from falling over. When it determines that its actions will not prevent a fall, it instinctively sticks out its arms and assumes an impact position. After a fall, it turns itself face up, and recovers from a variety of positions. It is equipped with a camera and the ability to analyze the images it sees. It detects faces and identifies who they are. Moreover QRIO can determine who is speaking by analyzing the sounds it hears with its built-in microphones.

An example of a reasonable cheap entertainment robot is the humanoid robot of Robonova [74.15]. This robot offers educators, students, and robotic hobbyists a complete robot package. It is a fully customizable and programmable aluminum robot (Fig. 74.12). Sixteen digital servos and joints give complete control of torque, speed, and position. The programming software is simple, so advanced knowledge of programming is not needed. It can walk, run, do flips, cartwheels, and dance. The robot is available as a kit – assembly time approximately 8 h – or preassembled, ready to walk robot. In addition to the typical robot talent of walking until it senses a wall using ultrasound, Robonova can be instructed to do cartwheels, take a bow, and even do one-handed pushups.

The simplest way for programming is with the *catch-and-play* function. With RoboScript or RoboBasic the robot is moved to any position and by mouse click that position is *captured*. The software then links these *captured* positions and, once activated, smoothly transitions the robot's movements through these programmed positions.

For beginners in robot programming two software packages are available. With these the users can create operational subroutines without knowing any programming language at all. The computer screen displays sliders for every individual servo (joint). Moving the sliders changes the position of the servos. Simple movements can then be assembled to produce complex movements simply by clicking the mouse. These movements can then be called up on a graphical user interface.

For more advanced users a programming tool based on the Basic programming language is available. This enables the users to create complex applications de-

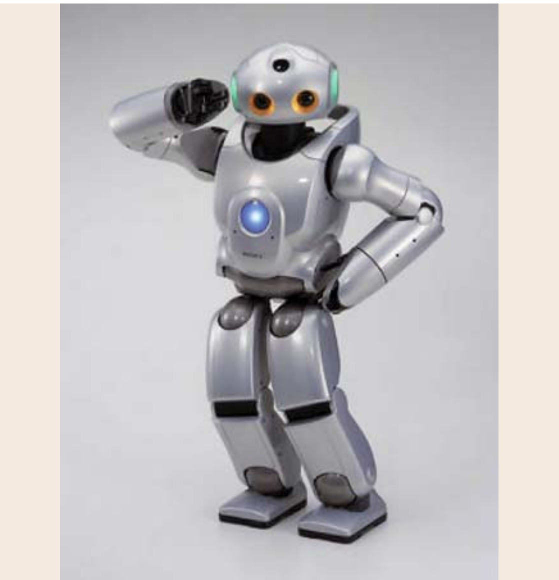

Fig. 74.11 QRIO

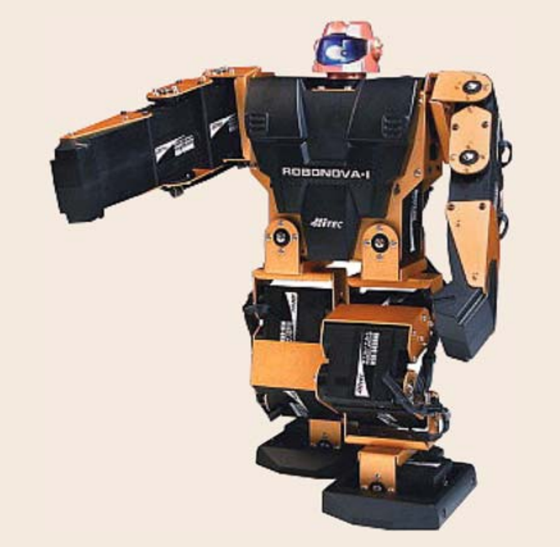

Fig. 74.12 Robonova

signed to accomplish their own individual tasks. The independent development environment includes an editor and compiler. Commands for synchronous servo movements, servo point-to-point movements, and servo motion feedback are also available. The robot can be extended with several accessory modules and items: additional servos and brackets, gyros, acceleration sensors, speech functions, remote control (RC) accessories, and more can also be added as they become available.

The RoboSapien (Fig. 74.13a) is a toy-like robot [74.16] preprogrammed with moves, which can also be controlled by an infrared remote control included with the toy, or by either a personal computer equipped with an infrared transmitter, or an infrared-transmitter-equipped personal digital assistant (PDA). The toy is capable of walking motion without recourse to wheels within its feet. It is also able to grasp objects with either of its hands, and is also able to throw grasped objects with mild force. It has a small loudspeaker unit, which can broadcast several different vocalizations, all of which appear to be recordings of a human male pretending to be a great ape, such as a gorilla.

The toy's remote control unit (Fig. 74.13b) has a total of 21 different buttons. With the help of two shift buttons, a total of 67 different robot-executable commands are accessible.

The remote controller is equipped with a basic level of programmability. Users can string together movement commands to form what the toy's manual describes as either macros or mini-programs, but which are more correctly described as robotic instructions sets. It is also possible to produce a sensor-keyed instruction set.

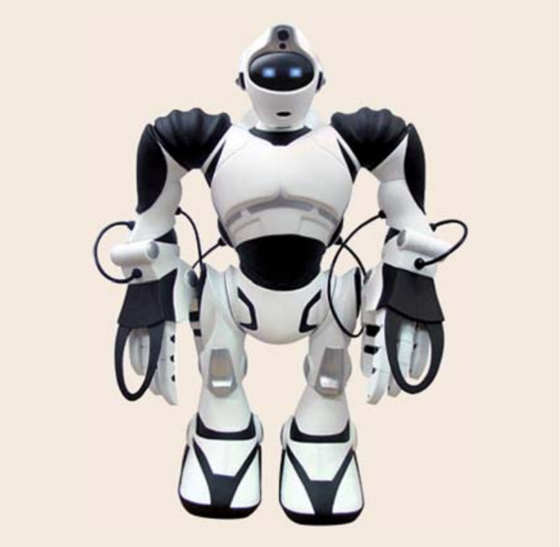

Fig. 74.14 RoboSapien V2

The original robot was developed in the year 2000 and was a brilliant achievement of breakthrough design. It could walk, grasp, and respond – in human-like ways.

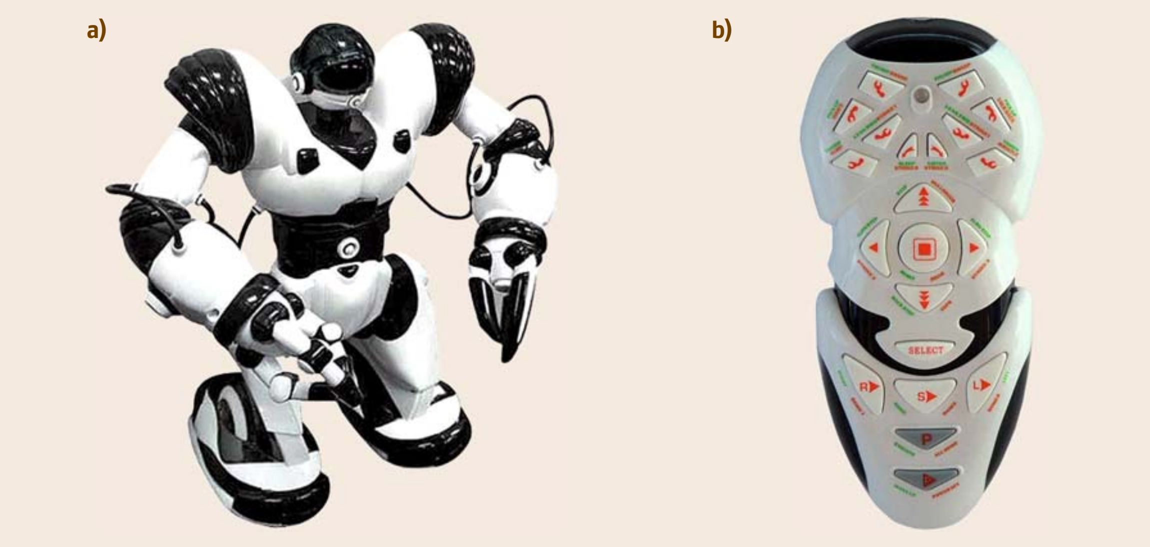

Fig. 74.13 (**a**) RoboSapien, (**b**) remote control

Fig. 74.15 RS Media

The next generation (Fig. 74.14) was released in 2003 and is nearly twice the size of the original robot. Instead of the original caveman grunts the V2 can speak a reasonably large list of prerecorded phrases. It has infrared and basic color recognition sensors, grip sensors in its hands, touch- or contact-activated hand and foot sensors, and sonic sensors. For movement the V2 has an articulated waist, shoulders, and hands, giving it a wide variety of impressive body animations.

The latest model, the RS Media (Fig. 74.15), which was released in October 2006, uses basically the same body as V2, but a different brain based on a Linux kernel. As the name implies, RS Media's focus is on multimedia capabilities, including the ability to record and playback audio, pictures, and video.

Another example of a reasonable cheap entertainment robot is a 12 inch-high robot that can walk, run, and do flips, cartwheels, and dance moves, and that, once programmed, is ready to compete in distinct competitions. This fully articulating humanoid is controlled by a control board, which can operate up to 24 servos and 16 accessory modules with 16 digital servos.

Optional devices will eventually include gyros, acceleration sensors, speech synthesis modules, and operational devices such as Bluetooth controllers and R/C transmitters and receivers. The operation time with a five-cell rechargeable battery pack is approximately 1 h.

The main problem with such robots consists in the preprogrammed movements and that it is not easy to add some software modules.

Competition Robots

A very popular group of entertainment robots are those for competitions. A robot competition is an event where robots have to accomplish a given task. Usually they have to beat other robots in order to be judged the best. Most competitions are for schools but, as time goes by, several professional competitions are arising. There is a wide variety of competitions [74.17] for robots of various types. The following examples describe a few of the higher-profile events.

The idea of a robot competition is not new; they have been held for several years at, for example, the Massachusetts Institute of Technology (MIT) in Boston and Eidgenössische Technische Hochschule (ETH) in Zurich. Having a robot competition in an academic curriculum is highly beneficial, as it gives students open-ended problem spaces, teaches them to work in groups (of two or three persons), and stimulates creativity [74.18].

Classical examples are:

- Robot outdoor tournaments
- Robot soccer
- Ping-pong-playing robots
- Robot wrestling
- Sumo wrestling robots
- Billiard robots.

Table 74.1 gives some examples of robot games.

RoboGames. RoboGames [74.19] (previously ROBOlympics) is an annual robot contest held in San Francisco, California. RoboGames is the world's largest

Table 74.1 Examples of robot games

Beam robot games/olympics		Robofesta official games
Solarroller	High/long jump	Robocup
Photovore	Legged race	Robot grand prix
Aquavore	Innovation machine	All Japan sumo tournament
Rope climbing	Robot-art	All Japan micromouse contest
Robot sumo	Micromouse	
Nanomouse	Aerobot compet.	

open robot competition. They invite the best minds from around the world to compete in over 70 different events. About two-thirds of the robot events are autonomous, while the remaining one-third are remotely operated.

The first goal is to bring builders from combat robotics (mechanical engineering), soccer robotics (computer programming), sumo robotics (sensors), androids (motion control), and art robots (aesthetics) together for exchange experiences. The second goal is to offer recognition to engineers from around the world in varying disciplines with consistent rule sets and low cost or without contestant fees. There are no prerequisites for contests; the event is open to anyone, regardless of age or affiliation. Twenty-eight countries competed with more than 800 robots in 2007.

Competition categories:

- Combat:
  - Categories from 1 to 340 lbs (454 g–154.5 kg)
  - RC and autonomous
- Robot soccer:
  - MiroSot 5:5/11:11 (autonomous)
  - Biped soccer 3:3 (R/C)
  - AIBO soccer 4:4 (autonomous)
- Autonomous humanoid challenges:
  - Basketball
  - Weight lifting
  - Obstacle run
- Autonomous autos
- Sumo
- Bot hockey
- R/C humanoid competition
- Tetsujin (exoskeletons)
- Art bots
- Junior league (< 18 years old)
- Open.

DARPA Grand Challenge. The Defense Advance Research Projects Agency (DARPA) Grand Challenge [74.20] is a prize competition for driverless cars, sponsored by DARPA, the central research organization of the US Department of Defense. Congress has authorized DARPA to award cash prizes to further DARPA missions to sponsor revolutionary, high-payoff research that bridges the gap between fundamental discoveries and their use for national security.

Fully autonomous vehicles have been an international pursuit for many years and the Grand Challenge was the first long-distance competition for robot cars in the world; the main goal is to make one-third of cars autonomous by 2015.

The first competition of the DARPA Grand Challenge was held in 2004 in the Mojave Desert region of the USA along a 150 mile to just past the California–Nevada border in Primm. None of the robot vehicles finished the route. Carnegie Mellon University's Red Team traveled the farthest distance, completing 11.78 km (7.36 mile) of the course.

All but one of the 23 finalists in the 2005 race surpassed the 11.78 km (7.36 mile) distance completed by the best vehicle in the 2004 race. Five vehicles successfully completed the race.

Vehicles in the 2005 race passed through three narrow tunnels and negotiated more than 100 sharp left and right turns. The race concluded through Beer Bottle Pass, a winding mountain pass with sheer drops on both sides. Although the 2004 course required more elevation gain and some very sharp switchbacks (Daggett Ridge) were required near the beginning of the route, the course had far fewer curves and generally wider roads than the 2005 course.

The third competition of the DARPA Grand Challenge (2007) was named the *Urban Challenge*. The course involved a 96 km (60 mile) urban area course, to be completed in less than 6 h. Rules included obeying all traffic regulations while negotiating with other traffic and obstacles and merging into traffic. While the 2004 and 2005 events were more physically challenging for the vehicles, the robots operated in isolation and did not encounter other vehicles on the course. The Urban Challenge required designers to build vehicles able to obey all traffic laws while they detected and avoided other robots on the course. This is a particular challenge for vehicle software, as vehicles must make *intelligent* decisions in real time based on the actions of other vehicles. In contrast to previous autonomous vehicle efforts that focused on structured situations such as highway driving with little interaction between the vehicles, this competition operated in a more cluttered urban environment and required the cars to perform sophisticated interactions with each other, such as maintaining precedence at a four-way stop intersection. Four teams completed successfully the course.

The cars are usually equipped with laser measurement systems, laser sensors, global positioning systems (GPS), and cameras. The teams employed a variety of different software and hardware combinations for interpreting sensor data, planning, and execution. Some examples included C++ and C# running on Windows hosts with planning involving Bayesian mathematics;

and Mac Minis running Linux because it can run on DC power at relatively low wattage and produce less heat. Examples of the latter included Mac Minis running on Windows and an embedded version of Windows XP.

Annual Fire-Fighting Home Robot Contest. The main challenge of this contest [74.21] is to build an autonomous, computer-controlled robot that can find its way through an arena that represents a model house, find a lit candle that represents a fire in the house, and extinguish the fire in the shortest time. This task simulates the real-world operation of an autonomous robot performing a fire protection function in a real house. The goal of the contest is to make a robot that can operate successfully in the real world, not just in the laboratory. Such a robot must be able to operate successfully where there is uncertainty and imprecision. Therefore, the dimensions and specifications listed in the rules are not exactly what will be encountered at the contest and are provided as general aids. However, the size limits on robots are absolute and are enforced by the judges.

Once turned on, the robot must be autonomous, i. e., self-controlled without any human intervention. Fire-fighting robots are to be computer controlled and not manually controlled devices.

A robot may bump into or touch the walls of the arena as it travels, but it cannot mark, dislodge or damage the walls in doing so. There will not be a penalty for touching a wall, but there is a penalty for moving along the wall while in contact with it. The robot cannot leave anything behind as it travels through the arena. It cannot make any marks on the floor of the arena that aid in navigation as it travels. Any robot that deliberately, in the judges' opinion, damages the contest arena (including the walls) will be disqualified. This does not include any accidental marks or scratches made in moving around.

The robot must, in the opinion of the judges, have found the candle before it attempts to put it out; for example, the robot cannot just flood the arena structure with CO_2, thereby putting the candle out by accident.

Early competitions include the following:

Robot Golf Open. An example of a robot competition is the 1996 robot contest called the Robot Golf Open. The contest arena was a rectangular square of 2 × 2 m, surrounded by a 15 cm high wall. The green was located in the middle of the arena and was a 7 cm high disc with a diameter of about 40 cm. Seven golf balls were randomly placed on the arena. It was the task of the robot to locate the balls, pick them up, and put them in some way into the hole, with two points being given for each ball. One point was given if the ball was only placed on the green. It is emphasized here that the robots performed the task autonomously, i. e., they made decisions as to how to control themselves according to the software running on the onboard computer based on sensory information. Two robots *played golf* against each other for a period of 2 min.

Environmental Control Robot Competition. The latest contest with a vision system, held in the spring of 2001, was called *environmental control*; the robot task was to locate three different kinds of garbage in an arena and bring them to the correct container. The arena was 2 × 2 m and contained *containers* at one side, three for each robot. The garbage was either a bottle, a battery or a pack of newspapers.

Other currently well-known competitions are:

Aerial Robotic Vehicle Competitions. The International Aerial Robotics Competition [74.22] is the longest running aerial robotic event, held annually since 1991. This competition involves fully autonomous flying robots performing tasks that, at the time posed, are undemonstrated anywhere worldwide. The competition is open to universities and has had missions involving ground object capture and transfer, hazardous waste location and identification, disaster scene search and rescue, and remote surveillance of building interiors by fully autonomous robots launched from 3 km. A series of micro air vehicle (MAV) events have been sponsored by various organizations. Typically, these competitions involve capability demonstrations rather than missions, and may or may not involve full autonomy.

Ground Robotic Vehicle Competitions. In addition to the DARPA Grand Challenge [74.23] there is also the *Intelligent Ground Vehicle Competition* (IGVC) for autonomous ground vehicles. The robots must traverse outdoor obstacle courses without any human interaction. This is an international student design competition at university level and has held annual competitions since 1992.

Underwater Robotic Vehicle Competitions. This is a spin-off of the International Aerial Robotics Competition [74.24], and as such, carries through the theme of full autonomy of operation, albeit in a subsurface robotic vehicle. This is, since 1997, a collegiate competition.

International METU Robotics Days. The Middle East Technical University (METU) Robotics Days [74.25] are organized in Ankara, Turkey. There are robot competitions from various categories in which original and creative ideas take their part, while innovation is honored. Participants are always encouraged to share their knowledge. International METU Robotics Days, apart from holding competitions for those who would like to challenge their skilled robots, also host professionals and academics interested in the field of robotics to come together in lectures and workshop studies with younger amateurs, giving them the opportunity to take a closer look at this continuously developing technology.

IEEE Micromouse competition. In the classical Micromouse competitions [74.26], small robots try to solve a maze in the fastest time. Micromouse competitions were held first in Tampere Finland Technical University around 1983–1985.

Botball Educational Robotics. Botball [74.27] is a robotics competition for middle- and high-school students. Organized by the KISS Institute for Practical Robotics, Botball encourages participants to work constructively within their team, building basic communication, problem solving, design, and programming skills. Each team builds one or more (up to four) robots that will autonomously move scoring objects into scoring positions.

Mobile Autonomous Systems Laboratory Competition. The Mobile Autonomous Systems Laboratory [74.28] is one of the few college-level vision-based autonomous robotics competition in the world. Conducted by and for MIT undergraduates, this competition requires multithreaded applications of image processing, robotic movements, and target ball deposition. The robots are run with Debian Linux and run on an independent OrcBoard platform that facilitates sensor-hardware additions and recognition.

Wall-Climbing Competitions. There are two worldwide known events. The Duke Annual Robo-Climb Competition (DARC) [74.29] in the USA and the Climbing and Walking Autonomous Robot (CLAWAR) [74.30] competition in Europe. The task is to create innovative wall-climbing robots that can autonomously ascend vertical surfaces of different materials with obstacles.

AAAI Grand Challenges. The two Association for the Advancement of Artificial Intelligence (AAAI) Grand Challenges [74.31] focus on human–robot interaction, with one being a robot attending and delivering a conference talk, the other being operator-interaction challenges in rescue robotics.

This is only a selection – there are a lot of other robot competitions worldwide, mainly dedicated to BSc students.

As an example, robot soccer will be described in more detail below.

Robot Soccer

The fascinating idea of using small robot cubicles to play soccer was born just a decade ago in Korea and Japan and has since spread all over the world. Yearly championships are even organized in different countries. From the scientific point of view, robot soccer is one of the first applications of a MAS. The players – robots or agents – have to solve a common task, i. e., to win the game.

Robot soccer was introduced to develop intelligent cooperative multirobot (agents) systems (MAS) and to educate the young generation in these difficult scientific and engineering subjects by playing. From the scientific viewpoint the soccer robot is an intelligent autonomous agent which carries out tasks with other agents in a cooperative, coordinated, and communicative way. Generally robot soccer is a good test bed for the development of MAS. Furthermore it is also a good tool for spending leisure time and for education [74.32].

In the future, production systems will become more complex. Several independently working autonomous mobile robots are working together, and therefore conflict situations in certain areas could appear, e.g., where several robots gather at an intersection. In order to avoid conflict situations and delays, and guarantee smooth movement, robots should have the capability to communicate and cooperate in order to coordinate their actions.

Soccer is one of the best known sports worldwide. It is exciting to watch how robots play the game. It is also possible not only to watch the game but also to play the game – human against computer, human against human – using a joystick as well as a keyboard. The big question for common use is the price of the whole system. With the development of electronic devices and peripheries the cost is going down. For the realization of interdisciplinary research, work should be done in areas such as robotics, image processing, sensors, mechatronics, communication, etc.

At the moment there are two robot soccer organizations in the world: the Federation of International Robot-Soccer Associations (FIRA) [74.33] and RoboCup [74.34]. The objects and scope of both organizations are similar. The size, speed, acceleration of the robots, the sizes of the playgrounds, and the numbers of robots playing are different.

RoboCup. RoboCup is an international research and education initiative. Its goal is to foster artificial intelligence and robotics research by providing a standard problem for which a wide range of technologies can be examined and integrated.

The main focus of RoboCup activities is competitive football. The games are important opportunities for researchers to exchange technical information. They also serve as a great opportunity to educate and entertain the public. RoboCup soccer is divided into the following leagues:

Simulation League. Independently moving software players (agents) play soccer on a virtual field inside a computer.

Small-Size Robot League (f-180). Small robots of no more than 18 cm in diameter play soccer with an orange golf ball in teams of up to five robots on a field with size bigger than a ping-pong table.

Middle-Size Robot League (f-2000). Middle-sized robots of no more than 50 cm diameter play soccer in teams of up to four robots with an orange soccer ball on a field the size of 12 × 8 m.

Four-Legged Robot League. Teams of four four-legged entertainment robots (Sony's AIBO) play soccer on a 3 × 5 m field. The robots use wireless networking to communicate with each other and with the game referee. Challenges include vision, self-localization, planning, and multiagent coordination.

Humanoid League. Biped autonomous humanoid robots play in *penalty kick* and *2 versus 2* matches, and *technical challenges*. This league has two subcategories: kid-size and teen-size.

RoboCupRescue. The intention of the RoboCupRescue project is to promote research and development in this significant domain by involving multiagent teamwork coordination, physical robotic agents for search and rescue, information infrastructures, personal digital assistants, standard simulator and decision support systems, evaluation benchmarks for rescue strategies, and robotic systems, which will all be integrated into a comprehensive system in the future.

Federation of International Robot-Soccer Associations (FIRA). Similar to RoboCup there are also different categories in this *Robotsoccer World*.

Micro Robot World Cup Soccer Tournament (MiroSot). A match shall be played by two teams, each consisting of 5 or 11 robots on a dark playground 220 cm × 180 cm for the middle league, 400 cm × 280 cm for the large league, with an orange golf ball (Fig. 74.16). Only three human team members, a *manager*, a *coach*, and a *trainer*, are allowed on the stage. One host computer per team, mainly dedicated to vision processing and other location identification, is used. The size of each robot is limited to 7.5 cm × 7.5 cm × 7.5 cm. The height of the antenna is not considered in deciding a robot's size.

Nano Robot World Cup Soccer Tournament (NaroSot). Similar to MiroSot, but the size of the five robots is limited to 4 cm × 4 cm × 5 cm. They play with an orange ping-pong ball on a playground 130 cm × 90 cm (Fig. 74.17).

Kheperasot. The Kheperasot game is played by two teams, each consisting of one robot player and up two human team members. The robot is fully autonomous with an onboard vision system. The human team members are only allowed to place their robot on the field, start their robot at the beginning of each round at the position indicated by the referee before each round, start

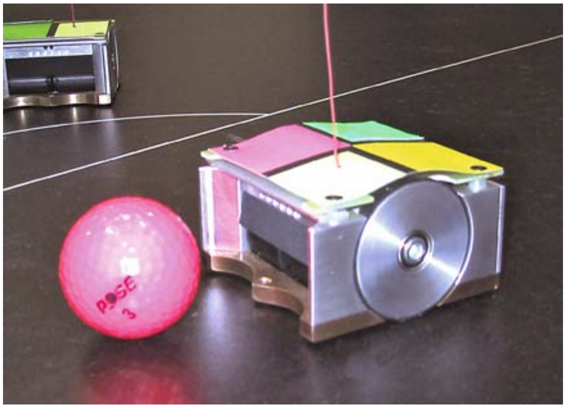

Fig. 74.16 MiroSot robot [74.31]

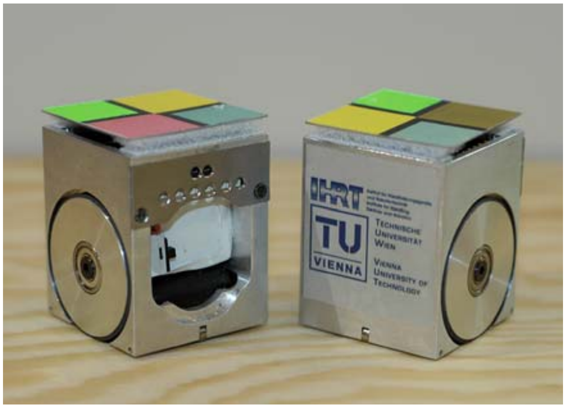

Fig. 74.17 NaroSot robot [74.31]

their robot when indicated by the referee, and remove the robot from the field at the conclusion of the match. They play with a yellow tennis ball on a playground 130 cm × 90 cm.

Humanoid Robot World Cup Soccer Tournament (HuroSotCup). In this competition, the humanoid robot has two legs (biped robot). The game is played using humanoid robots on a playground 340–430 cm × 250–350 cm. The maximum size of the robots is 150 cm, and the maximum weight is 30 kg. The robots have remote or auto control.

RoboSot. A match is played by two teams, each consisting of one to three robots with maximum size 20 cm × 20 cm × (no limit in height) on a playground 260 cm × 220 cm with a yellow with light green tennis ball. Only three human team members, a *manager*, a *coach*, and a *trainer*, are allowed on the stage. The robots can be fully or semiautonomous. In the semiautonomous case, a host computer can be used to process the vision information from the cameras onboard the robots.

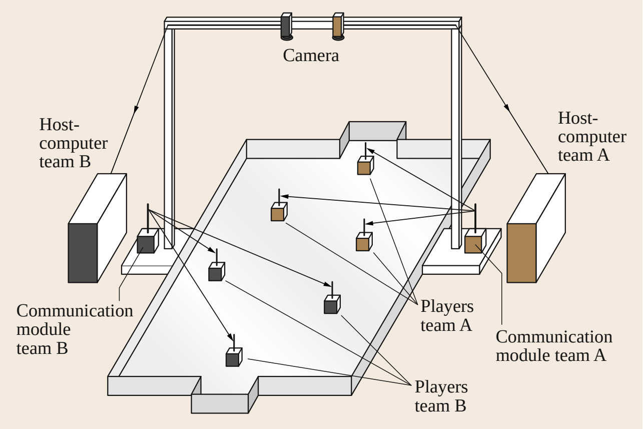

Fig. 74.18 Overall system of robot soccer

Simulation Robot World Cup Soccer Tournament (SimuroSot). SimuroSot consists of a server, which has the soccer game environments (playground, robots, score board, etc.) and two client programs with the game strategies. A 3-D color graphic screen displays the match. Teams can make their own strategies and compete with each other without hardware. The 3-D simulation platform for 5 versus 5 and 11 versus 11 games are available at the FIRA web site [74.33].

MiroSot and NaroSot. The FIRA Mirosot and NaroSot systems work as follow: A camera approximately 2 m over the playground delivers 60 pictures/s to the host computer. With information from color patches on top of the robots, the vision software calculates the position and orientation of the robots and the ball. Using this, the host computer generates motion commands according to the implemented game strategy and sends motion commands wirelessly to the robots.

A soccer robot is an excellent example of mechatronics. Its main parts are wheels, drives, a power source, a microprocessor, and a communication module. All these parts have to be included in a very small volume: a cube 7.5 × 7.5 × 7.5 cm or a cuboid 4.0 × 4.0 × 5.0 cm. The soccer robots of a team (5–11 players) are controlled by the team computer.

The robot itself has a drive mechanism, power supply, electronic parts to control robot behavior, and communication. Mostly digital proportional–integral–differential (PID) controllers are used. The problem is the setting of the controller parameters. Therefore fuzzy control and neural networks are applied to adapt the parameters.

The main problems are the power sources of such robots. Usually batteries are approximately 50% of the weight of the robot and have a lifetime of only 2 h.

Worldwide there are already more than 150 teams competing in regional and world championships.

As pointed out earlier, a soccer robot is an excellent example of multidisciplinarity. For the construction and manufacturing of the body, knowledge of mechanical and, because of the small dimensions, precision engineering is required. Electrical as well as control engineering is necessary for the drives and the power source. The control and communication board of the robot is more or less applied electronics. A microprocessor serves as an internal controller and is also responsible for wireless communication with the host computer. For these tasks and for the software of the host computer fundamental knowledge in computer science is necessary. The software of the host computer includes online image processing, game strategies, control of the team's own players, communication with and between these, and the user interface.

Development of a robot soccer team therefore requires the teamwork of specialists from various disciplines, having different thinking and talking a different language. The project leader has to harmonize such a team and must have at least basic knowledge of all these necessary subjects.

One possibility to go into a broader market is to replace conventional games in amusement parks and restaurants. Therefore, as a first step in this direction, the software had to be adopted to use also a joystick to control each robot player. This offers the following possibilities for playing:

- Humans against humans (both teams controlled by joysticks)
- Humans against computer (only one team controlled by joysticks)
- Computer against computer (state of the art).

In contrast to soccer video games this new technology offers a *real-life* feeling similar to that in a soccer stadium.

A special application is robot dancing. Mirosot robots are programmed for dancing and are judged on criteria such as creativity and costumes. With a user-friendly programming interface a 2 min dance can be created in half a day without any pre knowledge. As an example Fig. 74.20 shows two Mirosot robots from the soccer team of *Vienna University of Technology* dressed in tuxedo and white robe ready for dancing the world-wide well-known Blue Danube Waltz.

Until now the robots are completely unintelligent; they have no sensors and are controlled by the host computer. In the future robots will be more and more intelligent and will be equipped with different sensors (ultrasonic, infrared, laser, etc.). This offers the possibility for robots to adapt the commands of the host computer.

Future developments will be towards humanoid soccer players. A humanoid soccer playing robot has to:

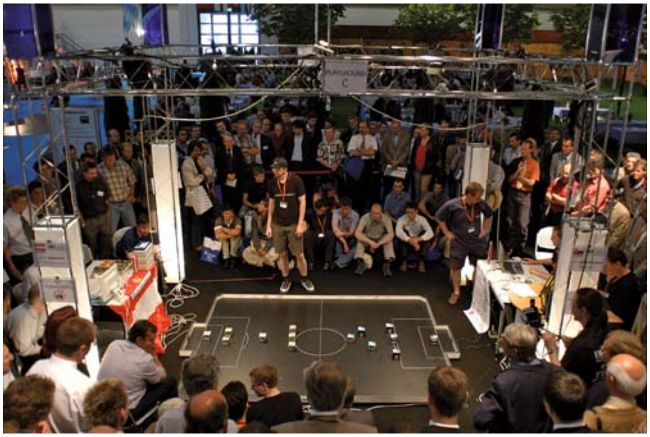

Fig. 74.19 Overall view of robot soccer

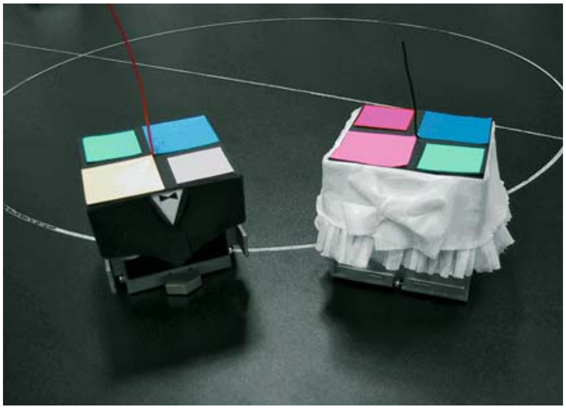

Fig. 74.20 Dancing couple for a Vienna waltz

- Be able to accelerate and slow down as fast as possible
- Keep its balance all the time, even after a crash with another robot
- Localize itself on the field
- Localize the ball
- Localize the opponents
- Make autonomous decisions regarding which actions to take.

As a first step some producers are offering robots with four or six legs at a high price. In some years players with two legs will probably be available – then we can start the first soccer games with humans against robots.

74.2 Market

Consumers showed an astonishingly quick appreciation of the new products in this field, especially of *Furby*, the first animatronic pet marketed on a larger scale, in February 1998. This pet's popularity is on the one hand due to the well-prepared marketing campaign that was organized for its introduction and on the other hand to market mechanisms outside the company's control that made these little creatures a must-have item in practically every child's room.

As this product proved to be nearly perfect for the manufacturer, combining low production costs with extremely high customer demands, many other companies copied the product or designed other robotic pets based on the successful concept in the subsequent years to participate in this expanding market as well.

By far the most famous of these *personal companion robots* is AIBO, which sold out over the Internet within minutes, regardless of the fairly high price. For the second generation, introduced in the market at the end of 2000, a large number will be sold.

It is safe to assume that this market will continue to expand, with newly developed and technically even more refined products entering the market. Thus other companies in this market will have to keep pace and develop further products themselves.

Even in related fields such as robot soccer, robots are likely to find their way to the toy market as soon as these systems can be produced in larger quantities and at a lower price than today.

74.3 Summary and Forecast

Mobile, intelligent robots are now available on the market. The number of these robots in use will dramatically increase in the next year. One of the main application areas will be the field of *entertainment, leisure, and hobby* and robot competitions.

Well-known scientists engaged in robotic research, and who dare to make forecasts not only for the immediate future of service robotics but for the more distant future, also believe that the evolution of service robots will basically happen in several stages, being closely linked to progress in computer technology.

The semiconductor market has seen a series of market-driving waves, from the analog wave to the first digital wave, in which the PC was central, to the second digital wave, in which the digital consumer and network were central. After these waves, scientists expect a robotics wave to occur. So the personal robot market will become more important than the PC market. An estimation of one scientist is that a humanoid robot-soccer team will win against the world champions by 2050.

We are talking about entertainment robots in general, beyond QRIO. It would be desirable to develop is a robot companion for human beings. For instance, a robot can hold things in its memory indefinitely. The hardware might break down over the course of many years, but by taking the memory stick and putting it into a new robot, you could transfer those memories to it. In so doing, one can share with it a short time's worth of memories and knowledge and visions. In some ways, a robot could be the ultimate companion. Yet another idea would be a robot that listens to you. The basis for this is the active listening method of counseling, wherein the counselor gives no information but simply listens. A robot can do that too. A robot can listen to complaints, share information, and be a counselor anytime, day or night.

Therefore we will probably see the following generations:

First Companion Robot Generation – 2010

Mobile, human-sized universal service robots, being as intelligent as a lizard, will be able to perform everyday routine work such as cleaning floors, remove garbage or dust furniture. The required computing power for such a robot would be approximately 5 Mips (5 million instructions per second).

Second Companion Robot Generation – 2020

The subsequent robot generation, also designed to assist humans in their everyday activities, performs janitorial services, or simply entertains them, features an advanced processor capable of computing about 100 000 Mips, thus boosting the intelligence level of the system to that of a mouse. These robots can already be trained using praise and censure.

Third Companion Robot Generation – 2030

With computing power advancing further to 5×10^6 Mips, the robotic system reaches the intellect of a monkey.

Forth Companion Robot Generation – 2040

Within 40 years from now, the forth generation of service robots should be capable of abstracting and generalizing problems like a human, thus performing not only routine tasks, but tasks that require preparation and planning as well. Therefore the existence of companies that do not employ a single human worker any more, besides their autonomous robots, might be well conceivable. We are looking forward to what will be realized.

Part H

Part H Automation in Medical and Healthcare Systems

Automation in Medical and Healthcare Systems. Part H Most of the automation inventions, innovations and devices in medical and healthcare systems have just emerged in the recent two decades, and many more are moving out of research labs to hospitals and homes. This part explains the exponential penetration and main contributions of automation to the health and medical well being of individuals and societies. First, the scientific and theoretical foundations of control and automation in biological and biomedical systems and mechanisms are explained, and their significant value for useful implementation and application is detailed. Then, specific areas are described and analyzed in: implantable devices; medical robotic solutions and techniques for a range of medical problems and medical interventions; diagnostics and testing procedures and tools, including the emergence of nano-devices; and the significant progress in medical informatics and medical records and instrumentation. Available, proven, and emerging automation techniques and design for better cost savings and quality assurance in healthcare delivery, and elimination of hospital and other medical errors are also addressed in this part.

75. Automatic Control in Systems Biology

Henry Mirsky, Jörg Stelling, Rudiyanto Gunawan, Neda Bagheri, Stephanie R. Taylor, Eric Kwei, Jason E. Shoemaker, Francis J. Doyle III

The reductionist approaches of molecular and cellular biology have produced revolutionary advances in our understanding of biological function and information processing. The difficulty associated with relating molecular components to their systemic function led to the development of systems biology, a relatively new field that aims to establish a bridge between molecular level information and systems level understanding. The novelty of systems biology lies in the emphasis on analyzing complexity in networked biological systems using integrative rather than reductionist approaches. By its very nature, systems biology is a highly interdisciplinary field that requires the effective collaboration of scientists and engineers with different technical backgrounds, and the interdisciplinary training of students to meet the rapidly evolving needs of academia, industry, and government. This chapter summarizes state-of-the-art developments of automatic control in systems biology with substantial theoretical background and illustrative examples.

75.1 Basics

Advances in molecular biology over the past two decades have made it possible to probe experimentally the causal relationships between processes initiated by individual molecules within a cell and their macroscopic phenotypic effects on cells and organisms. A systematic approach for analyzing complexity in biophysical networks was previously untenable owing to the lack of suitable measurements and the limitations imposed in simulating complex mathematical models. Recent studies provide increasingly detailed insights into the underlying networks, circuits, and pathways responsible for the basic functionality and robustness of biological systems and create new and exciting opportunities for the development of quantitative and predictive modeling and simulation tools [75.1]. The discipline of systems biology has emerged in response to the challenges in modeling and understanding complex biological networks [75.2, 3].

75.1.1 Systems Biology

The field of systems biology combines approaches and methods from systems engineering, computational biology, statistics, genomics, molecular biology, biophysics, and other fields [75.5–7] to help create systems-level understanding of complex biological networks. In particular, systems engineering methods are finding unique opportunities in characterizing the rich dynamic behavior exhibited by biological systems. Conversely, the new classes of biological problems are motivating novel developments in theoretical systems approaches. Two characteristics of systems biology are [75.4]: (1) integrative view points towards unraveling complex dynamical systems, and (2) tight iterations between experiments, modeling, and hypothesis generation (Fig. 75.1).

Although the field of systems biology is relatively young, one can already point to early successes in a number of cases. The work of *Arkin* on λ-phage was one of the first detailed analyses of a stochastic gene switch, and showed convincingly that formal stochastic treatment was required to understand the cell fate switch between lysis and lysogeny [75.8]. The analysis of perfect adaptation in chemotaxis is another example where multiple groups adopted a systems perspective, and key insights have been generated [75.9–11]. Notably, the mechanism for perfect adaptation has been elucidated and interpreted in classical control engineering terms: integral feedback [75.11].

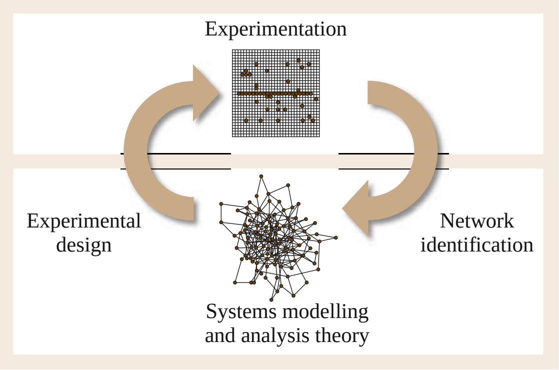

Fig. 75.1 Systems biology iterations. Interactions between experimental analysis and theoretical approaches, and the main tasks for theory at the interfaces (after [75.4])

The approach of model reduction and systematic analysis (including requisite modeling assumptions to yield perfect adaptation) is an excellent example of an effective *systems strategy*. This problem continues to generate new insights, as recent work has shown that disparate organisms have both overlapping and distinctive architectures for chemotaxis [75.11]. Another nice example that has received considerable attention is the gene network underlying circadian rhythms. Models have been proposed [75.12], and formal robustness analysis tools have generated insights on biological design principles [75.13].

A more detailed case study that might be characterized as a success story has also emerged from the work of *Muller* et al. on the JAK-STAT pathway [75.14]. They have shown that modeling-experiment iterations can yield new hypotheses, particularly regarding unobservable components that can be simulated (but never measured). One implication, for the JAK-STAT pathway, involves pharmacological intervention. Current practice focuses on the phosphorylation element of the pathway, but the model shows that a more effective strategy involves the blocking of nuclear export.

75.1.2 Control Research in Systems Biology

Natural control systems are paragons of optimality. Over millennia, these architectures have been honed to achieve automatic, robust regulation of a myriad of processes at the levels of genes, proteins, cells, and entire systems. One of the more challenging opportunities for systems research is unraveling the multiscale, hierarchical control that achieves robust performance in the face of stochastic perturbations. These perturbations arise from both intrinsic sources (e.g., inherent variability in the transcription machinery), and extrinsic sources (e.g., environmental fluctuations). Robustness in key performance variables to particular perturbations has been shown to be achieved at the expense of strong sensitivity (fragility) to other perturbations.

The coexistence of extreme robustness and fragility constitutes one of the most salient features of highly evolved or designed complexity [75.15]. Optimally robust systems are those that balance their robustness to frequent environmental variations with their coexisting sensitivity to rare events. As a result, robustness and sensitivity analysis are key measures in understanding and controlling system performance. Robust performance reflects a relative insensitivity to perturbations; it is the persistence of a system's characteristic behavior under perturbations or conditions of uncertainty. Measuring the robustness of a system determines the behavior (the output or performance) as a function of the input (the disturbance). Formal sensitivity analysis allows the investigation of robustness and fragility properties of mathematical models, yielding local properties with respect to a particular choice of parameter values.

Within the field of systems engineering, control engineering has had a pervasive influence on the discipline of systems biology. For instance, the chemotaxis work [75.11] was a paradigm of collaboration between control engineers (Doyle) and biologists (Simon). Other examples include the robustness analysis of cellular function [75.15] and the unraveling of design principles in circadian rhythm [75.13]. There are many other examples from the control community: for instance, major advances in understanding signal transduction [75.16], and the oscillations underlying a positive feedback gene switch [75.17].

75.2 Biophysical Networks

Biophysical networks are remarkably diverse, cover a wide spectrum of scales, and are inevitably characterized by a range of rich behaviors. The term complexity is often invoked in the description of biophysical networks that underlie gene regulation, protein interactions, and metabolic networks in biological organisms. There are categorically two distinct characterizations of complexity: (1) the descriptive or topological notion of a large number of constitutive elements with nontrivial connectivity (described in Sect. 75.3), and (2) the classical notion of behavior associated with the mathematical properties of chaos and bifurcations (described in Sect. 75.4). In both biological and more general contexts, a key implication of complexity is that the underlying system is difficult to understand and verify [75.18]. Simple low-order mathematical models can be constructed that yield chaotic behavior, and, yet, rich complex biophysical networks may be designed to reinforce reliable execution of simple tasks or behaviors [75.19].

Biophysical networks have attracted a great deal of attention at the level of gene regulation, where dozens of input connections may characterize the regulatory domain of a single gene in a eukaryote, as well as the protein level, where literally thousands of interactions have been mapped in so-called protein interactome diagrams that illustrate the potential coupling of pairs of proteins [75.20, 21]. Similar networks also exist at higher levels, including the coupling of individual cells via signaling molecules, the coupling of organs via endocrine signaling, and ultimately the coupling of organisms in ecosystems. To elucidate the mechanisms employed by these networks, biological experimentation and intuition are by themselves insufficient. As noted earlier, the field of systems biology has laid claim to this class of problems, and engineers, biologists, physicists, chemists, mathematicians, and many others have united to embrace these problems with interdisciplinary approaches [75.22]. In this field, investigators characterize dynamics via mathematical models and apply systems theory with the goal of guiding further experimentation to better understand the biological network that gives rise to robust performance [75.22].

75.2.1 Timing and Rhythm: Circadian Rhythm Networks and Oscillatory Processes

Oscillatory processes are omnipresent in nature, comprising the cell cycle, neuron firing, ecological cycles and others; they govern many organisms' behaviors. A well-studied example of a biological oscillator is the circadian rhythm clock. The term circa- (about) diem (day) describes a biological event that repeats approximately every 24 h. Circadian rhythms are observed at all cellular levels since oscillations in enzymes and hormones affect cell function, cell division, and cell growth [75.23]. They serve to impose internal alignments between different biochemical and physiological oscillations. Their ability to anticipate environmental changes enables organisms to organize their physiology and behavior such that they occur at biologically advantageous times during the day [75.23]: visual and mental acuity fluctuate, for instance, affecting complex behaviors.

The mammalian circadian master clock resides in the suprachiasmatic nucleus (SCN), located in the

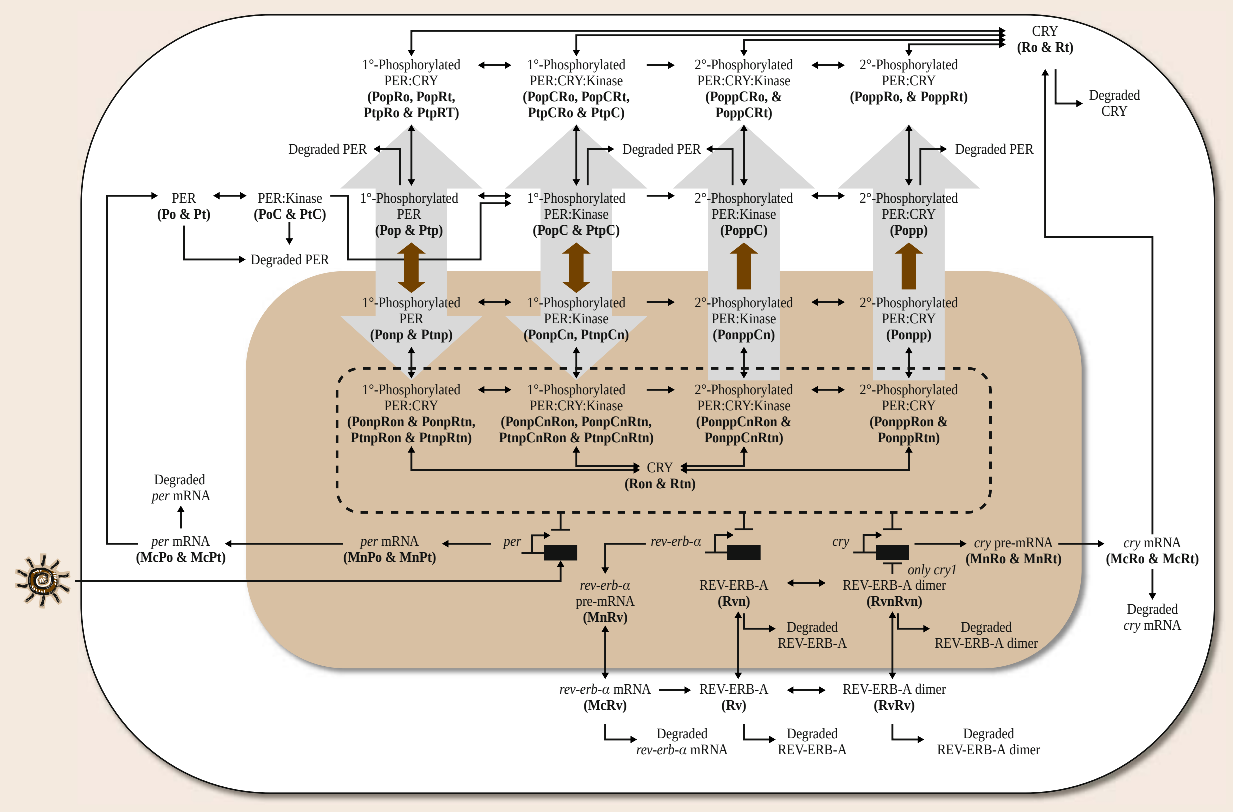

Fig. 75.2 Gene regulatory network underlying circadian rhythms in neurons in the SCN. Activated complexes of proteins inhibit the transcription of their corresponding genes, thus leading to time-delayed negative feedback and oscillations (after [75.30])

hypothalamus [75.24]. It is a network of multiple autonomous noisy (sloppy) oscillators, which communicate via neuropeptides to synchronize and form a coherent oscillator [75.25, 26]. At the core of the clock is a gene regulatory network in which approximately six key genes are regulated through an elegant array of time-delayed and coupled negative and positive feedback circuits (Fig. 75.2). The activity states of the proteins in this network are modulated (activated/inactivated) through a series of chemical reactions including phosphorylation and dimerization. These networks exist at the subcellular level. Above this layer is the signaling that leads to a synchronized response from the population of thousands of clock neurons in the SCN. Ultimately, this coherent oscillator then coordinates the timing of daily behaviors, such as the sleep/wake cycle. Left in constant (dark) conditions, the clock will run freely with a period of only approximately 24 h such that its internal time, or phase, drifts away from that of its environment. Thus, the ability to entrain to external time through environmental factors is vital to a circadian clock [75.27–29].

75.2.2 Apoptosis: Programmed Cell Death

Another example of biophysical networks is the apoptosis network in which an extracellular input controls the response of the cell as a result of this information processing network. Apoptosis is the programmed cell death machinery that is used by nature to strategically kill off unneeded and infected cells, but this mechanism often becomes impaired in cancer cells, leading to unchecked proliferation.

The specific example here is triggered by the Fas ligand. When an activated T-cell contacts a diseased cell, Fas and its natural ligand bind, resulting in the formation of the death inducing signalling complex (DISC). This complex then activates two pathways, both of which lead to the activation of the so-called executioner caspase 3. The Fas apoptotic network has been modeled by [75.31] using ordinary differential equations and is illustrated in Fig. 75.3. In the Type I pathway, a feedback pathway involving caspase-6 and caspase-8 regulates the amount of activated caspase-3. In the Type II pathway, Bcl-2 and active caspase-8 both interact with the mitochondrial membrane, regulating mitochondrial permeability. Caspase-8 allows mitochondria to become permeable, inducing the activation of the apoptosome and Smac (second mitochondrial-activator caspase) [75.32]. The activated apoptosome (Apopt_active) in turn activates caspase-3, while Smac can further enhance the activation of the executioner caspase by removing XIAP (X-linked inhibitor of apoptosis protein). FLIP, Bcl-2, and XIAP all antagonize the apoptotic signal and variations in their quantities can toggle the apoptotic signal between Type I and Type II activation or no activation at all. Experimental evidence has shown that Type I activation requires a significant amount of caspase-8 to be present in the cell. Yet, in Type II cells, mitochondrial activity ultimately enhances the death signal, significantly lowering the amount of caspase-8 that needs to be activated to induce apoptosis [75.33].

Understanding apoptosis in a broader sense will lead to a better knowledge of the common platform for emergence of cancer cells, and perhaps point to possible cures for certain types of cancer. The complexity of apoptosis, however, makes the understanding very difficult without a systems level approach using a mathematical representation of the pathway. Further, analysis of an apoptosis model can reveal the fragility points in the mechanism of programmed cell death that can have physiological implications not only for explaining the emergence of cancer cells but also for designing drugs or treatment for reinstating apoptosis in these cells. A robust performance analysis of an apoptotic network identified known network fragilities as well as new potential targets for therapeutic intervention. Such analyses are crucial to streamlining drug discovery in highly dynamic networks [75.34].

75.2.3 Signals in Diabetes: Insulin Signaling Pathway

In healthy cells, the uptake of glucose is regulated by insulin, which is secreted by β-cells in the pancreas.

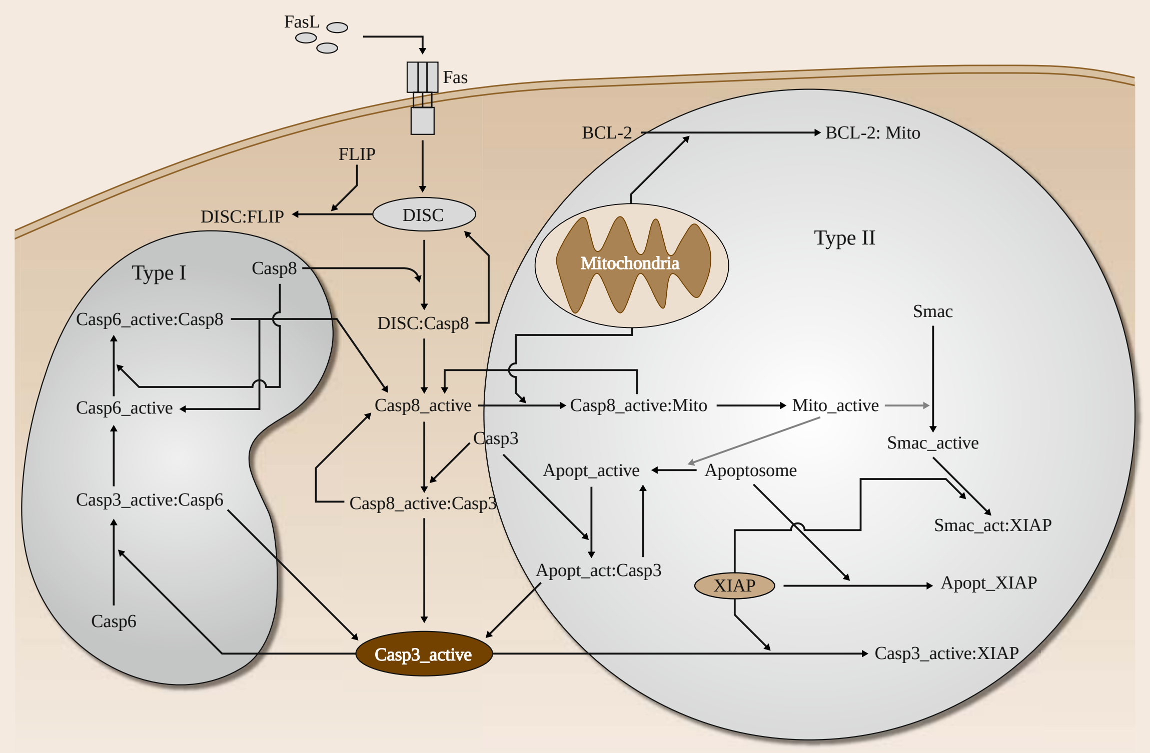

Fig. 75.3 Network schematic of the Type 1 and Type 2 Fas-induced apoptosis network (after [75.31])

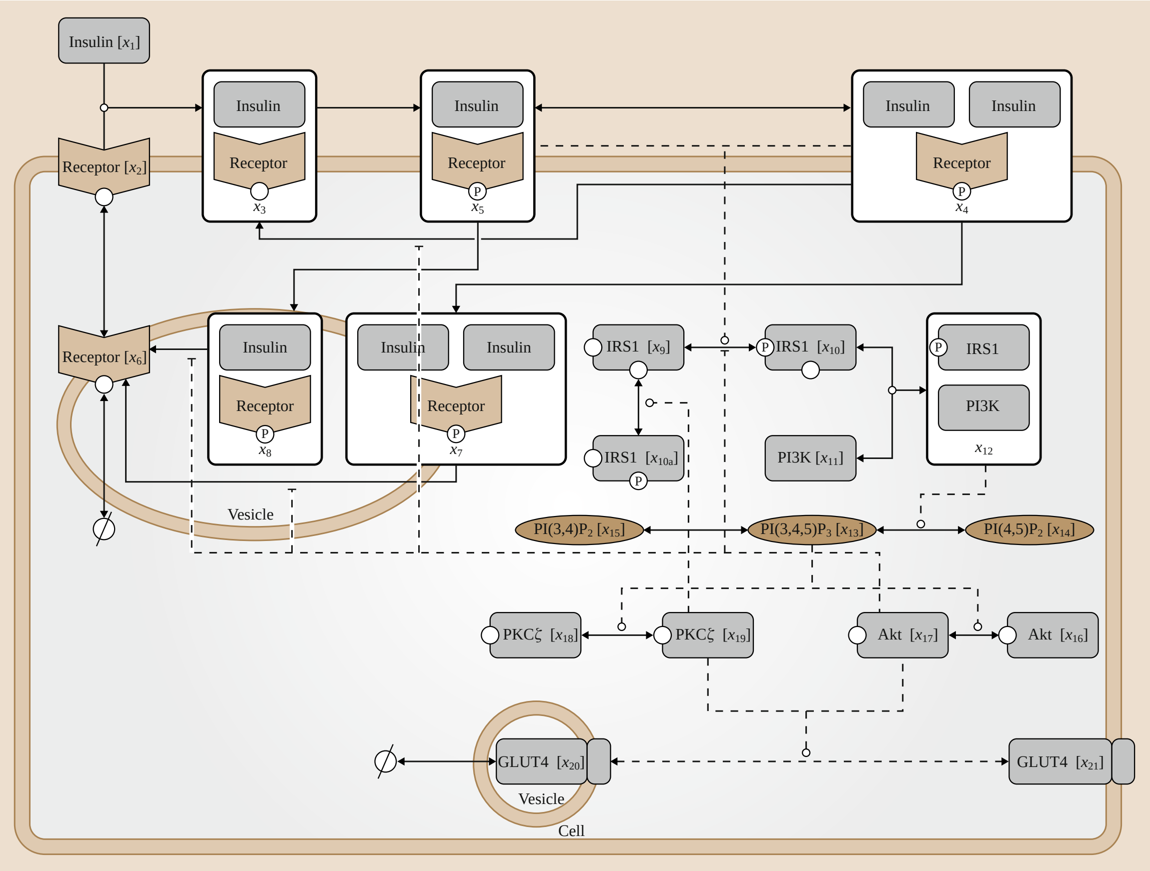

Fig. 75.4 Insulin signalling pathway model (after [75.35])

Simply stated, in patients with type 1 diabetes, the pancreas does not produce insulin, whereas in type 2 diabetes, among other consequences, the cells are resistant to the insulin produced by the pancreas. The latter phenomenon is best understood from detailed consideration of the insulin signalling pathway (illustrated in Fig. 75.4). The sequence of actions occurs as follows: (1) insulin binds to a receptor on the cell surface, which causes receptor autophosphorylation and activation; (2) the activated insulin receptor then phosphorylates insulin receptor substrate-1 (IRS1), which subsequently forms a complex with phosphatidylinositol-3-kinase (PI3K); (3) the IRS1-PI3K complex catalyzes the production of phosphatidylinositol triphosphate (PIP_3), which then interacts allosterically with phosinositide-dependent kinase 1 (PDK_1); (4) the PIP_3-PDK1 complex phosphorylates protein kinase Akt and protein kinase C (PKCζ); (5) activated Akt and PKCζ trigger glucose transporter (GLUT4) translocation from an internal compartment to the cell membrane. In a healthy cell, this cascade ultimately leads to uptake of glucose and helps to regulate glucose levels. In a cell characterized by type 2 diabetes, the cascade is desensitized to insulin, and the effectiveness of the signal is diminished.

75.3 Network Models for Structural Classification

An important point in systems biology is the integrative perspective, i. e., the analysis of the system considered as a whole and across the different levels (gene, protein, metabolite, etc.) and not the reductionist analysis of individual components. While it is useful to categorize the elements and levels of a hierarchical regulatory scheme, it is more useful to analyze such schemes for behaviors that emerge from combinations of simpler motifs. Some simple examples of canonical regulatory constructs (i. e., motifs) that yield specific classes of behavior in gene networks include [75.36]:

1. Positive feedback: multistability, oscillations, state-dependent response
2. Integral feedback: robust adaptation
3. Negative feedback: steady-state (homeostasis, adaptation)
4. Time delay: complex response, oscillations
5. Protein oligomerization: multistability, oscillations, resonant stimulus frequency response.

In addition, stochastic fluctuations can induce random response to stimuli, random outcomes, as well as stochastic focusing. Such properties are characteristic of general networks, including social networks, communication networks, and biological networks [75.37]. Given the wide variety of modeling objectives, as well as the heterogeneous sources of data, it is not surprising that many approaches exist for capturing network interactions in the form of mathematical structures.

75.3.1 Hierarchical Networks

Biophysical networks can be decomposed into modular components that recur across and within given organisms. One hierarchical classification is to label the top level as a network, which is comprised of interacting regulatory motifs consisting of groups of 2–4 components such as proteins or genes [75.38–40]. Motifs are small subnetworks that are over-represented compared to random networks with the same large-scale properties. At the lowest level in this hierarchy is the module that describes transcriptional regulation, of which a nice example is given in [75.41]. At the motif level, one can use pattern searching techniques to determine the frequency of occurrence of these simple motifs [75.39], leading to the postulation that these are basic building blocks in biological networks. Of relevance to the present discussion is the fact that many of these components have direct analogs in systems engineering architectures. Consider the three dominant network motifs found in *Escherichia coli* [75.39]:

1. Coherent feedforward loop: in this, one transcription factor regulates another factor, and, in turn, the pair jointly regulates a third transcription factor
2. Single input module (SIM): in systems terminology, a single-input multiple output block architecture
3. Densely overlapping regulons: in systems terminology, a multiple-input multiple output block architecture.

Similar studies in a completely different organism, *Saccharomyces cerevisiae*, yielded six related or overlapping network motifs [75.38]:

1. Autoregulatory motif: negative feedback in which a regulator binds to the promotor region of its own gene
2. Feedforward loop: as described earlier
3. Multicomponent loop: effectively, a closed-loop with two or more transcription factors
4. Regulator chain: a cascade of serial transcription factor interactions
5. Single input module: as described earlier (SIM)
6. Multiinput module: a natural extension of the preceding motif.

In effect, these studies provide strong evidence that, in both eukaryotic and prokaryotic systems, cell function is controlled by sophisticated networks of control loops that are cascading onto and interconnected with other (transcriptional) control loops. The noteworthy insight is that the complex networks, which underlie biological regulation, appear to be made of elementary systems components like a digital circuit. This lends credibility to the notion that analysis tools from systems engineering should find relevance in this problem domain.

75.3.2 Boolean Networks, Petri Nets, and Associated Structures

Boolean networks are abstract mathematical models employed for coarse-grained analysis of biophysical networks. A Boolean network is represented as a graph of nodes, with directed edges between nodes and a function for each node (e.g., [75.42]). Boolean networks are used to model network dynamics; for instance, a Boolean network can be used to model transcripts and proteins:

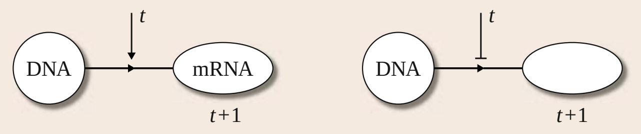

Fig. 75.5 Transcription of transcripts (mRNA)

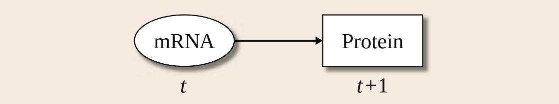

Fig. 75.6 Translation from transcripts to proteins

1. Transcripts and proteins are either on (1) or off (0).
2. The expression of a node at time step t is given by a logical rule of the expression of its effectors at time $t-1$.
3. Transcription depends on transcription factors; repressors are dominant (Fig. 75.5).
4. Translation depends on the presence of the transcript (Fig. 75.6).
5. Transcripts and proteins decay in one step if not produced.

Place/transition (P/T) nets, or Petri nets, introduced by Carl Adam Petri in 1962, have been intensively studied as one of several formal methods used to verify the correctness of systems, which are described as mathematical objects that can handle characteristics such as nondeterminism and concurrency (e.g., [75.43]).

There are several additional types of networks such as Bayesian nets, which combine directed acyclic graphs with a conditional distribution for each random variable (vertices in a graph, e.g., [75.44]), and signed directed graphs, in which a signed directed edge is used to represent activation versus inhibition (depending on the sign, e.g., [75.45]). Alternatively, S-systems (biochemical systems theory, BST) provide an approach wherein polynomial nonlinear dynamic nodes are used to capture network behavior (e.g., [75.46]).

75.4 Dynamical Models

While the consideration of motifs and network topology is essential for unraveling design principles in complex biophysical networks, it is necessary to understand the role of dynamic behavior in ascribing meaning to the rich hierarchies of regulation. Moreover, because of the interplay between topology and dynamics, it is often not enough in systems biology to specify only the nodes (components) and edges (interactions). The robust control of biophysical networks requires the answer to many challenging questions such as: (1) What are the dynamical aspects of the interaction? (2) What is the characteristic quantity changed by the interaction?

Some of the intrinsically dynamic features of biophysical networks have been analyzed in a recent paper that shows the close relationship between dynamic measures of robustness and the abundance of particular network motifs for a wide range of organisms [75.47]. Attempts to detail dynamic behavior in these networks have fallen into three broad classes of modeling techniques: (1) first-principles approaches, (2) empirical model identification, and (3) a hybrid approach that combines minimum biophysical network knowledge with an objective function to yield a predictive model. In this section, we outline some key results in the development of mechanistic models, and in the following section, we will address network identification.

Given detailed knowledge of a biological architecture, mathematical models can be constructed to describe the behavior of interconnected motifs or transcriptional units (TUs). A number of excellent review papers have been published in recent years [75.1, 36, 48, 49]. In the majority of these studies, gene expression is described as a continuous-time biochemical process, using combinations of algebraic and ordinary differential equations (ODEs) [75.12, 36, 50]. In a similar manner, models at the signal transduction pathway level have been developed in a continuous-time framework, yielding ODEs [75.51]. At the TU level, a detailed mathematical treatment of transcriptional regulation is described in [75.41]. Mechanistic models for a number of specific biological systems have been reported, including basic operons and regulons in *E. coli* (trp, lac, and pho) and bacteriophage systems (T7 and λ) [75.52].

Systems theory has found an enabling role in the analysis of the complex mathematical structures that result from the previously described modeling approaches. The language of systems theory now dominates the quantitative characterization of biological regulation, as robustness, complexity, modularity, feedback, and fragility are invoked to describe these systems. Even classical control theoretic results, such as the Bode sensitivity integral, are being applied to describe the inherent tradeoffs in sensitivity across frequency [75.53]. Robustness has been introduced as both a biological system-specific attribute, as well as a measure of model validity [75.54, 55]. In the next section, brief accounts of systems-theoretic analysis of biological regulatory structures are given, emphasizing where new insights into biological regulation have been uncovered.

75.4.1 Stochastic Systems

Discrete stochastic modeling has recently gained popularity owing to its relevance in biological processes [75.8, 56–59] that achieve their functions with low copy numbers of some key chemical species. Unlike the solutions to stochastic differential equations, the states/outputs of discrete stochastic systems evolve according to discrete jump Markov processes, which naturally lead to a probabilistic description of the system dynamics. A first-order Markov process is a random process in which the future probabilities are dependent only on the present value, and not on past values. Such descriptions can find relevance in systems biology when the magnitude of the fluctuations in a stochastic system approaches the levels of the actual variables (e.g., protein concentrations). In addition, there are qualitative phenomena that are intrinsic to such descriptions that arise in biological systems, as will be mentioned later.

The idea that stochastic phenomena are essential for understanding complex transcriptional processes was nicely illustrated by *Arkin* and coworkers in the analysis of the phage λ lysis–lysogeny decision circuit [75.8]. The probabilistic division of the initially homogeneous cell population into subpopulations corresponding to the two possible fate outcomes was shown to require a stochastic description (and could not be described with a continuous deterministic model). In particular, the coexistence of the two subpopulations necessitated such a formal characterization, and the relative sensitivity of the subpopulations to model parameters including external variables could be analyzed with the resulting models. In a more recent work, *Samilov* and coworkers [75.60] have shown another example of a biological behavior that is intrinsically stochastic in nature – namely the dynamic switching behavior in a class of biochemical reactions (enzymatic futile cycles). In this case, the behavior is more subtle than the lysis–lysogeny switch, where the existence of a bifurcation was at least evident in the continuous differential equation model. In the enzymatic futile cycle problem, the deterministic model gives no indication of multiplicity, yet the discrete stochastic model generates behaviors, including switching as well as oscillations, that indicate characteristics of bifurcation regimes. It is suggested that such noise-induced mechanisms may be responsible for control of switch and cycle behavior in regulatory networks.

In the discrete stochastic setting, the states and outputs are random variables governed by a probability density function, which follows a chemical master equation (CME) [75.61]. The rate of reaction no longer describes the amount of chemical species being produced or consumed per unit time in a reaction but rather the likelihood of a certain reaction to occur in a time window. Though analytical solution of the CME is rarely available, the density function can be constructed using the stochastic simulation algorithm (SSA) [75.61].

The discrete stochastic system of interest is described by a CME [75.62]

$$\begin{aligned}\frac{\mathrm{d}\,f(\boldsymbol{x},t|\boldsymbol{x}_0,t_0)}{\mathrm{d}t} &= \sum_{k=1}^{m} a_k(\boldsymbol{x}-\boldsymbol{v}_k,\boldsymbol{p})\,f(\boldsymbol{x}-\boldsymbol{v}_k,t|\boldsymbol{x}_0,t_0)\\ &\quad - a_k(\boldsymbol{x},\boldsymbol{p})\,f(\boldsymbol{x},t|x_0,t_0)\,, \qquad (75.1)\end{aligned}$$

where $f(x,t|x_0,t_0)$ is the conditional probability of the system to be at state x and time t, given the initial condition x_0 at time t_0. The state vector x gives the molecular counts of the species in the system. Here, a_k denotes the propensity functions, v_k denotes the stoichiometric change in x when the k-th reaction occurs and m is the total number of reactions. The propensity function $a_k(x,p)\,\mathrm{d}t$ gives the probability of the k-th reaction to occur between time t and $t+\mathrm{d}t$, given the parameters p. As the state values are typically unbounded, the CME essentially consists of an infinite number of ODEs, whose analytical solution is rarely available except for a few simple problems. The SSA provides an efficient numerical algorithm for constructing the density function [75.61]. The algorithm follows a Monte Carlo approach based on the joint probability for the time to and the index of the next reaction, which is a function of the propensities. The SSA indirectly simulates the CME by generating many realizations of the states (typically of the order of 10^4) at specified time t, given the initial condition and model parameters, from which the distribution $f(x,t|x_0,t_0)$ can be constructed.

There has been simultaneous advancement in experimental methods for quantifying the characteristics of biological noise [75.63–65] along with advances in computing and simulation. A number of groups have recently used dual reporter methods to track the activity of identical genes in the same cell to measure the impact of noise on expression. In the work of *Elowitz* and coworkers, the separate effects of stochastic behavior in the transcriptional and translational processes in prokaryotes (so-called intrinsic noise) are distinguished from noise effects arising from other cellular components that influence the rate of gene expression (so-called extrinsic noise [75.63,65]). *Raser* and *O'Shea* analyze eukaryotic systems with both cis-acting and trans-acting mutations to distinguish between the noise effects that are intrinsic to transcription as opposed to upstream processes that might ultimately influence expression [75.64].

The interface of discrete stochastic systems and biology has clearly led to new insights into stochastic phenomena in biological systems, and has also spurred the development of more efficient computational methods for stochastic simulation, as well as analysis methods for these models. This interface will continue to motivate developments in systems engineering, with improved methods for imaging biological systems that include the ability to resolve spatial behaviors. Distributed stochastic models will require more sophisticated algorithmic developments, particularly as one builds models to truly address systems-scale phenomena.

75.4.2 Constraints and Optimality in Modeling Metabolism

To understand complex biological systems, instead of starting from actual implementations and observations, one can reduce the problem by first separating the possible from the impossible, such as configurations and behaviors that would violate constraints. Systems approaches try to exploit three broad classes of constraints:

1. Empirical: large-scale experimental analysis can provide constraints on possible network structures, such as the average or maximal number of interactions per component.
2. Physico-chemical: laws qof physics such as conservation of mass and thermodynamics impose constraints on cellular and network behaviors. These are used, in particular, for structural network analysis (SNA) with roots in the analysis of chemical reaction networks [75.66].
3. Functional: biological systems perform certain functions and their building blocks are confined to a large, yet finite set. Network structures and behaviors have to conform with both aspects.

Functional constraints constitute the main differences between complex physics and biology. In physics, they do not exist. Biological (as well as engineered) systems evolve to fulfill functions, and are constantly evaluated for their performance. Insufficient performance will lead to extinction, and better solutions are likely to survive. Hence, it is reasonable to assume some kind of optimality in biological systems. The immediate consequence of a purpose is a considerably smaller design space, in which effective and reliable network are rare and presumably highly structured. Understanding complexity in biology could, thus, employ a calculus of purpose – by asking teleological questions such as why cellular networks are organized as observed, given their known or assumed function [75.67].

Physico-chemical Constraints in Metabolism

Essential constraints for the operation of metabolic networks are imposed by (1) reaction stoichiometries, (2) thermodynamics that restrict flow directions through enzymatic reactions, and (3) maximal fluxes for individual reactions. For instance, metabolism usually involves fast reactions and high turnover of substances when compared with regulatory events. Therefore, on longer time-scales, it can be regarded as being in quasi-steady state. The metabolite balancing equation (75.2) for a system of m internal metabolites and q reactions with the $m \times q$ stoichiometric matrix $\mathbf{N}$ and the $q \times 1$ vector of reaction rates (fluxes) $\boldsymbol{r}$ formalizes this main constraint in SNA. As for most real networks $q \gg m$, the system of linear equation (75.2) is underdetermined. However, all possible solutions are contained in a convex vector space, or flux cone (Fig. 75.7). Methods from convex analysis allow to investigate this space [75.68, 69]

$$\frac{\mathrm{d}\boldsymbol{x}(t)}{\mathrm{d}t} = \mathbf{N} \cdot \boldsymbol{r} = 0\,. \tag{75.2}$$

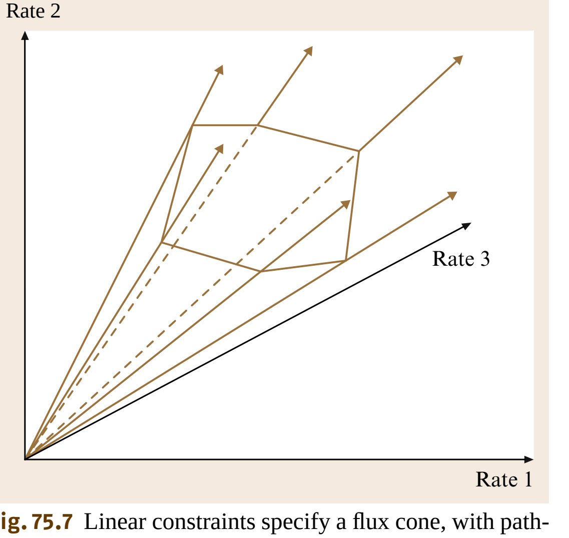

Fig. 75.7 Linear constraints specify a flux cone, with pathways as generating rays, projection on three-dimensional flux space (after [75.4])

Two broad classes of methods for SNA have been developed: metabolic pathway analysis (MPA) and flux balance analysis (FBA) [75.70–72]. MPA computes and uses the set of independent pathways-generating rays in Fig. 75.7 – that uniquely describe the entire flux space; owing to the algorithmic complexity, it can currently only handle networks of moderate size. FBA, in contrast, determines a single flux solution through linear optimization [75.73], often assuming that cells try to achieve optimal growth rates. The computational costs are modest, even for genome-scale models. The approach was successful, for instance, in predicting the effects of gene deletions and the outcomes of convergent evolution in microorganisms [75.72, 74, 75]. FBA, however, has to reverse-engineer and operate with an essentially unknown objective function. While maximal growth has proven to be a reasonable assumption for lower organisms [75.76], higher cells may tend to minimize overall fluxes in the network [75.77]. In general, FBA has proven effective for simpler organisms, and when the steady-state assumption is valid. However, there are many situations where these conditions do not apply, many of which are biophysically meaningful, such as the dynamic diauxic shift in *E. coli*.

Extensions: Dynamics and Control

Stoichiometric constraints restrict the systems dynamics. Thus, the stoichiometric matrix $\mathbf{N}$ is fundamental not only for SNA but also for dynamic processes in reaction networks, in which the reaction rates $\boldsymbol{r}$ in (75.2) are time-dependent. For biological systems, the conservation of total amounts of certain molecular subgroups (conserved moieties such as ATP, ADP and AMP) is characteristic and can be exploited for systems analysis. Classical work in chemical engineering addressed this topic for chemical reaction networks. For instance, *Feinberg* derived theorems to determine the possible dynamic regimes, such as multistability and oscillations, based on network structure alone [75.78, 79]. Challenges posed by biological systems led to renewed interest in these approaches and induced further theory development [75.80, 81]. Application areas in biology include stability analysis [75.80] and model discrimination by safely rejecting hypotheses on reaction mechanisms, thus identifying crucial reaction steps [75.82]. Algorithms for the identification of dependent species in large biochemical systems – to be employed, for instance, in model reduction – have recently become available [75.83].

Enabling FBA to deal with dynamics and regulation proceeded by incorporating additional time-dependent constraints that reflect knowledge of the operation of cellular control circuits – an approach termed regulatory FBA [75.84]. For instance, using superimposed Boolean logic models to capture transcriptional regulatory events has extended the validity of the methodology for a number of complex dynamic system responses [75.84] and for data integration [75.85]. Other dynamic extensions of the FBA algorithm have been proposed in [75.86]. With these more detailed models, steady-state analysis suggested that the complex transcriptional control networks operate in a few dominant states, i. e., generate simple behavior [75.87]. Finally, pathway analysis also allows one to approach features of intrinsically dynamic systems: for instance, it helps to identify feedback loops in cellular signal processing [75.88]. Hence, SNA-related approaches are about to extend to nonclassical domains, in particular, through theory development induced by new challenges in systems biology.

Functional Constraints, Optimality, and Design

In analyzing living systems, one possibility is to start from the assumptions that they have to fulfill certain functions and that cells have been organized over evolutionary time-scales to optimize their operations in a manner consistent with mathematical principles of optimality. FBA demonstrates the utility of this assumption; note that its implicit functional constraint, i. e., steady-state operation of metabolic networks, is not self-explanatory. Similarly, other approaches invoking principles of optimal control theory have opened new avenues for systems analysis in biology.

The cybernetic approach developed by *Kompala* et al. [75.89] and *Varner* and *Ramkrishna* [75.90] is based on a simple principle: evolution has programmed or conditioned biological systems to optimally achieve physiological objectives. This straightforward concept can be translated into a set of optimal resource allocation problems that are solved at every time-step in parallel with the model mass balances (basic metabolic network model). Thus, at every instant in time, gene expression and enzyme activity are rationalized as choice between sets of competing alternatives, each with a relative cost and benefit for the organism. Mathematically, this can be translated into an instantaneous objective function. The researchers in this area have defined several postulates for specific pathway architectures, and the result is a computationally tractable (i. e., analytical) model structure. The potential shortcoming is a limited handling of more flexible objective functions that are commonly observed in biological systems [75.91–95].

Instead of focusing on a single objective function, mathematical models and experimental data can be used to test hypotheses on optimality principles, given a specific cellular function to be fulfilled. For instance, extensions of FBA suggested that *E. coli* optimizes the tradeoff between achieving high growth rates and maintaining wild-type metabolic fluxes after gene deletions [75.96]. MPA showed that the interplay between the metabolic network (the controlled plant) and gene regulation (the controller) in *E. coli* might be designed to achieve optimal tradeoffs between long-term objectives, such as metabolic flexibility, and short-term adjustment for metabolic efficiency [75.97]. Optimal production pipelines for biomass components, with fast responses to environmental changes and minimal additional efforts for enzyme synthesis, were predicted in detail to employ wave-like gene expression programs, which was later confirmed experimentally [75.77, 98]. Hence, at least certain cellular design principles can be revealed by evaluating assumptions on cellular optimality principles.

Finally, without assuming optimality, we can ask how functions in biological systems could be established in principle. Among others, drawing from analogies with engineered systems helps to understand more general design principles in biology. From nonlinear dynamics, for instance, it is well-known that functions such as oscillators and switches require some source of nonlinearity. Establishing such a function with biological building blocks, thus, allows only for certain circuit designs [75.99,100]. Similar ideas can prove powerful at different levels of abstraction. For instance, highly structured bow-ties with multiple inputs, channeled through a core with standardized components and protocols to multiple outputs, could be the common organizational principles to establish complex production systems in engineering and biology [75.53]. On the other hand, *El-Samad* and colleagues studied the bacterial heat-shock response, pointing out that the intertwined feedback and feedforward loops present can be assigned individual functions parallel to those loops in designed control circuits that have to yield fast responses in highly fluctuating environments [75.101]. Notably, most of the examples discussed here involved new developments in theory to address challenges posed by biology.

75.5 Network Identification

Model development involves the translation of identified biological processes to coupled dynamical equations, which are amenable to numerical simulation and analysis. These equations describe the interactions between various constituents and the environment, and involve multiple feedback loops responsible for system regulation and noise attenuation and amplification. Currently, however, our knowledge of essentially all biological systems is incomplete. Despite genome projects that allow enumeration and, to a certain extent, characterization of all genes in a system, this does not imply knowledge about all network components (for instance, all protein variants that can be derived from a single gene), interactions, and properties thereof [75.22]. An important task in systems biology consists of specifying network interactions, which can concern qualitative or quantitative properties (existence and strength of couplings), or detailed reaction mechanisms, for genome-based inventories of components.

Essentially, this is a systems identification problem. Given a set of experimental data and prior knowledge, the network generating the data is to be determined [75.102]. Alternatively termed *reverse engineering* [75.103], *network reconstruction* [75.104] or *network inference* [75.105], the general network identification problem provides a key interface between science and engineering. Several qualitatively different approaches for biological systems have been proposed, which can be roughly classified into three categories: data-driven, approximative and mechanistic.

75.5.1 Data-Driven Methods

Empirical or data-driven methods rely on large-scale datasets that can be generated, for instance, through microarray analysis for gene regulatory networks. The relevant methods include singular value decomposition analysis of microarray data [75.106, 107], self-organizing maps [75.108], k-means clustering or hierarchical clustering [75.109], protein correlation and dynamic deviation factors [75.110], and robust statistics approaches [75.111, 112]. For instance, clustering methods are routinely applied for identifying groups of coregulated genes from microarray data. The interpretation of clustering results employs (implicit) models such as coexpressed genes that are likely to have a common regulator. Data quality and algorithmic choices (for instance, of distance measures) critically influence the clustering results; in addition, validation of clustering results and techniques is an open issue [75.113–115].

In contrast to the mechanistic approaches discussed later, most empirical approaches employ discrete-time gray box models [75.116–119]. For instance, inference methods based on probabilistic graphical (e.g. Bayesian) models help to elucidate causal couplings between the network components [75.120]. Their scalability for large systems and the ability to integrate heterogeneous datasets make them attractive [75.5, 121]. Yet, these approaches deliver only qualitative descriptions of network function, and have inherent limitations. For instance, Bayesian models cannot cope with the ubiquitous feedback in cellular networks, since causal relationships have to be represented by directed acyclic graphs [75.120].

A number of challenges are present in treating experimental data for such problems: (1) the sampling rate is rarely uniform and may be exponentially spaced by design, and (2) data from multiple research groups are often combined (e.g. from WWW-posted data) to yield data records with inconsistent sampling, experimental bias, etc. From a systems engineering perspective, another critical point is the potentially divergent qualitative behavior between continuous-time and discrete-time models of corresponding order [75.122]. Recent work has shown the promise of continuous-time formulations of empirical models using modulating function approaches [75.40].

More generally, correctly identifying network topologies (corresponding to the model structure) clearly does not suffice for establishing predictive mathematical models. Experiences with engineered genetic circuits illustrate this point: with identical topology, qualitatively different behavior can result and vice versa [75.123]. Hence, quantitative characteristics, which are usually incorporated through parameters in deterministic models, are also required. Corresponding identification methods are rooted in systems and information theory and, thereby, also provide the largest intersection among biology, other sciences, and engineering.

75.5.2 Linear Approximations

The identification of dynamically changing interactions requires corresponding dynamic models. In a first approximation, we can consider linear systems, i. e., systems with additive responses to perturbations. In systems engineering, a standard form for linear time-invariant (where the shape of the output does not change with a delay in the input) systems with n states and m inputs is given by (75.3) with $n \times 1$ state vector $\boldsymbol{x}(t)$, $n \times n$ system matrix $\mathbf{A}$, $n \times m$ input matrix $\mathbf{B}$, and $m \times 1$ input vector $\boldsymbol{u}(t)$. Linearization of the general dynamic system $\mathrm{d}\boldsymbol{x}(t)/\mathrm{d}t = f(\boldsymbol{x}, \boldsymbol{p}, t)$ with parameter vector $\boldsymbol{p}$ provides first approximations to the network dynamics, even for highly nonlinear systems such as those encountered in biological networks. Linear models capture the local dynamics, for instance, in the vicinity of a steady state, instead of aiming at more complicated global behaviors.

$$\frac{\mathrm{d}\boldsymbol{x}(t)}{\mathrm{d}t} = f(\boldsymbol{x}, \boldsymbol{p}, t) \approx \mathbf{A}\boldsymbol{x}(t) + \mathbf{B}\boldsymbol{u}(t) \tag{75.3}$$

Mathematically, most methods reconstruct the system matrix $\mathbf{A}$, which corresponds to the Jacobian matrix $\mathbf{J} = \partial f(\boldsymbol{x}, \boldsymbol{p})/\partial \boldsymbol{x}$, from the measured effects of (sufficiently small) perturbations. However, direct recovery of the system matrix $\mathbf{A}$ will be unreliable with noisy data and inputs. In a study using linear models and perturbation experiments to identify the structure of genetic networks, *Tegner* et al. [75.103] therefore proposed an iterative algorithm that uses rational choices of perturbations to improve the identification quality. For a developmental circuit, despite high nonlinearities in the system, the reverse engineering algorithm, which involves building and refining an average connectivity matrix in successive steps, recovered all genetic interactions [75.103]. A related approach that uses linear models and multiple linear regressions showed similar performance. The algorithm attempts to exploit the sparsity of systems matrices for biological networks owing to, for example, (estimated) upper bounds on the number of connections per node [75.105, 124]. Both algorithms are scalable – a central concept in engineering, but until recently considered of less importance in biology.

Newer approaches to systems identification aim at exploiting modularity in biological networks. For a modular system with one output per module, the method employs inversion of the global response matrix for identification of network connectivities and of local responses from perturbation experiments [75.125]. It requires a reduced number of measurements compared with other methods because only changes in so-called communicating intermediates have to be recorded. Apparently, some simplifying assumptions have to be made; for example, modules are coupled by information flow only, and mass flow is negligible [75.125]. An important result of extending the modular identification to time-series data is that, for identifying all connections of a node, it is not necessary to perturb this node directly – inference can rely on detecting the network responses to remote perturbations [75.126]. Extensions to include the effects of uncertainties in experimental data and prior knowledge [75.127], and the possibility of a unified mathematical framework [75.128] make modular identification methods particularly promising.

75.5.3 Mechanistic Models, Identifiability and Experimental Design

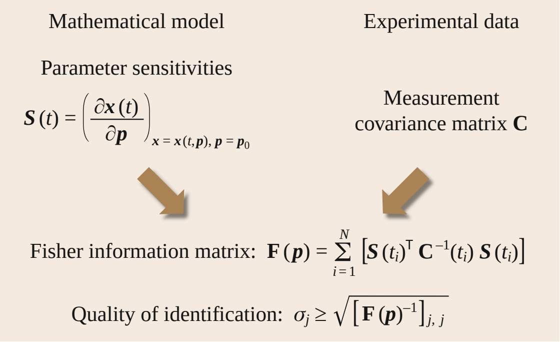
Mechanistic models, owing to effects such as saturation in enzymatic reactions, pose particular challenges because they involve identification of nonlinear systems. Depending on whether model structure and parameters, or only the parameters have to be identified, the problems fall into the classes of mixed-integer nonlinear programs or nonlinear programs, respectively. As a clear limitation, finding a unique global optimum in the estimation, or convergence of the algorithms cannot be guaranteed. In addition, model identification comes at high computational costs owing to numerous model simulations [75.129].

In terms of parameter estimation, which is a common problem in different scientific domains [75.102], realistic modeling of complex, nonlinear dynamics of biological networks has given new impulses for the evaluation of existing methods and development of new methods. For instance, though stochastic algorithms show superior performance over deterministic methods for parameter optimization in these systems, they are computationally expensive [75.130]. Novel hybrid methods try to exploit synergies between both approaches in order to increase robustness and efficiency (e.g. [75.131, and references therein]).

More fundamentally, *identifiability* and design of informative experiments need to be addressed. Unstructured approaches to model identification are completely ill-posed when faced with, for instance, modeling a yeast cell with 6200 genes and four possible states per gene; we obtain an overall expression state dimension in excess of 10^{15} [75.132]. Clearly a number of a priori constraints and correlations must be exploited. For discrete models, usage of the experimentally observed upper bound on the number of interactions per species brings the amount of data needed for identification into realistic dimensions [75.133]. However, mere extrapolation of current high-throughput technology will not solve these high dimensional data issues. Several recent studies have highlighted the importance of proper design of perturbations to reveal the logical connectivity of gene networks [75.104, 134]. Systems engineering concepts of experimental design to provide rich datasets can be exploited to develop predictive mechanistic models.

Parameter estimation accuracies are central to measuring identifiability of mechanistic models. Low accuracies mean that the corresponding parameters may be varied to a greater extent – and still describe the data – than it is possible for parameters with high estimation accuracy (low associated error). They combine information on model sensitivities with experimental data (Fig. 75.8). More specifically, the Fisher information matrix (FIM) $\mathbf{F}(\boldsymbol{p})$ [75.135], for a point in parameter space p, links model and experiment via state sensitivities $\boldsymbol{S}(t) = \partial \boldsymbol{x}/\partial \boldsymbol{p}$ and measurement covariance matrix for a discrete sampling time t_i, $\mathbf{C}(t_i)$. For an unbiased estimator, the Cramér–Rao theorem then gives a lower bound for the estimation error (minimum variance).

FIM-based approaches, for instance, yielded insight into the importance of suitable design of input perturbations for signaling networks [75.40], optimality criteria for the design of such inputs [75.136], and algorithms for the optimization of sampling times for dynamic experiments [75.137]. New hybrid parameter estimation methods [75.131] and closed-loop (i. e., integrating iterations between estimation, evaluation of the identifiability, and experimental design) optimal identification procedures [75.138] rely on the FIM formalism. Note, however, that while these proof-of-concept studies with small models and synthetic data are valuable, the performance for real biological problems awaits assessment.



Mathematical model
Experimental data
Parameter sensitivities
$\boldsymbol{S}(t) = \left(\frac{\partial \boldsymbol{x}(t)}{\partial \boldsymbol{p}}\right)_{\boldsymbol{x}=\boldsymbol{x}(t,\boldsymbol{p}),\, \boldsymbol{p}=\boldsymbol{p}_0}$
Measurement covariance matrix $\mathbf{C}$
Fisher information matrix: $\mathbf{F}(\boldsymbol{p}) = \sum_{i=1}^{N} \left[\boldsymbol{S}(t_i)^{\mathrm{T}}\, \mathbf{C}^{-1}(t_i)\, \boldsymbol{S}(t_i)\right]$
Quality of identification: $\sigma_j \geq \sqrt{\left[\mathbf{F}(\boldsymbol{p})^{-1}\right]_{j,j}}$

Fig. 75.8 FIM and identification quality. The lower bound for the estimation error of parameter j, σ_j, is derived from the inverse of the main diagonal of the FIM (after [75.4])

Information-rich datasets for integrative models will have to be derived from sources across all levels of biological regulation, such as the transcriptome, proteome, and metabolic fluxes. Concomitantly, we need novel statistical frameworks for data integration [75.139]. Systems identification would greatly benefit from the direct in vivo determination of kinetic parameters; the work by *Ronen* et al. [75.140] for transcriptional control is a first step in this direction. As a complement, synthetic genetic circuits could provide means for controlled excitation of the system, for instance, by inducible genetic switches [75.103], or through genetic oscillators to incorporate analysis methods in the frequency domain [75.102]. Novel methods could also take known uncertainties associated with measurements, such as experimentally determined characteristics of stochastic noise, explicitly into account. Finally, identification depends on adequate specification of the system and model (e.g., [75.141]). While models are currently either set up ad hoc, or through manual comparison of few alternative structures (including kinetic terms in the equations), uncertainties in biology pose a major challenge for systems sciences: deriving advanced approaches to model discrimination for the simultaneous identification of model structures and parameters.

75.6 Quantitative Performance Metrics

In biology, as in engineering, robust performance refers to the attainment of a particular behavior or response by a system in the presence of uncertainty. This appears to be a ubiquitous property of biological processes that are subject to constant uncertainty in the form of stochastic phenomena [75.142], fluctuating environment, and genetic variation (reviewed in [75.15]). Biology has adapted a number of approaches for coping with these sources of uncertainty, which include:

1. Back-up systems (redundancy)
2. Disturbance attenuation through feedback and feed forward control
3. Structuring of networked systems into semi-autonomous functional units (modularity)
4. Reliable coordination of network elements through hierarchies and protocols.

The robustness problems in systems biology have only begun to yield, in recent years, formal quantitative analyses, owing largely to their nonlinear (and nonstationary) nature. As with engineering systems, robust performance requires the precise specification of both a performance metric and the type/size of uncertainty. When both these elements are specified, it may be possible to analyze biological systems with established engineering tools. It is important to note that the performance metric is often difficult to be defined precisely in biology, as it is an implicit element of an evolved entity.

The last 10 years have demonstrated that sensitivity analysis can provide unique insights into the functioning of complex biophysical networks [75.4, 143–145]. Of particular interest is the behaviour of biological circuits that exhibit oscillations (e.g., circadian rhythm, cell cycle, neuron firing, cardiac cycles, etc.). In [75.146], a novel set of sensitivity metrics was introduced for performance that were based on a number of different phase-measures: period, phase, corrected phase, and relative phase. The motivation was that phase appears to be the biological imperative, rather than period, for optimal regulation of circadian rhythms. Both state-based and phase-based tools were applied to free-running (absence of light/dark cycles) *Drosophila melanogaster* and *Mus musculus* circadian models. Each metric produced unique relative sensitivity measures used to rank parameters from least to most sensitive. Similarities among the resulting rank distributions strongly suggested a conservation of sensitivity with respect to parameter function and type. A consistent result, for instance, is that model performance of biological oscillators is more sensitive to global parameters than local (i. e., circadian specific) parameters. Differences across the metrics revealed that the conclusions about robustness were dependent on the metric employed for performance.

In [75.147], a novel sensitivity measure, the parametric impulse phase response curve (pIPRC), was derived to both characterize the phase behavior of an oscillator and provide the means for computing the response to an arbitrary signal (in the form of parametric perturbation). The pIPRC builds on the knowledge that biologists have collected for decades in the form of phase response curves (PRCs), to more general classes of input perturbations. The PRCs and infinitesimal PRCs presented in that study provided quantifiable measures of robustness for oscillators acting as pacemakers. In these systems, robust performance involves proper maintenance of phase behavior. In the case of the circadian clock, this means that the PRC to light must have not only the proper shape, but also the correct magnitude. *Zeilinger* et al. [75.148] were able to invalidate a model of the circadian clock in the plant *Arabidopsis thaliana*, because the pIPRC had neither the proper shape nor the proper magnitude.

In [75.149], sensitivity methods were employed to predict the likelihood that noise propagates in stochastic models of the circadian network. The results showed that noise introduced into a sensitive point in the clock propagates very well, while noise introduced into an insensitive (or robust) point is undetectable elsewhere. The noise propagates without regard to distance from point of introduction to point of measurement. It was concluded that the sensitive global parameters are the sites of effective noise propagation in the clock. The hypothesis was that global parameters govern reactions at critical points in the network and therefore may suggest those parts of other systems most worthy of investigation.

The previous studies focused on single cell models, but network properties must also be analyzed at higher levels in the system. *Bagheri* et al. [75.150] demonstrated that computational techniques applied to single cell data are fundamental for tuning and predicting the behavior of oscillatory phenomena at the population level [75.151], since the results of such investigations point to the coupling mechanisms that give rise to spontaneously synchronized networks of stochastic biophysical nodes. Without such insight, it would not have been possible to reproduce the synchrony observed in the SCN. As a result, it is important for experimental biologists to adopt the tools necessary to analyze the structure of both in vitro and in vivo systems.

75.6.1 State-Based Sensitivity Metrics

Parametric state sensitivity is captured in an m by n matrix consisting of individual state performance values with respect to isolated parametric perturbations. The direct method [75.152, 153] is a means to determine exact parametric state sensitivity measures, $S_{ij}(t)=\mathrm{d}x_i(t)/\mathrm{d}\rho_j$. This approach relies on the continuity of $f[\boldsymbol{x}(t),\boldsymbol{\rho}]$ with respect to the parameter vector ρ. Applying the chain rule results in partial derivatives of the function with respect to states and parameters produces an ordinary differential equation of sensitivity dynamics (75.4). The initial conditions for the sensitivities are zero unless the system initial conditions x_0 depend on the parameters.

$$\dot{\mathbf{S}}(t)=\frac{\partial f[\mathbf{x}(t),\boldsymbol{\rho}]}{\partial \mathbf{x}}\bullet\mathbf{S}(t)+\frac{\partial f[\mathbf{x}(t),\boldsymbol{\rho}]}{\partial \boldsymbol{\rho}} \qquad (75.4)$$

In oscillatory systems, coefficients of raw state sensitivity, $\mathbf{S}(t)=\mathrm{d}\mathbf{x}(t)/\mathrm{d}\boldsymbol{\rho}$, rely on multiple coupled outputs (such as period and phase) and grow unbounded in time for parameters whose period sensitivities are nonzero [75.154–156]. The secular term is due to computation of sensitivities involving a nonuniformly valid expansion of a periodic system [75.154]. *Tomovic* and *Vukobratovic* [75.155] demonstrate that state sensitivity, evaluated at the constant nominal period τ, provides a specific measure corresponding to limit cycle behavior. This measure is unbiased to changes in the period/frequency of oscillation. The resulting m by n matrix is referred to as the cleaned-out or shape sensitivity measure $\mathbf{S}^{\mathrm{C}}(t)=(\partial\mathbf{x}(t)/\partial\boldsymbol{\rho})_{\tau}$; $\mathbf{S}^{\mathrm{C}}(t)$ is periodic in time and describes how parametric perturbations affect the shape of state trajectories [75.154]. In its raw form, state sensitivity for oscillatory systems may be decomposed into a combination of shape and period sensitivity measures (75.5) [75.155]. This decomposition of raw state sensitivity highlights its linear time growth t/τ while isolating period sensitivity, $\mathbf{S}^{\tau}=\mathrm{d}\tau/\mathrm{d}\rho$. The decomposition is generally accomplished by calculating state and period sensitivities, and then solving for the cleaned-out shape sensitivity matrix.

$$S(t)=S^{\mathrm{C}}(t)-\frac{t}{\tau}f[x(t),\rho]\frac{\mathrm{d}\tau}{\mathrm{d}\rho} \qquad (75.5)$$

Zak et al. [75.156] proposed a method to determine period sensitivity $\mathbf{S}^{\tau}$ by making use of the decomposition (75.5) and evaluating state sensitivities at a large time $t_1\gg\tau$. At this time, the second term on the right-hand side of (75.5) dominates the cleaned-out sensitivity matrix. Singular value decomposition of state sensitivity produces $\mathbf{S}(t_1)=\mathbf{U}\boldsymbol{\Sigma}\mathbf{V}^{\top}$, where $\boldsymbol{\Sigma}$ is an m by n diagonal matrix of nonnegative singular values σ and matrices $\mathbf{U}$ and $\mathbf{V}$ contain the eigenvectors of $\mathrm{SS}^{\top}$ and $\mathbf{S}^{\top}\mathbf{S}$, respectively. Hence, period sensitivity of any given state may be approximated by (75.6) where σ_1 is the largest singular value in $\boldsymbol{\Sigma}$, $\|f[\boldsymbol{x}(t_1)],\boldsymbol{\rho}\|$ is the vector norm of the state matrix evaluated at time t_1, and $\boldsymbol{V}_1$ is the first column vector of $\mathbf{V}$. This approximation holds true at any large times $t\gg\tau$, when the system is nonzero, and when the period of oscillation is sensitive to at least one parameter [75.156].

$$\mathbf{S}^{\tau}\approx\pm\frac{\sigma_1\tau}{\|f[\boldsymbol{x}(t_1)],\boldsymbol{\rho}\|t_1}\boldsymbol{V}_1 \qquad (75.6)$$

Amplitude sensitivity $\mathbf{S}^{\wedge}$ describes how maximum state values vary due to independent parametric perturbations. As discussed, cleaned-out sensitivity defines how parametric perturbations affect the shape of state trajectories at every time in the cycle; at peak concentration times this measure relates directly to the state's maximum concentrations. Thus, amplitude sensitivity values are calculated from shape sensitivity by evaluating the time-dependent measure (75.7) at peak concentrations times t_{peak}

$$\mathbf{S}^{\wedge} = \mathbf{S}^{\text{C}}(t_{\text{peak}}) \,. \tag{75.7}$$

75.6.2 Phase-Based Sensitivity Metrics

In cases involving oscillatory networks and often noisy state amplitude data, phase may be employed as a metric for model development and analysis. Standard (raw) phase and decoupled (corrected) phase are among the set of numerical performance measures introduced in [75.146]. Radian-based phase angles $\theta(t,\rho)$ are extracted from the system's limit cycle (Fig. 75.9a) using the cosine rule [75.158]. Resulting phase dynamics reflect the oscillator's real-time position, or concentration (75.8), with respect to a static reference $\boldsymbol{r}$

$$\cos[\theta(t,\boldsymbol{\rho})] \approx \pm \frac{\boldsymbol{x}(t,\rho)^{\top}\boldsymbol{r}}{\|\boldsymbol{x}(t,\boldsymbol{\rho})\|\,\|\boldsymbol{r}\|} \,. \tag{75.8}$$

Phase measures are recorded under varying parameter sets, $\theta(t,\tilde{\boldsymbol{\rho}})$, where $\tilde{\boldsymbol{\rho}}$ indicates measurements with respect to a perturbation of magnitude δ affecting a single parameter ρ_j. This perturbation changes the nominal parameter vector from $\boldsymbol{\rho}$ to a perturbed parameter vector ρ_j

$$\tilde{\boldsymbol{\rho}} = \boldsymbol{\rho} + \delta \boldsymbol{e}_j \,, \quad \forall j \in [1,n] \,. \tag{75.9}$$

The collected phase trajectories capture the oscillator's position and map them onto nominal time (Fig. 75.9b). If the perturbation strength and length are the same, the information contained in these trajectories is analogous to that contained in phase transition curves [75.159]. Direct evaluation of phase trajectories (Fig. 75.9b) yields two types of sensitivity measures: period and phase, because the change in period (or period sensitivity) is merely an accumulation in the change in phase (or phase sensitivity) evaluated over an entire cycle. In the case of period sensitivity, phase trajectories are evaluated at a $2\pi L$-radian interval, where the integer interval L is chosen to balance the numerical error with computational expense. The difference between the perturbed $2\pi L$-radian crossing time $\tilde{k}$ and the nominal $2\pi L$-radian crossing time k yields the system's periodic performance. A normalized time difference between perturbed and nominal phase trajectories defines the system's period sensitivity, $\mathbf{S}^{\theta_\tau}$ (75.10): a series of measurements denoting the quantitative change in period with respect to a change in the j-th parameter

$$S_j^{\theta_\tau} = \frac{1}{L}\frac{\tilde{k}-k}{\delta\rho_j}\bigg|_{\theta(k,\boldsymbol{\rho})=\theta(\tilde{k},\tilde{\boldsymbol{\rho}})=2\pi L} \,, \\ \forall j \in [1,n] \,, \; L \in [1,\infty) \,. \tag{75.10}$$

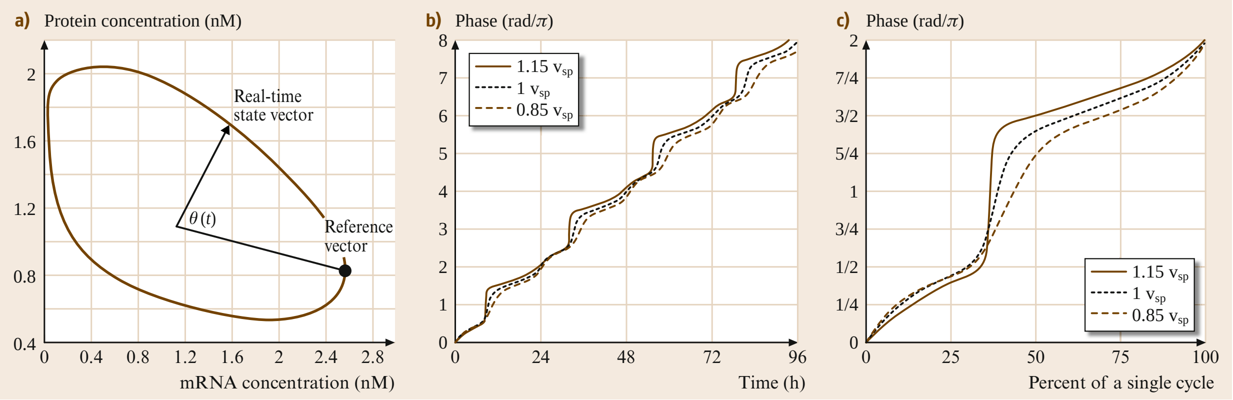


Fig. 75.9a–c Time-dependent phase dynamics. **(a)** Real-time phase dynamics captured in a 2-D limit cycle. Phase is the radian-based measure $\theta(t,\boldsymbol{\rho})$ that describes the angular relationship between the state vector $x(t,\boldsymbol{\rho})$ and some predetermined reference $\boldsymbol{r}$. Phase measures are recorded as a function of time under various parameter sets. **(b)** Coupling of period and phase as trajectories diverge in time. **(c)** Decoupled measure of phase behavior as circadian phase dynamics are normalized with respect to their perturbation-induced periods (after [75.146, 157] by permission of Oxford University Press)

In the case of strict phase sensitivity, one can evaluate phase trajectories at specific times $t = t_k$. The radian phase difference between perturbed and nominal trajectories describes the raw phase sensitivity, $\mathbf{S}^\theta$ (75.11): a series of measures reflecting the induced change in phase with respect to a change in the j-th parameter t_k-hours after the perturbation

$$S_j^\theta(t_k) = \left.\frac{\theta(t,\tilde{\boldsymbol{\rho}}) - \theta(t,\boldsymbol{\rho})}{\delta\rho_j}\right|_{t=t_k} , \quad \forall j \in [1,n] . \qquad (75.11)$$

Just as state sensitivity diverges over time, phase sensitivity grows unbounded due to the nonuniform expansion of a periodic system. To correct for the integrated response of perturbation effects (in this case, the coupling of period and phase), each phase trajectory is normalized with respect to the period of the system after parametric perturbation $\tilde{\tau}$: dividing each time series by $\tilde{\tau}$ decouples the system's phase from its period. As a result, normalized datasets begin and end at the same relative time points (0 and 100% of their respective cy-

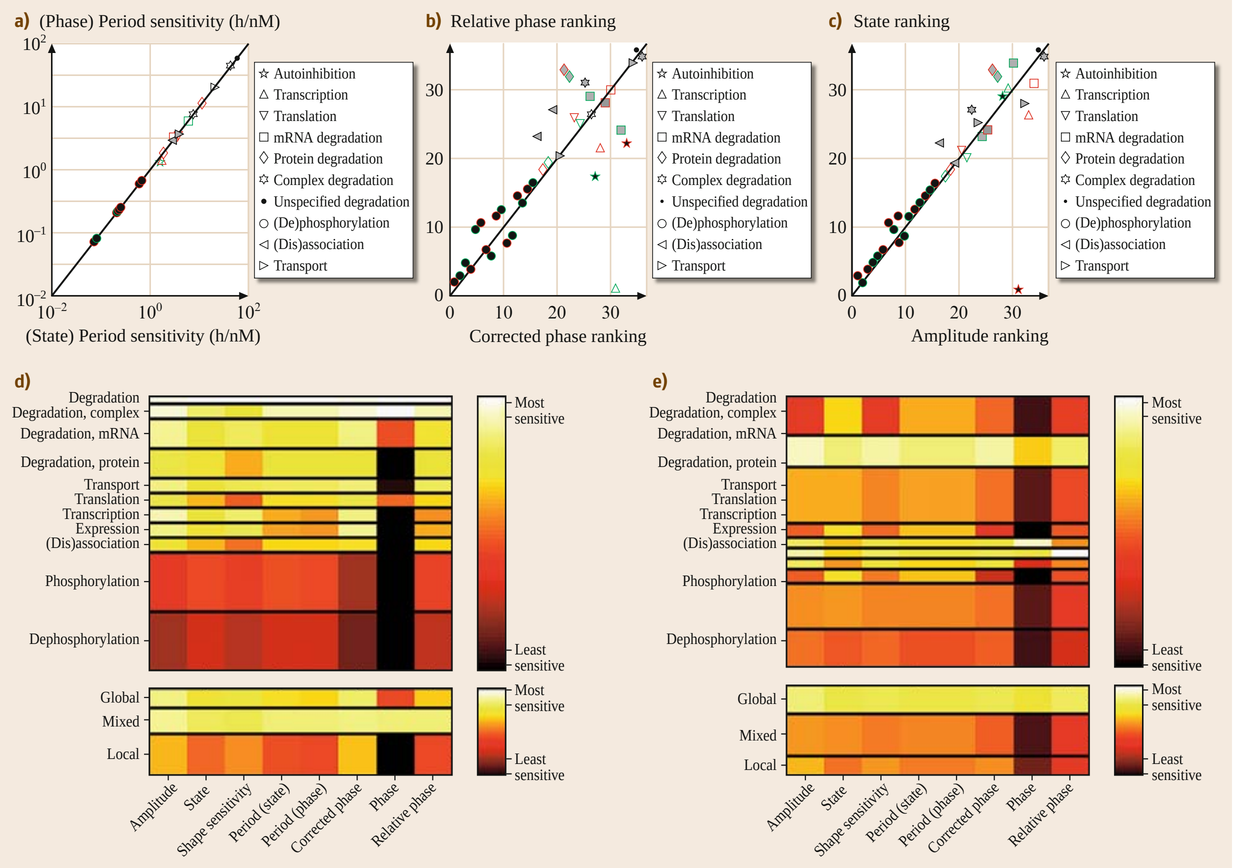

Fig. 75.10a–e Metric evaluation. **(a–c)** Parametric sensitivity metrics ordered from least to greatest absolute value for the Drosophila model: **(a)** state-based and phase-based period sensitivity, **(b)** corrected phase (decoupled angular phase trajectories) and relative phase (time interval between peak per mRNA and nuclear PER/TIM protein concentrations) sensitivity ranks and **(c)** amplitude-based and state-based metrics. Spearman rank correlation coefficients for these pairs of metrics are 1.00, 0.64 and 0.85, respectively. Legends describe the parameters' particular biological processes as the shading of each data point describes their type: global (*open*), mixed (*gray*) and local (*black*) parameters. Data points outlined in *red* reflect *per* gene dynamics, and those in *green* reflect *tim* gene dynamics. **(d,e)**, Color-coded average sensitivities (values are scaled between 10^{-4} and 1) among parameter function (*upper subplots*) and parameter type (*lower subplots*) for each metric in the fly **(d)** and the mammalian **(e)** model. See the supplementary material for alternate correlation diagrams and ranking plots (after [75.146, 157] by permission of Oxford Univ. Press)

cles). These modified datasets allow for a comparison between nominal and perturbed phase at every point in the cycle (Fig. 75.9c). This corrected phase sensitivity assumes a linear scaling of raw phase measures resulting in a time-dependent performance quantity that identifies specific points of the cycle most susceptible to uncertainty (75.12)

$$S_j^{\widehat{\Theta}}(t_k)=\frac{\theta(t/\tilde{\tau},\tilde{\boldsymbol{\rho}})-\theta(t/\tau,\boldsymbol{\rho})}{\delta\rho_j}\,,\quad \forall j\in[1,n]\,. \tag{75.12}$$

Phase-based period, phase, and corrected phase sensitivity analysis examine the biological network relative to a static reference. In some cases, a relative analysis that studies relationships within the perturbed network may be more useful. The timing effects relating transcription, translation, phosphorylation, and transport are governed by global cellular processes. Variation of these specific time intervals as a result of parameter manipulation indicates a degree of sensitivity. Relative sensitivity $\mathbf{S}^{\phi}$ investigates the time interval relating the hour-difference between the occurrence of particular events; for instance, the time interval between peak mRNA concentrations and their corresponding protein concentrations. This time interval $\phi[\mathbf{x}(t),\boldsymbol{\rho}]$, is a function of the system's state and parameter vectors. It explores how a system's individual components change relative to one another due to parametric perturbation (75.13)

$$S_j^{\phi}=\frac{\phi[\mathbf{x}(t),\tilde{\boldsymbol{\rho}}]-\phi[\mathbf{x}(t),\boldsymbol{\rho}]}{\delta\rho_j}\,,\quad \forall j\in[1,n]\,. \tag{75.13}$$

75.6.3 Global Versus Local Parameters

The investigated performance metrics depict classes of sensitivity that associate with parameter function, providing a certain conservation of robustness for specific biochemical processes. A similar sensitivity distribution was found when parameters were separated into three types: global, mixed, and local [75.15]. Global parameters are involved in core cellular reactions nonspecific to the circadian rhythm; they encompass properties consistent with the entirety of the cellular network. Local parameters are primarily attributed to the circadian system; their processes and/or elements are not shared with many other cellular circuits. Global parameters include transcription rates, various mRNA and protein degradation rates, and translation rates.

Figure 75.10a–c depict phase-based and state-based period sensitivities, relative and corrected phase sensitivities, and amplitude and state sensitivities. Global parameters were consistently found in the first (upper right) quadrants of these plots. Local parameters, including protein phosphorylation and dephosphorylation, were consistently in the lower left (less sensitive) corners. Figure 75.10d and e (lower subplots) emphasize this conservation of sensitivity apparent in both models by assigning a color reflective of the average sensitivity ranking within each parameter type.

The results demonstrated that every defined performance metric was more sensitive to perturbations involving global and mixed parameters than it was to perturbations involving local parameters. Grouping parametric sensitivity based on parameter type provided a more consistent and distinct distribution of sensitivity measures among various metrics than the grouping of sensitivity by function. This outcome agreed with a previous study suggesting that circadian performance is greatly affected by changes in global parameters and less susceptible to changes in local parameters [75.13, 15].

75.7 Bio-inspired Control and Design

Biological networks offer a number of opportunities for inspired design of engineering networks. Aside from the overlapping computational toolkit (e.g., simulation methods for high dimensional, stochastic, stiff, multiscale systems), there are numerous behaviors in biological networks that offer promise for improved communications and sensors networks. Given the space constraints, we highlight only two of them here, but refer the reader to the thorough NRC report on network science for additional details [75.160].

Using control engineering parlance, one may refer to the elements that influence or entrain the circadian oscillator (*zeitgeber*: time giver) as manipulations, and the elements that exhibit quantifiable circadian rhythms as measurements. The use of this terminology is reflective of the spirit in looking for ways to influence rhythms to fine tune physiological performance. Continuing the control analogy, the open-loop characteristics (i. e., with no intervention) of the typical human are to adjust at a rate of approximately 60–90 min of phase per day [75.161]. In other words, jet lag accommodation occurs at a rate of approximately 2–3 days for a 3 h time zone change. Westward travel is slightly easier, as the natural free-running human circadian clock (i. e., in absence of light) has a period of approximately 25 h. From a control perspective, the two important attributes of the resetting response characteristics are phase shift (captured by the phase response curve), and the associated transient, which we define via the transient response curve.

Sensitivity analysis can be used to develop insight on the parts of a network that are most sensitive and, consequently, the most susceptible to intervention such as the targeting of a drug. However, a typical application will require a temporal forcing of a node (or nodes) in a network to elicit an optimal response. In recent work, model predictive control (MPC) algorithms have been employed to generate the optimal forcing protocol that will reset the circadian clock from a condition of phase offset (i. e., jet lag) [75.157, 162]. Through parametric state sensitivity analysis, key driving mechanisms for optimal manipulation of the large complex circadian network were identified. Importantly, the use of nonphotic control inputs outperforms light-based phase resetting dynamics. Aside from targeting individual parameters as control inputs, Fisher information matrix based parametric sensitivity analyses identified combinations of parameters for control (i. e., vector strategies). The derived MPC algorithm is found to be robust to model mismatch and outperforms the open-loop 24 h sun cycle based phase recovery strategy by nearly threefold.

75.8 Emerging Trends

Systems biology has an exciting future. Opportunities for research exist in the areas of network identification, constraints and optimality, stochastic systems, and robustness [75.4], as well as synthetic approaches to network reconstruction:

1. Knowledge of biological systems is incomplete, and codification of the interactions among network components, interactions, and properties requires continued elaboration. This systems identification problem can be approached via empirical, approximative, and mechanistic methods.
2. An understanding of biological systems may proceed from an appreciation of constraints, which can be divided into three classes: (1) Functional constraints exist because biological systems perform specified functions arising from a finite set of components. Since biological systems evolve to a performance metric, it is sensible to presume optimality. This leads to a smaller design space with highly structured, but rarely composed, reliably networks. (2) Analysis of experimental data can provide data on the possible arrangements for network structure. (3) The laws of physics and chemistry, must, of course, be observed.
3. Developments in systems biology will continue to depend upon algorithmic innovations to approach stochasticity, particularly for distributed models.
4. There exist intrinsic scaling problems with those engineering methods that provide a formal framework for robustness analysis. For large, complex, nonlinear systems, the methods are conservative and computational tractability is questionable. Consequently, the scalability of robustness analysis methodologies provides interesting future challenges.

One promising application of a systems approach to biology lies in healthcare [75.163]. Unlike today's medicine, with its emphasis on therapies for existing disease, tomorrow's medicine will predict and prevent illness. Multiparameter diagnostics will be used routinely to assess health status. Network science will be used to ascertain drug targets, leading to true preventive medicine.

The emerging bio-inspired automation and automatic control mechanisms, techniques and models will continue to offer rich sources of innovation. We will continue to search how the benefits of systems biology knowledge in living organisms can help us solve complex, critical problems in increasingly interrelated systems and service infrastructures.

76. Automation and Control in Biomedical Systems

Robert S. Parker

Biomedical systems are a complex collection of case studies where the principles of automation and control theory are seeing increased application. This growing interest has a twofold motivation: the need for advanced automation and treatment design tools for use in medical practice and the challenges inherent to biomedical systems and clinical deployment of technology. This chapter provides an overview of the automation, control, and optimization tools used in the biomedical arena. While the scope of potential applications is vast, examples of biomedical treatment design systems for cancer and insulin-dependent diabetes are discussed. The chapter concludes by scratching the surface of emerging areas in need of translated or novel systems and automation tools.

76.1 Background and Introduction

76.1.1 Scope

Automation is ubiquitous in society today. Air conditioners and thermostats keep the house cool; cruise control maintains speed without driver intervention on the road. Both of these examples demonstrate the efficiency of automating processes and taking advantage of advanced control algorithms in doing so (the switching on and off of the air conditioner and the degree of depression of the gas pedal are both handled by mathematical algorithms). With advancements in engineering, miniaturization, and computational capability, it becomes possible to deploy automation and control tools in the medical arena. A common example of automation in medicine is the pacemaker, with a quarter-million per year implanted around the world [76.1]. Far from the simple pacing instrument of 1932 [76.2], today's devices include diagnostic algorithms for real-time analysis, adaptive response (control), and programmability [76.1]. Robotics is a common tool used in medical science, and due to its wide treatment elsewhere, this topic is consciously excluded from the present chapter (the interested reader is referred to [76.3] from the *Handbook of Industrial Robotics*). This chapter will explore the use of mathematical models of the body (in a variety of styles, see Sect. 76.2 for more detail) as well as tools from optimization and dynamic control theory in the automation of medical treatment decisions and the deployment of treatment. While modeling the body is certainly not a new concept – *Teorell* discussed the use of mathematical modeling in drug distribution as early as 1937 [76.4, 5] – the ability to deploy these models is a relatively recent event given the continuing advancement of computational power.

Medical practice, in a broad sense, is a discipline grounded in finding feasible solutions to complex biosystems problems. Typically, clinicians are presented with a set of symptoms from which they must diagnose and treat a disease state. Treatments induce response, and when drugs are administered, the dose amount and schedule (timing of doses) elicit a variety of measurable outcomes such as drug pharmacokinetics (PK, drug concentration versus time) and pharmacodynamics (PD, disease response and toxicity). Schematically, this is the unshaded component shown in Fig. 76.1. The shaded region characterizes a model-based control system that:

1. Compares the measurable responses to treatment to a desired clinical response
2. Employs a control algorithm and mathematical model of the patient to calculate an optimal treatment
3. Deploys that treatment by adjusting dose and schedule of administration

Typically, this last phase would be a recommendation to a clinician who would be responsible for the ultimate go/no-go decision of implementing the algorithm-recommended treatment. The challenge in designing such automation systems is the complexity of the underlying model of the patient and its incorporation within a rigorous mathematical framework for optimizing or controlling the treatment outcome.

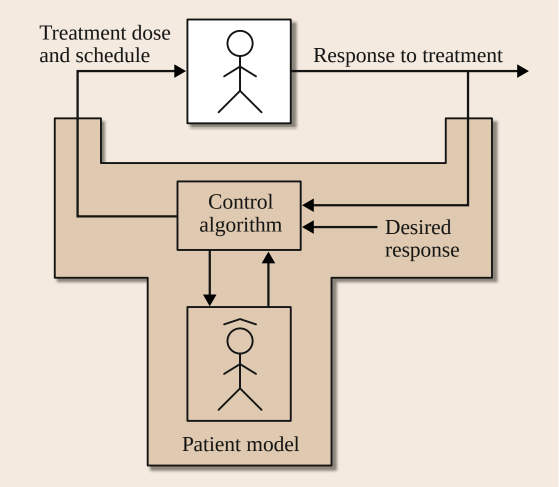

Fig. 76.1 Schematic of drug treatment. *Unshaded*: open-loop, *shaded*: automated model-based decision support or control system for treatment design and/or implementation

When translating systems tools to the clinical arena, it is critical to work closely with clinicians. Unlike a distillation column, where automation tools can be implemented as long as their performance is superior to existing technology, the most likely early implementation of automation tools in the biomedical arena is as decision support (a semi-closed-loop formulation). The charge of the clinician to *do no harm* and the critical issue of malpractice, with its corresponding financial and legal ramifications, are too significant to allow an automated system to operate independently without oversight. Even a single failure resulting in the death of a patient could halt the development and deployment of an automated medical device. Hence, extensive clinical trials demonstrating safety of patients (phase I trials), efficacy of the automated tool or decision support system (phase II), and ultimately performance superiority to current standards of practice (phase III/IV trials) will be required before an automated device can be deployed with confidence in the biomedical arena.

The remainder of this section will establish challenges to automation in biomedical systems. The first set are data issues, including quantity available, quality, resolution, and consistency and frequency of collection (for use in dynamic modeling). The differences between preclinical and clinical data are discussed, and the concept of patient tailoring (including interpatient variability and treatment individualization) is introduced. The chapter continues in Sect. 76.2 with the tools used in biosystems automation and control. Two case study areas are discussed in detail in Sect. 76.3, and a small selection of directions of future research are summarized in Sect. 76.4.

76.1.2 Data Quantity and Quality

The amount of experimental biological data in the literature is vast. However, the size scale of the data is equally large (spanning nanometers to meters and beyond). The dynamic character of the data varies as well, including static *baseline* measurements, point measurements of biological changes (the usual case in *-omics* data), and dynamic PK profiles. A further complication captured in data sets such as those from DNA microarrays is the complexity of the interaction between the various cellular processes, which is simultaneously

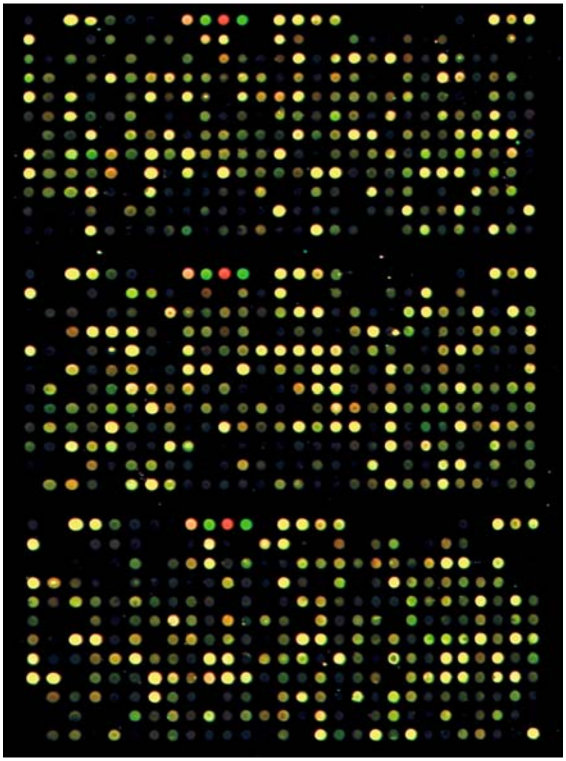

Fig. 76.2 Expression response of MCF breast cancer cells treated with vitamin D (figure originally published in [76.6])

a complication in the use of modeling and automation tools and a challenge to those interested in building new tools. It is at this crossroads of biology and systems engineering that computational models and automation tools can make a significant contribution by unifying the collection of disparate data across multiple scales and time points.

Facilitating the collection of this interacting dynamic data are advances in measurement technology that provide higher-resolution information of the biological processes taking place. Microarray technology has provided a more detailed picture of DNA and RNA responses to external stimuli, and these tools may eventually provide a fully dynamic profile of specific up- and downregulation events in response to drug treatment. The data available from a microarray study at present, however, do not provide such a picture. The measurements are often distributed in time, with significant nonmeasurement periods, so the dynamics of a particular challenge may or may not be fully captured. Furthermore, the ability to quantitate at high precision with a microarray is limited by the sensing technology; semiquantitative and directional information is available from the colorimetric technique, but exact counts of DNA or RNA are unavailable (Fig. 76.2). Tissue concentrations of agents are measured using high-performance liquid chromatography (HPLC) as the *gold standard*; however, liquid-chromatography mass spectroscopy (LC/MS) has higher resolution (the ability to measure fewer ng/ml) and lower sample volume requirements. Hence, PK data may be more accurate in the future, thereby leading to higher-quality models and possibly to better informed treatment decisions. A potential drawback of this new technology is the need to repeat previous studies with the new analysis device. This may lead to conflicting outcomes between studies as superior measurements are analyzed, and model refinement should be an expected and ongoing process. Given these factors, modelers and algorithm developers must carefully evaluate the data sets they employ, and the ongoing generation of new data, to be sure that the treatment decisions recommended by automated tools are of the highest possible quality and provide the greatest potential benefit to the patient.

76.1.3 Preclinical Versus Clinical Study Data

Animal studies are a required precursor to human trials for testing novel drugs. These studies are primarily toxicologic – the objective is to establish toxicities associated with drug administration and to evaluate the various routes of administration (oral, intravenous (IV), etc.). Pharmacokinetic studies are often required by the US Food and Drug Administration (FDA) [76.7]. The search for tissue toxicities leads to detailed (potentially dynamic) concentration versus time data sets from animals for compounds of potential clinical interest. The outcome of these studies is often a maximum tolerated dose (MTD) in a variety of species, and the dose for first trials in humans is established from the MTD in the most sensitive species. A useful side-effect of these studies, from an automation perspective, is the value of these data sets in modeling dynamic biological phenomena at scales that one cannot achieve in humans (e.g., tissue drug concentration versus time via destructive analyses such as HPLC or LC/MS).

Animals are not people, however. A critical shortcoming of model-based automation and control for the biosystems field is that most of the high-resolution (temporal or spatial) in vivo data comes from animal studies. Hence, detailed animal models of pharmacokinetic and pharmacodynamic behavior can be constructed [76.8–10], but the scale-up of these models to humans remains open (Sect. 76.4.2). In contrast, pharmacokinetic and pharmacodynamic models collected in clinical trials are often macroscopic in nature. Measurements are often easy to collect and analyze, such as urine measurements of function or disease state (e.g., creatinine clearance or glucose in the urine), drug concentrations in the bloodstream, or circulating markers of effect (e.g., cholesterol levels in the blood). Furthermore, measurements from a single patient are often not a full time course but a small number of samples (1–3) that provide the clinically necessary information but may not provide sufficient data to inform a model of the individual patient. Depending on the resolution and prediction required from the model, as well as its intended use, a variety of tools may be employed in model synthesis and deployment at the animal and human scales. These are outlined in the next section.

76.2 Theory and Tools

This section will introduce some of the tools often employed in the solution of biomedical modeling and control problems. A summary can be found in Table 76.1, which provides the section where a technique can be found, the name of the technique(s) discussed therein, and one or two strengths and weaknesses of the various approaches. While this is certainly not a canonical summary of tools employed in the automation of biomedical problems, this section provides a jumping-off point for further reading on the tools and techniques of biomedical control.

76.2.1 Parameter Estimation

In the development of mathematical models, there is a need to estimate parameters. A concern in this arena is the a priori identifiability of such models. Phrased differently: are the parameters of a given model *structurally identifiable* from the available input–output (measurement) data? A number of recent studies of biomedically relevant systems explore tools and methods for evaluating model identifiability [76.11–15]. *Audoly* et al. [76.11] examine the identifiability of linear models, which has direct mapping to the popular compartmental models used in pharmacokinetic analysis (Sect. 76.2.2). Physiological structures are the focus of *Yates* [76.13], who examines the global identifiability of the model with restriction to local identifiability in the worst case. In a nonlinear context, *Bellu* et al. [76.15] provide differential algebra for identifiability of systems (DAISY) software to evaluate the identifiability of nonlinear systems in polynomial or rational form (a limitation of the differential algebra tool used in the analysis). At a higher level of resolution, intracellular networks are of particular interest in systems biology, metabolomics, etc. The amount of information that is measurable from these systems is generally small with respect to the parameters. *Van Riel* and *Sontag* [76.14] explore methods of modeling these systems using fictitious dependent inputs to represent unidentifiable model structures.

Given an identifiable model, parameter values need to be estimated with confidence. Two common objectives for parameter estimation include nonlinear least squares and maximum likelihood. The nonlinear least-squares technique can be represented as [76.16]

$$\min_{\boldsymbol{p}}\ J(\boldsymbol{p}) = \sum_{i=1}^{N} \chi_i [y_{\mathrm{m}}(i) - \hat{y}(i,\boldsymbol{p})]^2 \,. \tag{76.1}$$

The measured data at observation i is given by $y_{\mathrm{m}}(i)$, the model prediction at the same observation, which depends on parameters $\boldsymbol{p}$, is represented by $\hat{y}(i,\boldsymbol{p})$, and the observation-dependent weights are given by χ_i. In the unweighted case χ_i reduces to an appropriately sized identity matrix. Alternatively, weighting by $\chi_i = 1/\sigma_i^2$ can reduce sensitivity to variability in the measurement, where σ_i is the standard deviation of the measurement data at observation i. Standard tools for this optimization using linear or nonlinear models are available in MATLAB [76.17]. An alternative objective is maximum-likelihood estimation (MLE), a statistical approach to parameter estimation. Here, the conditional probability that the residuals are generated by a model having the estimated parameter vector is maximized. The likelihood function is written as [76.16]

$$L(\boldsymbol{p}) = \prod_{i=1}^{N} \frac{1}{\sigma_i\sqrt{2\pi}} \left[\frac{-1}{2}\left(\frac{y_{\mathrm{m}}(i)-\hat{y}(i,\boldsymbol{p})}{\sigma_i}\right)^2\right] . \tag{76.2}$$

The objective is to maximize the likelihood that the data results from the model (as parameterized by the vector $\boldsymbol{p}$). Assumptions in using maximum likelihood include: (i) uncorrelated residuals and (ii) residuals are

Table 76.1 Summary of theory and tools by Section, topic(s), and advantages/disadvantages of the various methods

Section	Topic(s)	Pros (+) and cons (–)
76.2.1	A priori identifiability	+ Highlights parameter estimation concerns based on available data – Theoretically and computationally challenging
	(Weighted) least squares	+ Straightforward application, many tools available – Weighting of points is subjective
	Maximum likelihood	+ Robust and commonly employed – Based on assumed error structure/distribution
76.2.2	Compartmental PK	+ Compact models, generally identifiable – No relationship to mechanism or physiology
	Population PK	+ Incorporates intra-/interpatient variability in model (when justified by available data) – Not straightforward to tailor to an individual – Patient and data intensive
76.2.3	Physiological PK	+ Incorporates patient physiology explicitly – Measurements of individual tissues are difficult to collect (limited to animal studies) – Large number of equations makes parameter estimation computationally challenging
76.2.4	Biochemical networks	+ May provide high-resolution mechanistic detail – May be difficult to resolve causality (cause versus effect) – Semiquantitative (colorimetric)
76.2.5	Optimal control	+ Solves constrained dynamic optimization problem – Formulation (two-point boundary-value problem, continuous controls) must be reasonable for solution of corresponding biomedical problem
	Model predictive control	+ Robust to mismatch between actual patient/process and mathematical model + Solves constrained dynamic optimization problem – Suboptimal (relaxed) solution of problem – Mathematical analysis of stability and performance is theoretically challenging

zero mean and normally distributed with variance σ_i^2. While these may not be rigorously true of biomedical data sets, MLE has been shown to work well with biomedical data, and packages are available that use MLE for estimation [76.18, 19]. These packages also return parameter information in the form of a confidence interval or coefficient of variation. Large values indicate poor parameter accuracy, and hence possible structural parameter identifiability issues [76.20] or violations of the assumptions above as parameters may not be Gaussian distributed in the modeling of multiple individuals.

76.2.2 Pharmacokinetics

PK is the study of drug administration to, distribution in, and clearance from the body [76.4,5]. To capture the dynamics observed after drug dosing, compartmental models are often employed (Fig. 76.3). The administered dose is given by $D(t)$. Individual compartments are modeled as drug masses (x_1 and x_2), with correction to concentration in the output equation (via division by volume V). Clearance of the drug is from the central compartment (rate k_{cl}). Additional dynamic character is included by adding compartments and intercompartment transfer rates (k_{ij} from compartment i to compartment j). A two-compartment model can be represented mathematically as

$$\frac{\mathrm{d}x_1(t)}{\mathrm{d}t} = -k_{\mathrm{cl}}x_1(t) - k_{12}x_1(t) + k_{21}x_2(t) + D(t)\,, \tag{76.3}$$

$$\frac{\mathrm{d}x_2(t)}{\mathrm{d}t} = k_{12}x_1(t) - k_{21}x_2(t)\,, \tag{76.4}$$

$$y(t) = \frac{x_1(t)}{V}\,. \tag{76.5}$$

The output(s) of the model corresponds to measurable concentrations of drug, as given by $y(t)$. Additional blocks can be added, as necessary, to capture observed plasma dynamics related to dosing (for drugs not delivered intravenously) and/or absorption. The resulting model is an empirical description of patient drug concentration as a function of time after administration. These model structures are commonly employed using available PK modeling tools such as ADAPT II [76.18], and the FDA requires some pharmacokinetic information for most new chemotherapeutics [76.7]. Parameters in the model can be estimated from individual patient data, when detailed pharmacokinetic measurements are available. More often, models of this form are constructed from animal studies where multiple animals (e.g., mice or rats) are euthanized at each measured time point. The mean and standard deviation of measured drug concentrations are used as the data to which a single model is fit. Low-order deterministic models may not capture the observed drug concentration measurements for a variety of reasons, including nonlinearity, higher-order dynamics, and interindividual variability.

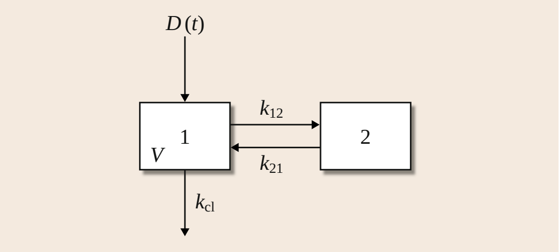

Fig. 76.3 Two-compartment mamillary model used in pharmacokinetic analysis. Plasma dynamics are captured by the central compartment (block 1) in Eq. (76.3)

To address interindividual variability and data sparsity, population models are often developed [76.16, 21, 22]. In this case, a stochastic approach to model parameterization is employed, where parameters are composed [76.21] as

$$\boldsymbol{p}_i = \theta_\mu + \eta_i^{\boldsymbol{p}} + \theta_{\mathrm{c}}C_i\,. \tag{76.6}$$

Parameters ($\boldsymbol{p}_i$) for patient i are a function of the population mean value of the parameter θ_μ, interindividual variability in the parameter $\eta_i^{\boldsymbol{p}}$, and any known correlative effects C_i scaled by their population mean correlation θ_{c}. These parameter formulations are then included in model structures akin to those in (76.3–76.5), as replacements for the k_{ij} and $k_{\mathrm{c}i}$ parameters, for example. Variances on the measurement noise (added to (76.5)) and interpatient variability η_i are specified as part of the estimation. With this approach, it is possible to use a small number of output measurements from a large number of individuals to characterize both the underlying model structure (through the observed dynamics) and the population variability (through the need for η and θ_{c} or C_i to describe individual responses). Software tools are available for constructing these models (including NONMEM [76.22] and SPK [76.23]). A population model, once constructed, is representative of the population response to a drug dose. Furthermore, it can provide a characterization of both validated variabilities (as a function of body weight, gender, race, liver or kidney performance status, etc.) and the distribution of responses expected after dosing a group of patients with the drug. However, it is not designed to be predictive in the single-patient case; here it may be of more use to couple the variabilities established in the population model with the ability to tailor an individual PK model.

76.2.3 Modeling Physiology

The potential of detailed physiological models was recognized by *Teorell* when he began studying pharmacokinetics [76.4, 5], but calculational limitations made physiological modeling of drug PK intractable in 1937. With today's desktop computational power, simulating physiological models of drug administration and distribution is straightforward. A physiologically-based model for a cancer chemotherapy application is shown in Fig. 76.4. Each block in a physiologically-based model represents an ordinary differential equation that characterizes concentration in a particular tissue or fluid, with the volume of the compartment corresponding to the physiological volume into which the compound distributes. Where necessary, subcompartments can be added to modify tissue dynamic response, and these are often denoted as vascular (blood space) and extravascular (interstitial space) compartments (models may also include intracellular or tissue binding spaces as well [76.8, 24]). Transfer between vascular and extravascular space can be via gradient-based diffusion or active transport, and may be uni- or bidirectional. Unidirectional arrows between tissue compartments denote the flow of blood; the bidirectional arrow pairs between red blood cells (RBCs) and the plasma compartments represent equilibration (transport is often fast in RBCs, such that they are often represented algebraically rather than differentially). Metabolic elimination and clearance are shown as unconnected arrows exiting particular (sub)compartments (e.g., the arrow out of liver extravascular space), and infusion into the system can be properly placed in a physiological sense, e.g., the IV dose administered to the venous blood compartment. Advantages of this approach include the accuracy of the tissue connectivity and the availability of mean values for the flow and volume parameters [76.25]. Furthermore, knowledge of the metabolic pathway of drug clearance (e.g., liver metabolism or kidney excretion) can be included in the physiologically correct location. This structure changes the identification burden to that of metabolic rates and intratissue transport (plasma ↔ interstitial fluid ↔ cell) and dynamics. Resolution of these effects can be challenging (when feasible) as the necessary information (e.g., arterio–venous differences in drug concentration) for identification is not typically available from in vivo measurements. The result is that tissues are often assumed to be well mixed if they are highly perfused (e.g., kidney and liver), and only tissues where significant transport resistances are involved are modeled using more detailed intratissue dynamics (and then often using a compartmental approach).

The utility of these structures is of more potential benefit when evaluating pharmacodynamic effects. Unlike the compartmental or population models described above, the physiological model also allows the effects of the drug to be properly assigned to their physiological sites of action. These outcomes can be positive (e.g., antitumor activity related to tumor concentration, not plasma concentration, of an antineoplastic) or negative (e.g., toxic side-effects of a drug affecting liver performance status). This is a significant advantage in the use of in vitro information for the purposes of in vivo modeling, as the concentration at the site of action (effect or toxicity) is more accurately represented by a physiological model than the plasma concentration estimate of a compartmental model.

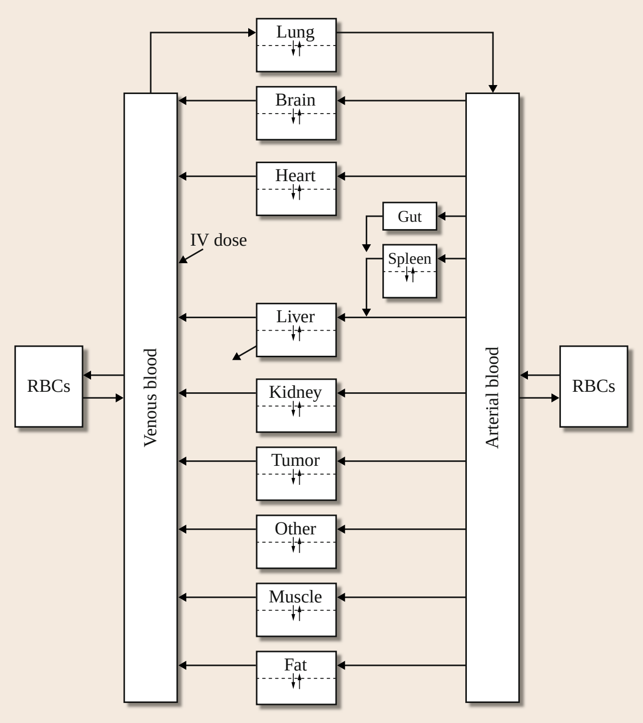

Fig. 76.4 Block structure schematic of a physiological model of drug distribution

76.2.4 Biochemical Networks

Phenotype is related to genotype at some level, meaning that macroscopic observables such as physiology, PK, etc., are driven by biological networks at a variety of scales. The field of systems biology is focused on developing a systems-level description of biology by studying the dynamics of cellular and organ function, rather than the traditional drill-down study of increasingly highly resolved portions of a cell [76.26]. In order to rigorously integrate the complex behaviors taking place at the genetic level with the macroscopic (whole-organism) response, and to ground these hypotheses in experimental data, requires a computational model [76.27].

Due to the scales spanned in network analysis (from the gene regulatory [76.28] to the metabolic [76.29]), it is infeasible in this space to review the plethora of tools employed. Ordinary differential equations, due to their simplicity, are popular, and compartmental approaches (such as those in Sect. 76.2.2) are also used to simplify the model structures. The systems biology markup language (SBML) is one tool for representing biochemical networks, both qualitative and quantitative [76.30]. A review of SBML, along with two other data representation standards (PSI MI (Proteomics Standards Initiative Molecular Interaction) and BioPAX), can be found in [76.31]. The strengths of these packages can be seen in the complexity of the models that are generated, and can be simulated, as a result of complex network modeling (see [76.29] and models at www.systems-biology.org and www.biopax.org).

76.2.5 Model-Based Control and Optimization

A commonly employed tool in model-based treatment design for biomedical systems is optimal control. Mathematically, optimal control problems can be formulated as follows [76.32]

$$\min_{u(t)} \; J(y(t), u(t), r(t)) \,, \tag{76.7}$$

$$\text{subject to: } \dot{\boldsymbol{x}} = f(\boldsymbol{x}(t), u(t), \boldsymbol{p}) \,, \tag{76.8}$$

$$y(t) = h(\boldsymbol{x}(t), u(t), \boldsymbol{p}) \,, \tag{76.9}$$

$$u_{\text{min}} \leq u(t) \leq u_{\text{max}} \,, \tag{76.10}$$

$$y(t_{\text{f}}) = y_{\text{fin}} \,. \tag{76.11}$$

The objective function (76.7) often takes the form of a least-squares deviation of $y(t)$ from some desired trajectory $r(t)$, and the decision variable is the $u(t)$ profile over $0 \leq t \leq t_{\text{f}}$; for example, in the diabetes example introduced later in this chapter, the measured variable would be plasma glucose concentration ($y(t)$), $r(t)$ would be the desired glucose concentration (e.g., 90 mg/dl), and $u(t)$ would be the insulin delivery profile (or delivery rate) from the present time t to $t+t_{\text{f}}$. Feasible system trajectories are governed by the dynamics of the model (states $\boldsymbol{x}(t)$, parameters $\boldsymbol{p}$), and these are incorporated as constraints (76.8) and (76.9). Continuing the diabetes example, the states characterize the patient; in a physiological model context, these states would be the glucose and insulin concentrations in the various physiological tissues (not all of which are measurable). Constraints on the input magnitude can be enforced, as in (76.10); other input constraints can also be included, though they are not explicitly described here. Finally, a desired final value for the controlled variable $y(t_{\text{f}})$ is included. The identification of a feasible treatment, an input sequence that drives $y(0)$ to $y(t_{\text{f}})$, involves the solution of a constrained two-point boundary-value problem. Control vector parameterization [76.33] is a common method of computer implementation, where the time axis is discretized into k equal-length steps, and the series of input levels over each of the steps become the decision variables of the optimization problem. The resulting input profile generally has a characteristic bang–bang shape, switching from *full on* to *full off* at one or more points along the time axis. The strength of optimal control is the ability to solve nonlinear control problems in the presence of input constraints. A key shortcoming is the formulation of optimal control versus the practice of medicine. The former specifies an endpoint constraint and has no mechanism for the inclusion of information that becomes available at intermediate time points. Clinical practice, on the other hand, does not generally have an a priori specified end time of treatment and routinely takes measurements of patient performance status and incorporates these into treatment decisions.

One way to take advantage of model-based control and optimization techniques while retaining the advantages of the optimal control formulation is to use receding horizon control, also referred to as model predictive control [76.34,35]. Receding horizon control is an open-loop optimization posed and solved for a sequence of input move changes at each time step; a typical model predictive control formulation may be posed as

$$\min_{\Delta u(k|k)} \; \|\boldsymbol{\Gamma}_y(\boldsymbol{r}(k+1|k) - \boldsymbol{y}(k+1|k))\|_2^2 + \|\boldsymbol{\Gamma}_u \Delta\boldsymbol{u}(k|k)\|_2^2 \tag{76.12}$$

$$\text{subject to: } \boldsymbol{x}(k+1|k) = f(\boldsymbol{x}(k|k), u(k|k), \boldsymbol{p}) \tag{76.13}$$

$$y(k|k) = h(\boldsymbol{x}(k|k), u(k|k), \boldsymbol{p}) \tag{76.14}$$

$$u_{\text{min}} \leq u(k|k) \leq u_{\text{max}} \tag{76.15}$$

$$|\Delta\boldsymbol{u}(k|k)| \leq u_{\text{rate}} \,. \tag{76.16}$$

Because the model is used to predict output responses at future times (up to N_{p} steps in the future), statistical notation is employed, where $\boldsymbol{y}(k+1|k)$ is the vector of N_{p} predicted outputs at time $k+1$ given information up to time k. The corresponding vector of desired output values is $\boldsymbol{r}(k+1|k)$, and the degrees of freedom are the N_{u} input moves $\Delta\boldsymbol{u}(k|k)$. The matrices $\boldsymbol{\Gamma}_y$ and $\boldsymbol{\Gamma}_u$

are weights to trade off tracking error (large $\boldsymbol{\Gamma}_y$) versus input move suppression (large $\boldsymbol{\Gamma}_u$). The underlying model dynamics of (76.13) and (76.14) can be continuous or discrete, as they are simulated at each time step, but the output values employed in the calculation of the objective correspond to the N_p future step times. Because the solution methodology includes the use of an optimization routine at each time step, constraint incorporation is straightforward, and input constraints can be included in magnitude-constrained (76.15) and rate-constrained (76.16) forms. Output constraints can be included, but these may lead to infeasibilities in the optimization problem, much as state constraints do in optimal control. One option is to *soften* the constraints by including them as additional weighted terms in the objective function [76.36]. At each sample time, measurements from the system are used to update the states or outputs of the model, and the optimization problem is solved. The first input move change is implemented, and the process repeats at each following sample time (as shown schematically in Fig. 76.5). In the case that measurable quantities are sampled at different intervals, the update rate of the model can be variable (this is referred to as a multirate MPC formulation [76.37]). When measurements are not collected at each sample time, multiple inputs in the sequence $\Delta\boldsymbol{u}(k|k)$ can be implemented. The structural advantages of MPC, including the online solution of an optimization problem that incorporates available patient information, are significant, but a key drawback of this control structure is the challenging analysis of algorithm performance. Stability guarantees, which may be required by the FDA before an algorithm can be deployed in an ambulatory setting, often require the use of endpoint constraints or long prediction horizons (i. e., large N_p or *infinite-horizon* formulations), which may limit the achievable performance.

76.3 Techniques and Applications

The potential scope for automation and control in biomedical problems precludes a canonical review here. Entire journals are focused on biomedical problems from the engineering perspective (e.g., *IEEE Transactions on Biomedical Engineering*, *Annals of Biomedical Engineering*, *IET Systems Biology*), and mainstream control journals (e.g., *Automatica*, *Journal of Process Control*, *Control Engineering Practice*) also publish biomedical control papers. There are also journals focused on the tools as they apply to classes of problems (e.g., *Journal of Pharmacokinetics and Pharmacodynamics* for PK and PD modeling tools). Beyond the diabetes and cancer case studies discussed below, a wide variety of problems have been addressed, such as human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS), blood pressure, and anesthesia, among others (some recent review articles include [76.9, 38, 39]).

76.3.1 Type I Diabetes Modeling and Control

Diabetes has been a popular biomedical modeling and controller design case study for almost 50 years [76.40–44]. The development of models of glucose–insulin interaction, sometimes including additional hormones, substrates, or contributions, has an equally long history [76.40–42, 45–56]. In order to estimate the parameters in these models, tools from Sect. 76.2.1 are employed, and the model structures can be of either compartmental (Sect. 76.2.2) or physiologic (Sect. 76.2.3) form. With a model in place to represent the patient (i. e., patient = model), for use in controller design (i. e., model-based optimal control using tools from Sect. 76.2.5), or both (i. e., patient $\neq$ model), a control problem can be formulated. One option is to pose a single-input single-output control problem, the formulation of which is quite similar to the continuous processes seen in the chemical industry for decades: a manipulated variable (insulin delivery), with a steady-state value (pancreatic insulin release in a healthy patient), is altered to maintain a controlled variable (glucose concentration) within a small range of its nominal value. Normoglycemia is generally taken as circulating glucose concentrations in the range 70–120 mg/dl [76.57], with a nominal value between 80 and 100 mg/dl. Insulin delivery for type I diabetic patients, who have no insulin release from the β-cells of the pancreas, is altered in order to control glucose concentration. Clinical approaches at present involve intensive subcutaneous insulin therapy [76.57, 58] or continuous subcutaneous insulin infusion via mechanical pump [76.59].

Based on this traditional control configuration and the control schemes introduced in Sect. 76.2.5, the glucose control problem can be posed in the model-predictive control framework [76.42, 43], as shown in Fig. 76.6. Using glucose concentration measurements (at 10 min or faster intervals), insulin delivery rate would be changed in order to regulate ambulatory diabetic patient glucose levels in response to meal disturbances. Controller tuning would require rapid rejection of meal disturbances (to keep glucose levels below 120 mg/dl), but also aggressive down-regulation of the controller so that post-meal glucose concentrations remain above the hypoglycemic level of 60 mg/dl, which can be dangerous to patients [76.57, 58]. Furthermore, significant levels of measurement noise accompany each glucose observation. The potentially conflicting objectives of aggressive response and noise suppression challenge model-based algorithm designers. Simulation studies of control algorithms have focused on the type of control needed [76.60], providing upper bounds on achievable control [76.42], or evaluating the potential effects of measurement or other disturbances on closed-loop performance [76.43]. A key hurdle at present is the glucose sensor, as the FDA has not approved any real-time glucose sensor for use in a closed-loop control algorithm.

One focus of improving diabetes treatment via automation is the use of run-to-run control (commonly deployed in the batch processing literature) in designing insulin dosing protocols [76.61,62]. Here, patient glucose concentrations are not sampled at fixed short intervals, but instead the measurements taken by patients over a typical day are used to improve day-to-day performance of their glucose control. In the context of Fig. 76.6, the controller and insulin pump are replaced by the patient (who will determine insulin delivery amount) and their delivery mechanism (pump, subcutaneous injection, etc.); Fig. 76.7 shows a potential configuration of a wireless sensor communicating with the combination data storage device and insulin pump. By reformulating this problem, the use of advanced control and automation techniques has the potential to make a rapid contribution to the treatment of diabetic patients instead of suffering from the critical flaw in artificial pancreas deployment highlighted above: the lack of FDA acceptance of a glucose sensing

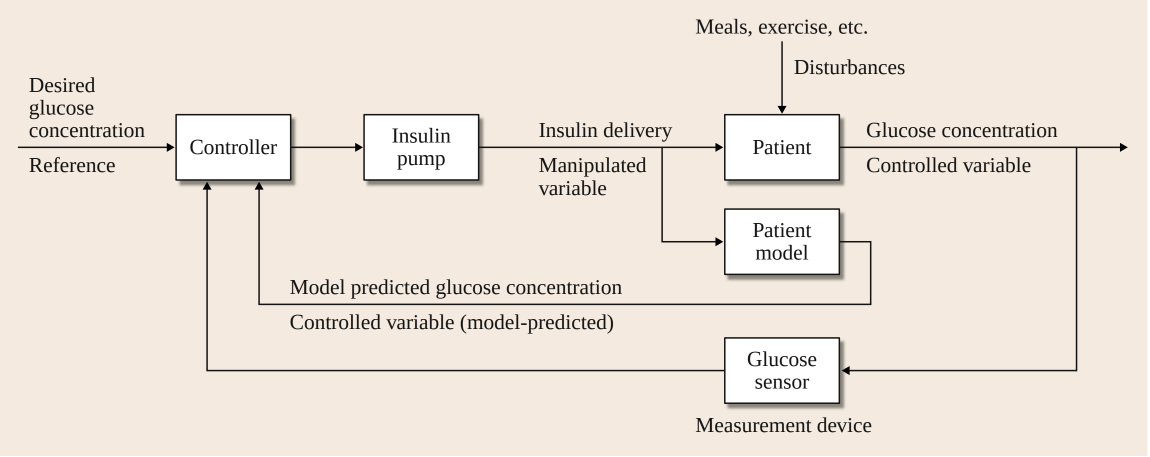

Fig. 76.6 Block diagram structure for model predictive control, as applied to the diabetic patient control problem

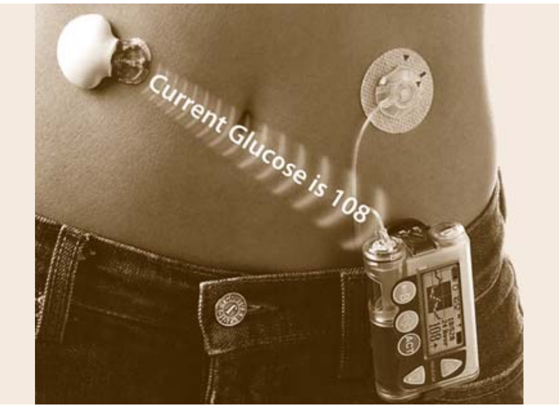

Fig. 76.7 Diabetic patient using a wireless subcutaneous glucose sensor communicating the measurement to the data storage device. This device also includes the insulin pump mechanism; note that the pump is not altering insulin delivery rate based on the glucose measurement unless commanded to do so by the patient (courtesy of Dr. Cesar Palerm, Medtronic Diabetes)

device for use in the closed loop. In fact, the run-to-run algorithm can provide robustness to interpatient differences [76.62], which is important given the span of patients that such an algorithm could encounter.

Changing the focus from ambulatory diabetes to the critical-care setting, the potential for impact is significant [76.63–65]. In postsurgical patients, glucose control via insulin administration can dramatically reduce morbidity and mortality. The altered metabolic state in these patients is similar to the diabetic condition, in that patients are hyperglycemic with low insulin sensitivity. Hence, the automated administration of insulin to regulate glucose concentration could assist in patient recovery. While measurement noise and rate would (likely) be unchanged from the ambulatory setting, other challenges manifest. First, individual models of patients are not available a priori, and population models are insufficient for use on specific patients because individual insulin sensitivity will vary widely. Furthermore, the dynamic state of recovering patients would lead to time-varying insulin sensitivity requiring time-varying model parameters. A patient model updating mechanism, such as recursive least squares (assuming a linear parameterization of the model), is required. Given the present legal and regulatory climate, a high-level safety and fault-detection layer for the algorithm would need to be developed. Alternatively, the algorithm could be implemented as a semiclosed decision support system with medical professionals affirming or declining the recommendation of the updating algorithm. In the context of bringing an automated system to market, the decision support system in critical care could be the most rapid approach because collecting a nonautomated measurement and allowing medical professionals to intervene in therapy has the lowest *energy barrier* to review board approval.

A concern with any insulin delivery system is the potential for overadministration, as this could lead to hypoglycemia and possibly death. Adding a second channel to the closed-loop system could alleviate some of these issues. A model-based structure using both insulin and glucose has been proposed [76.66, 67], where insulin is added to reduce glucose levels, and glucose infusion is used to elevate glucose. To keep glucose from being administered continuously, an *output regulator* formulation is employed (a modification of the MPC scheme in Fig. 76.6 and Sect. 76.2.5), such that positive glucose infusion rates are penalized at a lower level than deviations in glucose concentration from the reference value. The result is that glucose is infused only when predicted glucose levels drop below the basal level. While numerically superior, this approach is more relevant to use in a clinical, rather than ambulatory, setting, as patients are unlikely to desire a two-pump/two-needle (or two-infusion-line) device. Also, a high-dextrose solution is an excellent culture medium for bacteria, so sterility in the nonhospital setting would become an even greater issue for these patients.

As McGarry highlighted in the 2001 Banting lecture, glucose and insulin are not the only important endogenous compounds in diabetes. Type 2 diabetes typically involves the dysregulation of fatty acids (FAs); there is also significance of FAs in insulin-dependent diabetes as metabolic interactions exist with insulin and glucose. Using the minimal model [76.41] as a basis, an extended minimal model of glucose/insulin/FA has been constructed [76.55] using data from the literature and the tools of Sects. 76.2.1 and 76.2.2 (see the schematic in Fig. 76.8). While this model is not mechanistic, it does capture the interactions of glucose, insulin, and FAs; furthermore this model is a low-order parameterization, which would facilitate tailoring to an individual patient.

Finally, meal disturbances are not the sole challenge to diabetic patients, and hence automated insulin delivery systems. Exercise alters glucose and insulin kinetics [76.68, 69], and models of these processes have been proposed in both physiologic [76.54] (Sect. 76.2.3) and *minimal* [76.56] (Sects. 76.2.1 and 76.2.2) forms.

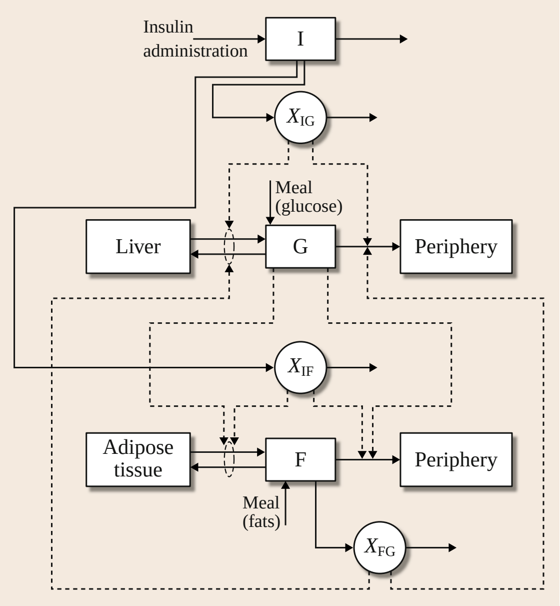

Fig. 76.8 Schematic of interactions between insulin (I), glucose (G), and fatty acids (F). Peripheral tissues consume glucose and fats, while the liver and adipose tissue serve dual source/sink roles for G and F, respectively. Meal consumption increases glucose and fatty-acid levels, and insulin administration drives circulating insulin level. *Dashed lines* represent the effect of one compound on another (G on F dynamics, for example). The X_{ij} *blocks* represent additional dynamics (equations) that alter the extent and duration of effect of i on j (e.g., insulin on glucose through X_{IG})

Again, these models are more macroscopic than mechanistic, but they are able to capture the important responses for the purposes of glucose regulation in diabetic patients. While the population-level variability of the model parameters remains to be characterized (which is also true of the FA models, above), the proposed structure does allow preliminary analysis of control structures to establish feasibility and potential performance of automated glucose control systems.

76.3.2 Cancer Radio- and Chemotherapy

Cancer is a collection of diseases resulting from a series of genetic mutations and characterized by an imbalance between cell proliferation and apoptosis, or programmed cell death [76.71]. If untreated, cancer leads to organ failure and the death of the host organism. One in four deaths in the USA in 2008 was projected to be from cancer, claiming over 565 650 lives [76.72]. In addition, the total disease burden, including treatment costs and loss of productivity, was estimated at US$ 219.2 billion in 2007, providing both societal and monetary reasons for improving cancer treatment [76.72]. Unlike insulin-dependent diabetes, cancer is not a single disease, and therefore, no *silver bullet* (i. e., insulin) exists. Hence, cancers must be addressed individually; e.g., pancreatic and breast cancers are separate diseases with different treatment options and chemotherapeutic choices.

Accessible cancers are removed surgically. Alternatives or complements to surgery include systemic chemotherapy and targeted site-specific treatment, such as photodynamic therapy (PDT) or radiotherapy (RT) [76.73, 74]. RT is often used in place of surgery because the tissue surrounding the tumor is too sensitive to permit surgical excision (e.g., tumors located near the spinal column). PDT is used alone, or as an intrasurgical procedure, to kill tumor cells located at the tumor margin that are invisible to the human eye. All cancer treatments are usually complemented by systemic chemotherapy for two reasons: (i) small remote metastases are often present by the time cancer is detected; and (ii) chemotherapy is the only treatment that is *whole body* in nature, thereby giving it the ability to indiscriminately attack metastatic lesions before they are clinically diagnosed. Hence, automation advances in this area address targeted therapies and chemotherapy.

A key advance in RT, which requires a significant automation component, was intensity modulation (IMRT) [76.75, 76]. A linear accelerator source (Fig. 76.9) provides radiation that has its fluence mod-

Fig. 76.9 IMRT gantry and linear accelerator source (figure originally published in [76.70])

ulated across the beam width, thereby providing prescribed radiation doses to a target tissue volume. By using a rotating beam gantry and placing the patient on an actuated table, critical tissues can be delivered lower doses through optimization of radiation dose to a particular planning volume. Mathematical models are constructed based on fundamental physics of radiation, with refinements based on the interaction of endogenous absorbers and scatterers with the administered radiation beam(s). Collaborative work between engineers and clinicians (such as [76.76]) has provided advanced offline algorithms for optimizing the treatment dose. The state of the art in RT is image-guided radiation therapy (IGRT) [76.73, 74]. This extends IMRT techniques to include real-time adjustment of the planned dose in order to reduce interfraction (positional changes of anatomical objects between the fractions of a radiation dose) and intrafraction (real-time motion of tissues in response to actions such as breathing) spatial uncertainties. From a calculational perspective, this changes a mixed-integer programming (MIP) problem, as solved in [76.76], into either a mixed-integer dynamic optimization problem [76.77, 78] or a dynamic control problem using the MIP solution as a reference.

Model-based approaches to cancer chemotherapy treatment design are an active area of research. Core to this approach is the existence of models describing PK (the effect of the body on the drug), untreated tumor growth (generally using the Gompertz model [76.79], which has been shown to capture solid-tumor progression in human patients), and pharmacodynamics (the effect of the drug on the body, including both antitumor effect [76.80, 81] and toxicity [76.82]). These models are constructed using compartmental (Sect. 76.2.2) or physiological (Sect. 76.2.3) approaches, depending on the amount of data available. Population tools (Sect. 76.2.2) are also important, as the cancer-affected population is heterogeneous. A common solution technique for the chemotherapy dosing problem is optimal control [76.33, 83, 84] (Sect. 76.2.5), where the following two-point boundary-value problem is posed: minimize tumor volume at the end of a fixed time period subject to constraints on drug dose (magnitude), path constraints (states, as governed by the model dynamics), and in some cases explicit representations of toxicity (e.g., neutrophils [76.85]). An alternative formulation and solution method uses mixed-integer programming [76.86–88]; advantages of this approach include path constraint satisfaction and extensibility of the framework to additional constraints. The existence of nonlinearities (beyond the bilinear kill term) in the PK or PD models causes additional challenges for their solution, requiring either parameterization [76.87] or mixed-integer nonlinear programming techniques (for details on these methods, see [76.89,90]). A key change in formulation introduced in [76.87] is the use of a receding horizon strategy instead of the fixed final time (as in the latter part of Sect. 76.2.5). This is consistent with clinical practice: the patient is treated until disease progression or cure, thereby making the final time formulation clinically irrelevant.

76.4 Emerging Areas and Challenges

In a 2001 perspectives article [76.91], *Morari* and *Gentilini* describe the state of process control, and in a larger context, automation, as "... a victim of [its past success]: it has reached a plateau and turning point." The remainder of their article highlights biomedical processes as an area where, "...control engineers [can] have significant impact," because automation and automatic control were not commonly employed. While there have been some changes since 2001, the potential impact of automation and engineering on biomedical practice remains significant. In this regard, this chapter has introduced a set of challenges and tools for use in melding systems engineering techniques with biomedical problems. The case studies are areas in which the author is active; additional opportunities abound for those motivated to: (i) learn the biology, medical practice, and automation need of a disease (e.g., inflammation, infection, regenerative medicine), and (ii) work closely with collaborators in complementary fields to address the disease of interest (e.g., clinicians, biologists, engineers, mathematicians, etc.). Related to some of the challenges that began this chapter, the emerging areas and challenges below represent areas where systems engineering and automation can be employed to advance science and disease treatment. These areas align along a key principle of model-based control: model quality dictates theoretically achievable control system performance [76.92]. Hence, the biomedical goal is to construct *mechanistic* models, when possible, and to understand the *context* of the model, which may serve to limit the prospective use of the model to certain scenarios.

76.4.1 in vitro Physiological Systems

The basic science of biomedicine often begins with cell culture and in vitro experiments. However, a key issue in translating cell-only experimental results to live animals is the disconnect between *cells in a dish* and *cells interacting*. One approach to this problem has been coculturing of cells to allow cellular crosstalk and to allow the development of three-dimensional structure that better mimics physiology. This is a technique used in blood–brain barrier research [76.93] to develop in vitro tests for neurotoxicity. For PK analysis, many drugs are cleared by the cytochrome P450 enzymes in the liver but cause toxicities or effects elsewhere in the body. Hence, an in vitro liver cell culture could be used to analyze drug kinetics; one such option, although the cells are encapsulated in a polymeric coating, is described in [76.94]. A secondary concern beyond three-dimensional (3-D) structure is spatial heterogeneity, which may be more difficult to recreate in vitro [76.95].

A potential system for in vitro testing of drug PK would be a fully integrated physiologically motivated cell culture system: cells of different types growing in culture, with fluid volumes for each cell type corresponding to in vivo physiological volume; fluid flow and connectivity allowing intercell *crosstalk* within and between cell types (*simulated* physiology); relevant compartments for evaluating effect, as appropriate (e.g., tumor cells in culture for cancer PD analysis); and the entire system automated for sensing and control. In the context of cancer drug PK and PD, the incorporation of tumor cells would alleviate two shortcomings commonly present in current in vitro analysis: (i) clinically invalid pharmacokinetic profiles, where the tumor cells are bathed in a constant concentration of drug for a period of time, and (ii) cell kill analysis based on the aforementioned pharmacokinetic profile. While the mathematical analysis of tumor cell kill under time-dependent pharmacokinetic profiles is more complicated than the constant-concentration approach used presently, the use of in vitro physiological systems could serve to reduce the number of animal studies necessary in drug development while also improving the translation of in vitro results to the toxicity and efficacy studies that have to be performed.

76.4.2 Translating in vitro to in vivo

The transition from in vitro to in vivo provides a serious challenge to modelers and treatment designers. Physiology may provide an advantage, as the connectivity between organs in animals is well understood. Organ weights and blood flow rates to individual organs are available in the literature for a variety of species, including *toxicologic man* [76.96]. However, this detailed approach assumes a model of physiological structure, which is not the generally applied practice in clinical drug development. As described in Sects. 76.2.2 and 76.2.3, compartmental models are more commonly employed in the (pre)clinical setting due to the smaller number of parameters, reduced mathematical complexity, and the relative ease of parameter estimation. In this less detailed structure, however, the method for incorporating in vitro information is ad hoc. Hence, a more mechanistic approach is desired when significant in vitro information is available because the mapping to the in vivo situation will be improved.

As discussed above, animals are not humans. The compartmental and population-based PK models often developed in animals rely upon allometric scaling [76.97, 98] to address the interspecies differences in dynamic profile. While imperfect (as witnessed by the dearth of PK-driven model-based treatment designs deployed in the clinic), this scaling principle can provide useful insight for selecting first-in-human doses and times to sample during phase I trials. Translating information relies to some degree on mechanistic accuracy at the cellular level, thereby limiting the *unknown* factors to the physiologically connected tissues. In some cases, carefully constructed physiological models can be successfully scaled from animals to humans by accounting for changes in physiology, such as body fat percentage, as seen for the lipophilic anticancer drug Docetaxel [76.10]. Often this requires assumptions, such as equivalent plasma protein binding characteristics (potentially based on binding information from in vitro studies), and similar mechanisms of clearance (liver metabolism, elimination in urine, etc.). Under these assumptions, the human physiologically based pharmacokinetic (PBPK) model (Fig. 76.4) can be successfully constructed by using the metabolic and clearance parameters as the degrees of freedom in fitting human plasma data. When inconsistencies between the scaled PBPK model and human data manifest, relaxing the assumptions and fitting novel mechanistic behaviors to the human plasma profile is required. The resulting model at the human scale can provide information that would otherwise be unattainable in humans, such as estimated drug concentrations in key tissues (e.g., brain) or those prone to toxic side-effects (e.g., liver, kidney, white blood cells).

76.4.3 Model and Network Structure Identification

How can one develop a mechanistically accurate model when limited measurements are available? This is simultaneously one of the greatest advantages, and most severe limitations, of systems biology. Through mathematical models, a large combination of model structures representing observed behaviors can be quickly constructed and tested with a particular data set. However, the challenge is in identifying which model is *correct* mechanistically, to the degree that the data set can provide such information [76.99]. These model-based methods allow extrapolation to estimate unknown quantities, but can also be used to *close the loop* on (systems) biology [76.100]. Close collaboration between experimental biologists, clinicians, and modelers can provide the feedback required to explore the predictions of systems biology models from the intracellular to the organism scale. Experimental resolution defines the scale of the study, and simultaneously provides context for interpretation and bounds limiting extrapolation. Models relate the perturbation to the observed responses, and an event may be represented by a wide range of models or even model classes. It is at this point that unifying frameworks, as discussed in [76.100, 101], provide *engineering judgement* in the construction of complex system models.

76.5 Summary

From an automation perspective, the context in which models will be used plays an important role [76.38]. In order to employ a model-based algorithm in a clinical setting, the model must be robust enough to capture clinically relevant behavior and the algorithm needs to reliably return a clinically deployable treatment that benefits the patient. Based on the increasing complexity of the underlying biosystems models, in terms of both structure and computational complexity, the algorithmic needs for treatment design approaches are significant. While these model-based treatment algorithms will not change the role of the clinician in quite the same way that computer-controlled systems have affected the chemical plant operator, a mathematically rigorous approach to biosystems analysis and disease treatment has the potential to benefit patient treatment – the endpoint objective of automating biomedical treatment decisions.

77. Automation in Hospitals and Healthcare

Brandon Savage

Healthcare is a complex industry, but yet it lags behind virtually all others in automation and use of information technology (IT). For healthcare, technology serves as an untapped catalyst for higher efficiency, lower cost and broader access to care. The appropriate application can minimize medical errors, promote better management of chronic illness, and enable clinicians to intervene earlier and anticipate prognosis. Additionally, medical informatics provides the tools to generate new insights about both individuals and entire populations through data analysis and visualization. These systems can also be used in support of continuous quality improvement efforts as well as to reduce inefficiencies. While significant strides have been made in the implementation of medical informatics, there are numerous challenges to resolve before we will be able to realize the full benefits of healthcare IT.

Automation is so ubiquitous in our daily lives that few of us give it a second thought. Whether the automated teller machine (ATM), a barcode scanner, or wireless communication, we embed automation as a fundamental mechanism of our daily lives.

It's stunning to notice how few parallel examples exist in the average hospital or physician office, when the exchange of accurate information can literally be a matter of life and death. In today's healthcare system the majority of medical records are still kept on paper – and most of them, including prescriptions, are still handwritten. Even most electronic are commonly in stand-alone systems, and unlike ATMs, are not interoperable and cannot share information.

As an example, if you live in Duluth and need to check your bank balance while visiting New York City, it's easily within reach. If you're ill while in the Big Apple and are taken to a hospital emergency department, it will be virtually impossible for the medical staff to check your medical record for allergies and past history. And, only a few healthcare institutions use barcode scanning to confirm accurate dose and treatment administration.

Managing the complexity of healthcare warrants the need for automation that same complexity is also the reason effective automation is so difficult. There are thousands of data and decision points in the course of treatment. As medical knowledge expands at a breakneck pace, what we define as today's best practice and standard protocol, may not exist tomorrow.

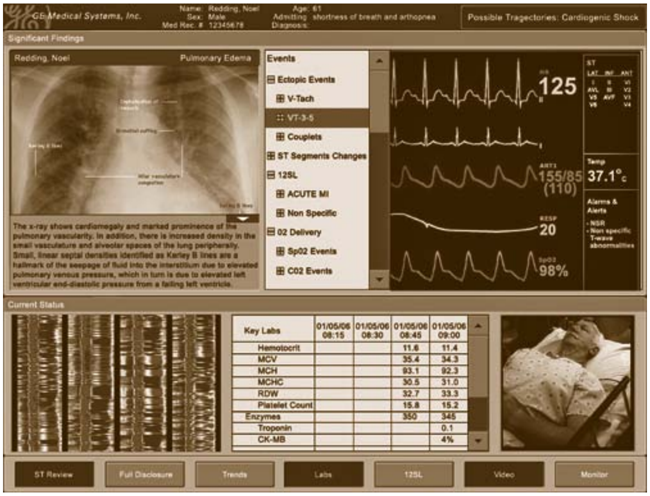
77.1 The Need for Automation in Healthcare

While information technology has transformed other industries, the healthcare industry (especially in the US) remains largely paper-based. This may have been sufficient in the days of the family physician who made house calls, but is inadequate to meet the needs of today's complex healthcare environment. Medicare patients, for example, see an average of three different providers regularly – but without a digitized record the clinicians often lack a complete picture of any patient's medical history. Additionally, medical information collected in the physician's office is stored separately from records related to hospital admissions.

The impacts on the patient and the healthcare system range from the merely inconvenient to the potentially (and all too often) fatal. Without access to a complete medical record, clinicians may inadvertently prescribe medication to which the patient is allergic, or one clinician may unwittingly prescribe a drug that is harmful when taken with another medication prescribed by a different practitioner.

Even when records do exist in electronic form, the information cannot be readily shared because the systems are not interoperable. Within a single institution, interfaces may be required just to move data between clinical and financial information systems, for example, or between the system that holds pharmacy data and the one in which nurses document a patient's vital signs.

Beyond sharing between information systems, sharing information among healthcare organizations is even more complex. There is no single standard for how medical information is represented electronically, so data that exists in one vendor's system cannot be used by a different vendor's system. Overcoming the barriers to interoperability will have a significant impact in accelerating the adoption of electronic medical records.



Name: Redding, Noel
Sex: Male
Med Rec. # 12345678
Age: 61
Admitting Diagnosis: shortness of breath and arthopnea

The x-ray shows cardiomegaly and marked prominence of the pulmonary vascularity. In addition, there is increased density in the small vasculature and alveolar spaces of the lung peripherally. Small, linear septal densities identified as Kerley B lines are a hallmark of the seepage of fluid into the interstitium due to elevated pulmonary venous pressure, which in turn is due to elevated left ventricular end-diastolic pressure from a failing left ventricle.

Key Labs	01/05/06 08:15	01/05/06 08:30	01/05/06 08:45	01/05/06 09:00

Enzymes			350	345
Troponin				0.1
CK-MB				4%

Fig. 77.1 Example of healthcare visualization and monitoring automation to prevent medical errors

The discussion of interoperability begs the question, however, *What are the real benefits of automation in healthcare?* In fact, the benefits are considerable across the entire spectrum of care.

Consider *patient safety*. Every year, between 50 000 and 100 000 people die in the US as the result of preventable medical errors [77.1]. Countless others suffer less severe injuries. Errors arise in many different ways, from prescribing the wrong medication to performing surgery at the wrong site. Confusion arises when two different patients have similar names, or when patients are moved from one hospital room to another. A misplaced decimal point can result in a patient getting less than a therapeutic dose of a drug, or a tenfold overdose:

- Incorporating alerts into electronic medical records can help ensure the completeness and accuracy of the record. The system can remind clinicians to fill in missing data such as allergy information, or in the case of surgery which side of the body is to be operated on.
- Automating the medication-ordering process can eliminate hazards that arise from illegible handwriting; in hospitals, it can shave hours off the time between when a drug is ordered to when it is administered. When expert rules are incorporated, the system can automatically suggest appropriate medications based on the patient's current condition, past medical history, age and weight, and even the list of drugs that will be paid for by the patient's insurance.
- In addition to electronic ordering, closed-loop medication management automates both the dispensing and administration of drugs to ensure that the *five rights* are met – i. e., that the right patient gets the right dose of the right drug via the right route at the right time. Nurses scan barcodes on each unit dose of medication and on a hospital patient's wristband; if there is a mismatch, the system generates an alert that can prevent the error.
- When the drug Vioxx was recalled, most physician offices had to resort to reviewing every single file by hand to determine which patients were taking the drug, resulting in delays of days or weeks before

> patients could be notified of the recall and given an alternative prescription. Clinics that had electronic record systems, on the other hand, were able to compile lists of which patients were taking Vioxx and generate notices to their primary care physicians within a matter of hours.

In the treatment of *chronic illness*, a handful including cardiovascular disease, diabetes, and asthma, are responsible for the lion's share of medical expenses. Yet, if these conditions are managed appropriately, much of the cost can be avoided and patients can continue to lead long and productive lives without acute flare-ups of the disease. Electronic record systems can automatically generate alerts and reminders to help ensure that patients receive effective preventive care, such as annual eye exams for diabetic patients.

In addition, being able to run outcomes analysis on all patients with a certain condition can help identify trends and determine what treatments are more effective than others within a certain population. This kind of analysis, like drug recall notification, is simply not practicable with paper records, but can be done relatively easily with the right kind of electronic records systems.

Increased Efficiency and Accuracy. At each separate encounter with the healthcare system, patients are usually asked to provide the same basic information including name, date of birth, and insurance. Each time the data is taken down presents an opportunity for transcription error, as well as a frequent source of annoyance for patients. Automated check-in kiosks can let patients review their demographic data on file and make any needed changes, without having to recite the same litany over and over again.

Nurses spend as much as one third of their time on charting and other administrative tasks. Automation can reduce the amount of time nurses spend on documentation, freeing up more time that can be spent on direct patient care. Clinicians can pull patient information from one part of the system to another, so it does not have to be re-entered. Nurses can chart *by exception*, entering only data that is outside normal ranges or that has changed since the last reading.

Unlike paper records, electronic records give all members of the care team simultaneous access to a patient's most up-to-date clinical information. Lab results, for example, are available online as soon as they are completed, avoiding redundant tests. Physicians can check on their hospitalized patients from office or home at any time and enter new orders, rather than waiting for daily rounds.

Considering *consistency of care*, the quality of healthcare varies enormously from one hospital to another, and even within the same hospital from one provider to another. Simple best practices that are proven to save lives – such as presurgical antibiotics or administering beta-blockers to heart attack patients within 24 h – are not uniformly followed, even within a single institution [77.2]. Even with recommended care guidelines and best practices published for numerous disease processes, Americans as a whole receive only 54.9% of the recommended care [77.3], and fewer than half of American children receive timely, needed medical care [77.4]. Additionally, 11% of care received is either not recommended or potentially harmful [77.3]. In large part, this is due to the fact that the already overwhelming body of medical science is growing at an explosive pace, and no individual can keep up with it. Clinicians, like the rest of us, can also be resistant to change – preferring to continue using the same protocol they always have for a certain condition. To promote higher consistency, healthcare institutions can develop standard order sets that are used for specific conditions. While some hospitals use hard-copy versions of such order sets, digitizing them and integrating them with a clinical information system, so they are automatically presented at the point of care can be more effective consistency.

On average, it takes 17 years for a new medical discovery to become part of the standard of care. Clinical information systems can accelerate this process through the use of expert systems that are integrated with the electronic medical record to make recommendations about appropriate treatment and present that information to the clinician at the point of care. Evidence-based practice (EBP) is an approach to healthcare that effectively integrates best practices with the daily activities of patient care, resulting in a consistently high standard of care both within and across healthcare organizations. EBP can reduce inappropriate variations in care while at the same time enabling the appropriate tailoring of best practice to each patient's clinical condition [77.5].

Currently only a few of the largest healthcare institutions are able to implement expert systems in this way; the challenge going forward will be to make the technology accessible to smaller organizations with limited IT resources.

77.2 The Role of Medical Informatics

Since its inception in the 1960s, there has been a steady increase in demand for medical informatics, including dramatic growth occurring in the past decade. The reason for this explosive growth is in how medical informatics provides a foundation that bridges the art and science to address challenges facing healthcare. In order to do this, we ultimately need to move medical informatics beyond the level of information management – acquiring, storing, and moving data – to knowledge management – the ability to synthesize and apply available data and thereby transform the practice of medicine.

The breadth of patient data and how that data is utilized in a healthcare setting is important in understanding the distinction between knowledge management and informatics. There are two categories of patient data. The first is subjective data, such as pain or shortness of breath, that is qualitatively described by the patient. The second is objective data, such as heart rate or weight, which can be verified by external observers.

Objective data can further be broken down into patient demographics (name, age, etc.), observations made by healthcare providers, and quantitative parameters representing the anatomic, biochemical, and physiologic states of the patient. Within the latter category, advances in medical diagnostics are not only creating a more comprehensive picture, they are increasingly shifting from anatomic to physiologic parameters – i. e., functional as opposed to structural data. A computed tomography (CT) scan, for example, can detect an anatomic abnormality in the chest, while a positron emission tomography (PET) scan of the same area can detect metabolic characteristics that suggest the mass is a malignant tumor. Specific biochemical markers are better indicators of the effects of congestive heart failure than are imprecise observations of distended veins in the neck.

Fig. 77.2 Healthcare automation has revolutionized the practice of medicine with innovations to detect and diagnose diseases earlier

Another important shift is from phenotypic data – the observable signs or symptoms of normal or abnormal gene expression – to genotypic data – the underlying genetic code itself. Not only is genotypic data more specific (i. e., there can be many different genotypes that present the same phenotype) but it can often predict disease before any outward symptoms are present. The BRCA-1 gene, for example, presents a significantly elevated risk of breast cancer. Women who have this gene should be more closely monitored so that cancer is detected early, when it is more easily treated; some women may opt for mastectomy as a preventive measure. Genotypes for certain liver enzymes can predict how fast a patient will metabolize a certain medication even before that patient takes the first dose; this enables clinicians to more precisely prescribe the optimum amount of the drug.

77.2.1 Information Management

With this vast array of patient data, information management is a necessary first step in delivering safe, effective, high-quality healthcare. The following are four components of an information management strategy:

- *Acquisition* – the transformation of observable objective phenomena and recordable subjective experiences into data, which can then be stored in paper or digital formats.
- *Collation* – the organization of these data into a navigable structure linking the data to patients and populations.
- *Distribution* – the movement of information from its source to potential users of the data.
- *Access* – the interface that enables a user to query data once it has been distributed.

Failure in any one of these components will result in critical decisions being made based on only a small subset of available data, with impact both financial and physical. It is estimated, for example, that clinicians order approximately $ 2.5 billion worth of redundant laboratory tests annually because they do not have access to previously obtained results [77.6]. The consequence of administering medication without access to complete allergy information can be fatal.

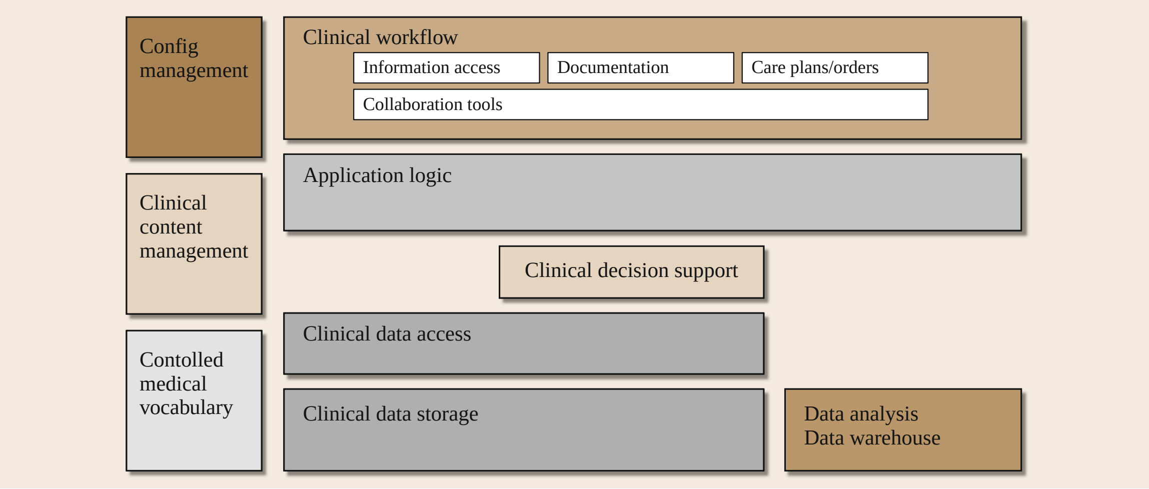

Fig. 77.3 Clinical informatics-oriented view: application architecture connects clinical workflow and is composed of information access, documentation, action plans, and collaboration

77.2.2 Knowledge Management

In many other industries, the value of information management alone has been enough to drive high rates of IT adoption. This is not the case in healthcare, however, where adoption of IT hovers around 20%, despite significant acknowledged potential benefit. The complexity and quantity of medical data decreases, information management as not sufficient to drive adoption. Instead, medical informatics needs to emphasize knowledge management that focuses on the content and use of information technology.

Where information management lags in acquiring and conveying data, knowledge management gains additional value from the meaning, context, and structure associated with that data. For example, consider the relatively simple act of measuring a patient's blood pressure. The systolic pressure reading (the 120 in a reading of 120/80, for example) measures the point at which the peak pressure of the blood in a patient's artery exceeds the pressure of the blood pressure device's cuff as it slowly deflates. The blood flow is detected either by a clinician using a stethoscope or by a transducer in the device. The resulting number can then be recorded, time stamped, and associated with a specific patient. This piece of information is useful but limited – the number alone has little meaning without the context of the data collection: Was the pressure recorded from the left or right arm? Was it recorded using an external blood pressure cuff or a transducer within an artery? Was the patient lying down or standing? (A reading taken while the patient is standing will always be lower than one taken when the patient is sitting or lying down.) Was the observation made by a health professional or reported by the patient? All these bits of information can affect the interpretation and utility of the information.

In aggregating and visualizing data, such as displaying a graph of a patient's blood pressure values over time, an information-driven system is limited in its ability to select appropriate data points. The system may include values that are not comparable (combining both sitting and standing blood pressure, for example) or may fail to include comparable values that were

Fig. 77.4 The complexity and quantity of medical data has been a consistent barrier to the adoption of electronic medical records (EMR) and other clinical technologies

recorded differently (i. e., from a sensor inserted directly in the artery rather than from a blood pressure cuff). A knowledge-driven system, by contrast, could evaluate all possible blood pressure data and include only the appropriate values in the trending task.

With a knowledge-driven healthcare system, clinicians use knowledge management to transform information into insight, which in turn drives more effective healthcare actions. The result is a system that delivers the highest value (i. e., best quality care) at the lowest cost.

Knowledge management comprises three types of knowledge: patient-centered (insight into the available data about a patient), healthcare process (insight into effectiveness and value), and medical (body of medical science and best practices).

There are three key stages of knowledge management that allow these three types of knowledge to drive improvements in the healthcare system: knowledge representation, knowledge generation, and knowledge in action.

77.2.3 Knowledge Representation

The challenge for knowledge representation is to establish the meaning, context, and structure of data, as well as to enable the portability of knowledge across traditional data boundaries – whether software applications, between different locations within a single healthcare organization (such as an outpatient clinic and a hospital), or entirely separate institutions.

In the above example, knowledge representation would provide context to the blood pressure reading and corresponding heart rate measurement and whether the patient is taking any medications that modify blood pressure (information that may have to cross organizational boundaries). Additionally, the system could provide other relevant information from the patient's medical history and from external references, including whether the patient is being evaluated for heart disease (associated with high blood pressure) or a severe infection (associated with low blood pressure).

Knowledge representation is the result of robust medical terminologies that form the fabric upon which electronic medical records can be designed. These medical terminologies consist of controlled medical vocabularies (external standardized referenced dictionaries that attribute specific meanings to concepts that can be linked to data fields) and medical ontologies that contain relationships between concepts to establish the structure of stored data.

In practice, the language of medicine can vary tremendously from one institution to another. While one institution diagnose an episode as a *heart attack* another institution may refer to the episode as a *myocardial infarction*. In the mid-1990s, Medicalogic created one of the first electronic medical records that enforced what was then a controversial design principle: using a centrally managed dictionary of observational terms that all customers could access. The result was a knowledge-based community that allowed healthcare institutions to create advanced documentation forms that referenced the dictionary; these forms could also be shared with other institutions. The members of the community could collaborate on innovation as well as aggregate their data to support the creation of common performance indicators and benchmarks. Vendors also recognized business opportunities in the creation of other content that could be distributed across this customer base. For example, Clinical Content Consultants was founded in 2000 by John Janas III, M.D., and John R. Thompson, M.D., to design and implement interoperable evidence-based forms for clinical decision support in the management of chronic diseases [77.7].

The development of medical ontologies took off in the mid-1990s. The Regenstrief Institute at Indiana University launched LOINC (logical observation identifiers names and codes) to enable the electronic movement of clinical data from laboratories that produce the data to hospitals, physician's offices, and payers who use the data for clinical care and management purposes. At about the same time, the College of American Pathologists teamed up with Kaiser Permanente to expand SNOMED (systematized nomenclature of medicine) to include both a dictionary of medical terms and an ontology of relationships for these terms, both of which were independent of a specific electronic medical record vendor.

The relationships defined in most established medical terminologies are primarily parent/child or synonym-type relationships. Despite their apparent simplicity, the impact on IT system design is dramatic.

Two core IT needs illustrate the impact of an ontological hierarchy on information. The first is search. One of the biggest challenges of an electronic medical record (EMR) is finding information quickly, whether finding the right medication in a list of hundreds of thousands of alternatives or finding the relevant data to aid in performing a specific task. Where search engines such as Google use inherent linkages present within the data (such as hyperlinks) to infer associations, these linkages do not appear in the medical record, and medical ontologies are needed to explicitly articulate the relationships.

The second example is rule writing for decision support or reporting. While electronic medical records systems have allowed institutions to write rules for decision support utilization of rules has been low. In part, this is due to the difficulty of writing rules without an ontology. Consider writing a rule that would generate a list of all patients with lung disease who are also on blood pressure medication. With ontology this is a simple task; without one, it requires compiling exhaustive lists of all possible lung diseases and all possible blood pressure medications, and then mapping this back to specific field names in the medical record. These lists would have to be maintained as new drugs come on the market or new conditions identified.

77.2.4 Knowledge Generation

Knowledge generation uses information technology to augment pulling information from the clinicians' understanding of the medical literature. The daily activities of patient care generate new information about individual patients and entire populations, but the sheer quantity of data is overwhelming. Once data has been digitized, IT systems can synthesize even massive amounts of information into usable insight through two key routes: data analysis and visualization.

Other industries rely on data analysis and data mining as a significant source of insight. In healthcare, where an operating margin of 2–4% is considered exceptional, many institutions have implemented some level of financial data analysis. With respect to clinical data, however, the lack of digitized information has hindered the use of data analysis to generate insight about clinical practices outside the academic research setting.

Data analysis can enable clinicians to make inquiries about the efficacy of daily practice in the same way that knowledge can be derived from controlled clinical trials. A review of data at the population level can reveal patterns that are not observed in isolation. In this way the process of managing patients leads to greater insight about the best way to manage those patients going forward.

For example, it is widely recognized that inducing labor before the 39th week of pregnancy can have deleterious effects that compromise the health of the newborn, yet early inductions still occur with relatively high frequency. In a one-on-one interaction between patient and physician, it is easy to find reasons to induce *this* patient's labor early: late stages of pregnancy are increasingly uncomfortable for the woman, the doctor will be out of town, or other calendar issues come into play. With each individual decision, neither provider nor patient is looking at the bigger picture.

At Intermountain Healthcare, an integrated delivery network headquartered in Salt Lake City, data analysis of almost 40 000 delivers deliveries in 2000–2001 revealed an increased rate of neonatal intensive care unit (NICU) admission for babies induced before week 39 (Fig. 77.5). The research revealed a one to two weeks delay could have avoided as many as 220 NICU admissions. Once this data was available, the institution developed and implemented an evidence-based triage protocol that set a higher threshold for elective inductions. The rate of early elective inductions dropped to 5%, significantly reducing unnecessary NICU admissions. Thus, the generation of knowledge through population data analysis also led to insight that motivated providers to change their practice.

Looking for trends also enables institutions to improve management of patient care. Ideally, these insights will extend beyond clinical knowledge to encompass the process of care. Electronic medical records enable institutions to capture information about cost, clinical data resource utilization, and process times. Using this information, they can begin to understand the consequences of practice patterns and resource allocations, and assess the *value* of the care they deliver. As institutions often focus on cutting costs without knowing the impact on quality, the analysis can demonstrate ways to provide the right kind of care while actually driving down per capita cost. Many examples exist where institutions deliver the highest quality of care with the lowest per capita rates, as consists of complicated processes, resource allocations and practice patterns with multi-fauceted practice patterns attribute. This analysis will become essential as more third-party payers adopt pay-for-performance programs that base reimbursement on quality rather than quantity of care.

With paper records, physicians write summaries that effectively filter out much of the granular information about a patient's condition. Other information may be stored in archives, or simply filed in some other part of the healthcare organization where they cannot be immediately accessed. One of the paradoxes of digitizing information is that the amount of accessible information quickly becomes so overwhelming that clinicians can no longer sift through all of it to find the relevant information they need.

Data analysis can also be used to help providers synthesize the vast amounts of information that are

Part H | 77.2

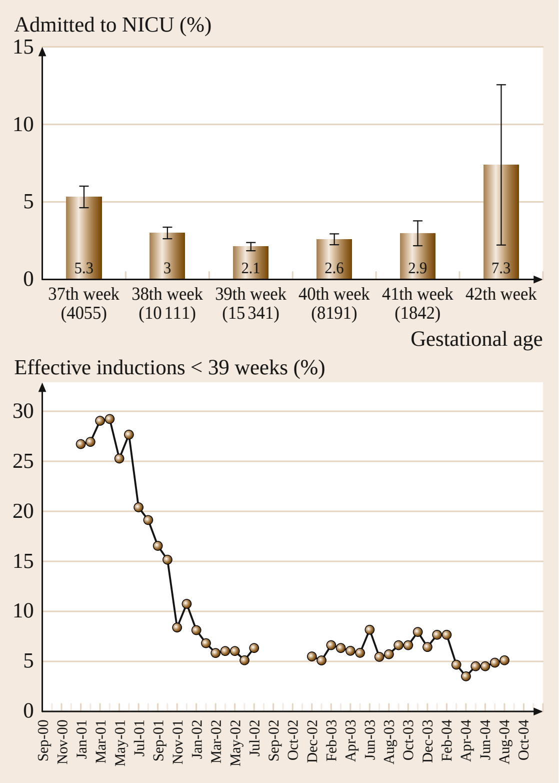

Fig. 77.5 Results of study by Intermountain Healthcare that analyzed almost 40 000 deliveries in 2000–2001 to reveal an increased rate of NICU admission of babies induced before week 39

available about a single patient. For a patient with multiple chronic diseases, a clinician needs to understand the interplay of a variety of different test results and how individual tests vary over time. Visualization techniques can facilitate a clinician's evaluation of a patient by supporting the cognitive tasks necessary for making judgments patient about the patient's care. An information system that automatically collects the relevant information and presents it in an easy-to-read format can significantly facilitate a clinician's evaluation of a patient. With such an IT system in place, the clinician can work systematically from problem to problem, rapidly focusing on the next steps and how they interact. The presentation can be further augmented by embedding relevant contextual information for any task the clinician is handling. For example, if a provider is ordering antibiotics the system would automatically display allergies, drug interactions, previously prescribed antibiotics, and bacterial sensitivities.

The most effective clinical information systems can intelligently sift through vast amounts of data, identify pertinent patient information, and synchronize seamlessly to a provider's. In this setting, visualization includes the ability to organize data based upon the patient's condition and determines what is and is not relevant.

Knowledge generating systems make it easy for physicians to focus on the pertinent positive (abnormal) findings and the pertinent negative findings (normal results that reduce the likelihood of a specific diagnosis). In the case of chest pain, pertinent positive findings include high cholesterol, sudden onset of pain, smoking, and family history of coronary artery disease – all of which suggest that the patient is at risk for a heart attack. On the other hand, if the patient is relatively young with no family history of the disease, has normal lab tests, electrocardiogram (ECG) and other vital signs, and had similar normal findings on a recent emergency department admission for similar pain, the physician may conclude that coronary artery disease is an unlikely cause.

A system without knowledge representation can perform only limited visualization, such as simple graphing of trends, data grids, and composite displays; without insight into the meaning and structure of the data there is little intelligent work that can be performed by the computer. With knowledge representation, the IT system can determine how the available data relates to a patient's active problems and then organize the entire record to minimize the time it takes to review, increasing the likelihood that the provider sees and processes the most relevant information.

Advanced visualization algorithms can be used to look at data in new ways. Heat maps, cluster analysis, multivariate indexes such as severity scores, and patient health dashboards all represent potential means for presenting complicated data using simplified visual metaphors. Heat maps create color-coded views of the patient record highlighting the most active or high-risk areas requiring attention. Cluster analysis is used to graphically represent the similarity between one patient and similar patients in a population. It has been used successfully to predict patients who may be more likely to respond to certain cancer therapies based on the expression of different genes associated with a given type of cancer [77.8]. Other experimental approaches have been used to predict based on numerous factors, which patients are more likely to develop Alzheimer disease [77.9]. Cluster analysis is particularly useful because it enables clinicians to rapidly see associations among different factors even if the underlying scientific principles are unknown.

Multivariate indexes, such as severity scores, combine different observations about a patient into a single score. The human mind is limited in the number of variables it can process simultaneously by collapsing numerous variables into a single score can make it easier for clinicians to see trends that may otherwise be hidden in complex relationships. For example, severity scores can help clinicians identify at an earlier stage which patients are at greatest risk for worsening illness allowing them to intervene earlier and potentially prevent the worst effects of the disease [77.10]. Patient dashboards can be used to combine patient-specific data and severity scores to create a prioritized list of patients, so that the provider can quickly identify which patients are most in need of attention. One sign of well-designed visualization systems is that significantly fewer obtrusive alerts are required to avert provider mistakes; when the data is clearly presented, users are more likely to make the right choices the first time.

Unfortunately there are very few examples of widely adopted systems with detailed knowledge representation, so many of these visualization techniques remain in their infancy.

77.2.5 Knowledge in Action

The next level of knowledge management is to take the knowledge that has been accumulated – from medical research, from a patient's chart, and from data analysis and visualization – and put it to work at the point of care. Too much of the knowledge that exists today is inaccessible to clinicians when and where they need it. IT will build the bridge that enables us to incorporate the extensive knowledge base into the daily activities of patient care, resulting in a consistently high standard of care both within and across healthcare organizations, with fewer inappropriate variations yet still tailored to the needs of the individual patient. When knowledge is embedded into clinical workflow, clinicians are much more likely to actually use the information than they are to consult a static display in a book or on a web site.

In addition to improving care of individual patients, knowledge in action is also a keystone of continuous quality improvement (CQI) efforts, such as the application of Lean manufacturing principles to healthcare. IT enables the analysis of institution-wide data to break down processes into their constituent parts and identify steps that do not add value to the encounter.

The translation of knowledge into action includes digitizing information into a readily searchable form using knowledge representation; converting digitized data into an electronic workflow; and organizing and updating the knowledge database once it has been created. An institution should also rely on its IT infrastructure to provide support reviewing outcomes measures and effectively prioritize implementation of its thousands of evidence-based guidelines.

Knowledge into action can not only help institutions apply existing evidence to the delivery of patient care, but it also enable organizations to localize the practice of evidence based on various populations. The insights thus gleaned can be fed back into the system to further refine and improve the care being provided. The Pacific Northwest, for example, has a higher incidence of multiple sclerosis than anywhere else in the US – so when patients present with weakness or back pain, providers there should consider ordering an magnetic resonance imaging (MRI) sooner than they might elsewhere. This localization can even be applied to an individual patient: a person known to have a gene that predisposes him or her to a particular disease (such as breast or colon cancer) should be treated more aggressively than the general population when potential symptoms are seen. Rather than relying on a clinician to remember and apply all of these minute variations without assistance, institutions can apply expert rules within their electronic

Adult Diabetes Summary Report

Last update: 11/14/2004 12:35:06 PM

PAGE BY: none

Rows: 13 Columns: 1

Metrics	Member	Westside Clinic Physician Associates
Diabetes Quality Score		55.0
Diabetes Patients		258
Percentage with Last HbA1c > 9.0 %		12.40%
Percentage with Last HbA1c < 7.0%		58.13%
Percentage with Last BP < 140/90 mm Hg		73.25%
Percentage with Last BP < 130/80 mm Hg		48.44%
Percentage with Dilated Eye Examination		13.56%
Percentage with Smoking Assessment		68.21%
Percentage with Complete Lipid Profile		99.22%
Percentage with LDL < 130 mg/dl		96.12%
Percentage with LDL < 100 mg/dl		84.88%
Percentage with Nephropathy Assessment		94.96%
Percentage with Foot Examination		53.10%

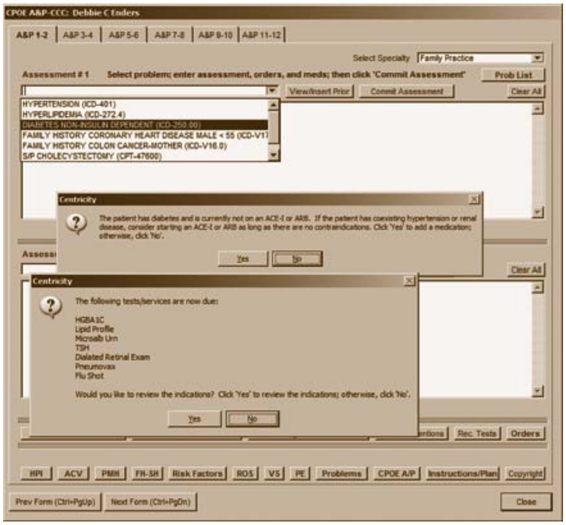
Fig. 77.6 A medical reporting tool. Technology systems like the Medical Quality Improvement Consortium (MQIC) can be used to drive continuous quality of care improvement by capturing current levels of quality. Using encounter forms and decision support rules, clinicians can then alter the effect of the care process and monitor the result of the intervention

medical record systems that will automatically present clinicians with evidence that is most relevant to a particular patient.

One way to bring knowledge into action is through decision support systems; of these, the most commonly used are alert engines. These engines display messages to users in a variety of situations, including:

- A potentially hazardous situation, such as when a clinician is about to order a medication to which the patient is allergic
- A condition that requires action, such as the receipt of abnormal lab results
- Missing data, such as failure to complete a list of known allergies
- A gap in care, such as overdue diagnostic tests recommended for preventive care of a chronically ill patient.

Alerts are intended to be helpful, highlighting simple issues that are easy for clinicians to overlook given the busy nature of healthcare. The challenge is to establish the right level of alerts. For example, the adverse effects of a drug allergy or a specific drug/drug interaction can have different degrees of severity depending on the patient's overall condition. The system would have to determine when an alert is appropriate for a specific patient, and many systems err on the side of showing too many alerts. Unfortunately, there is a threshold above which users experience alert fatigue and begin to ignore alerts – essentially rendering the alerting system useless. In fact, some institutions turn off alerts in their electronic medical record systems because they appear to increase liability (if a clinician ignores an alert) without changing practice.



CPOE A&P-CCC: Debbie C Enders

Select Specialty: Family Practice

Assessment # 1 Select problem; enter assessment, orders, and meds; then click 'Commit Assessment'

HYPERTENSION (ICD-401)
HYPERLIPIDEMIA (ICD-272.4)
DIABETES NON-INSULIN DEPENDENT (ICD-250.00)
FAMILY HISTORY CORONARY HEART DISEASE MALE < 55 (ICD-V17
FAMILY HISTORY COLON CANCER-MOTHER (ICD-V16.0)
S/P CHOLECYSTECTOMY (CPT-47600)

Centricity

The patient has diabetes and is currently not on an ACE-I or ARB. If the patient has coexisting hypertension or renal disease, consider starting an ACE-I or ARB as long as there are no contraindications. Click 'Yes' to add a medication; otherwise, click 'No'.

Centricity

The following tests/services are now due:

HGBA1C
Lipid Profile
Microalb Urn
TSH
Dialated Retinal Exam
Pneumovax
Flu Shot

Would you like to review the indications? Click 'Yes' to review the indications; otherwise, click 'No'.

Fig. 77.7 Example of CPOE and clinical decision support. In this example, a physician has been *alerted* to elements of a diabetic patient's record, including medication management, allergy questions, and whether to document insight gathered from the alert

To overcome these problems, next generation alerting systems will need to have greater granularity in how they define what triggers an alert, taking into account both the patient's condition and the identity of the provider. A patient with kidney disease will always have some lab results that are outside the normal range for the general population, but that reflect the *normal* (i. e., stable) state for that individual. Similarly, alerts regarding the management of a patient's diabetes will be relevant to the patient's primary care provider, but not to an orthopedist who is seeing the patient for an unrelated condition.

An even more effective method of reducing alert fatigue is to initially present information in a way that reduces the likelihood of triggering an alert in the first place. In fact, one may argue that alerts – especially those that interrupt workflow – represent a system defect. A well-designed system should instead ensure that users do the right things rather than relying on alerts to correct errors, and it can do this in large part by how it displays patient data in conjunction with embedded reference information.

In other words, a system should not need to alert a clinician that the drug just prescribed is one to which the patient is allergic. Instead, the list of patient allergies should be displayed and highlighted before the clinician even starts the medication order. An intelligent patient summary screen would display a list of expected diagnostic tests based on a patient's known problems; this list would include the most recent results of all tests that have already been performed, indicate which ones need to be repeated, and prepare (pending the clinician's approval) orders for tests that have not been done. In a single glance, the clinician can easily determine the status of the patient and the appropriate next steps that are required.

Decision support systems are capable of more than simple alerts. Newer decision support systems translate existing best practice guidelines into adequately explicit digital protocols that can be incorporated into a clinical information system to help track and guide care.

While guidelines are common in medicine, the terms they use are often too ambiguously defined to be adequately represented in logic that can be enforced by a computer. A clinician will likely understand what a guideline means if it suggests changing a medication if a patient has not responded within a reasonable time. In contrast, an adequately explicit version of the same protocol would specify that if a patient's blood pressure has not dropped below 120/80 following administration of a maximum daily dose of 200 mg of Metoprolol for 1 month, or if the patient's heart rate has dropped below 50, then the patient should be given a calcium channel blocker.

In order to incorporate knowledge in action, there is a significant amount of work to be done to adequately define protocols and intelligent alerting systems. Existing guidelines tend to be written rather generically, and need to be tailored to the specific needs of clinicians at a particular location. To date, much of this work has been done by a small number of healthcare organizations, organizations, using commercially available systems as a starting point. Because of inconsistent terminologies and the lack of interoperability among systems, however, another – thus, reducing or eliminating the potential for synergies that could accelerate advancement of the technology, does not easily reuse work done at one institution. There have been a number of attempts to create knowledge representations for protocols and alerts that could move across systems, but, to date, none have been successfully and consistently adopted.

Adequately explicit protocols give rise to a dialog over time between the provider and the computer system that jointly determines the next appropriate intervention for care. The fact that a protocol is adequately explicit, however, does not replace the need for a determination to be made as to whether the protocol is appropriate for a specific patient. A patient with kidney failure will have changes in drug metabolism such that some protocols should never be administered. Or a patient who starts on a particular protocol may experience changes that make the protocol no longer appropriate. In other words, a protocol is a method to ensure consistency of care but it does not eliminate the need for careful observation and judgment.

77.3 Applications

Existing health IT systems can be organized by functions they perform and the locations where they perform them. The basic functions fall into five healthcare-separate categories: patient access, healthcare billing, healthcare administration, clinical care, and patient connectivity; a subset of these functions is then tailored to the specific needs of a given care location. Finally interoperability represents the functionality required to share information across the boundaries of healthcare. (There are a number of other core IT functions, such as ERP or customer relationship management (CRM) modules, which are applicable to any business and have been adapted to healthcare, which will not be reviewed here). Although this discussion begins with a separate review of each function, the true power of health IT is recognized only in enterprise systems that tie all these functions together.

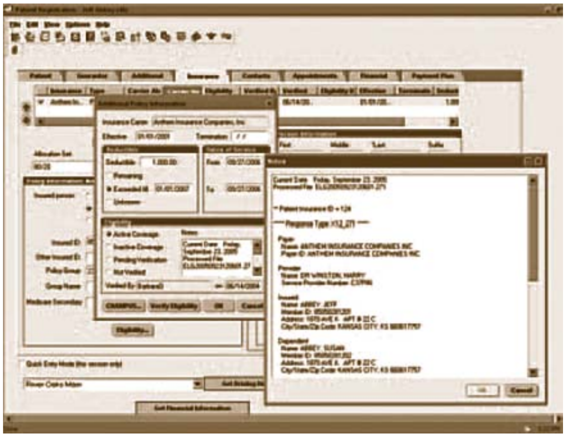
77.3.1 Patient Access

Patient access systems manage how a patient interacts with the healthcare system; they can be further broken down into scheduling and location management. Healthcare scheduling is complex and is key to the efficient operation of a healthcare system. The simplest scheduling systems focus on finding a time slot for a patient to be seen by a specific doctor in a specific clinic. They may also take into account the level of resources or services available at different times of day to help balance the caseload. At the other end of the spectrum are enterprise scheduling systems, which are used to help orchestrate the delivery of care across multiple locations. For patients with complex conditions, these systems ensure that appointments are scheduled in the appropriate sequence and that a patient is not scheduled to be in two different locations at the same time.

Location management functions, commonly referred to as patient administration message (ADT) or admission/transfer/discharge, include tracking the locations of the patient in the hospital and storing basic demographic information about the patient. For inpatient care, the digital management of patient location is crucial to the appropriate provision of services (knowing which patient in which room is to be taken for a CT scan, for example) as well as for accurate billing.

77.3.2 Healthcare Billing

Healthcare billing systems focus on generating charges based upon services delivered and supplies consumed,



Payer
Name: ANTHEM INSURANCE COMPANIES INC
Payer ID: ANTHEM INSURANCE COMPANIES INC

Provider
Name: DR WINSTON, HARRY

Insured
Name: ABBEY, JEFF

Dependent
Name: ABBEY, SUSAN

Fig. 77.8 By establishing a single electronic connection to over 1000 payers, this healthcare application simplifies and automates eligibility checking and claims processing to help drive more efficient workflows and accelerate reimbursement

and then presenting invoices to those responsible for payment (whether patient, insurance company, or some other third party). Both the capture of charges and the billing process itself are fairly complicated in medicine.

Charges comprise both professional service fees (incurred when a clinician performs a service for the patient) and institutional/facility fees (based on the cost of resources consumed and the procedures performed by the institution's staff).

Professional service fees are codified by type and complexity of the service provided, from a simple clinic visit to open-heart surgery. Most IT systems capture these charges by having doctors select specific billing codes from a defined list. Significant training is required for physicians to bill appropriately and legally. More advanced IT systems provide some decision support that reviews the doctor's clinical documentation to help determine the appropriate level of billing for a given service.

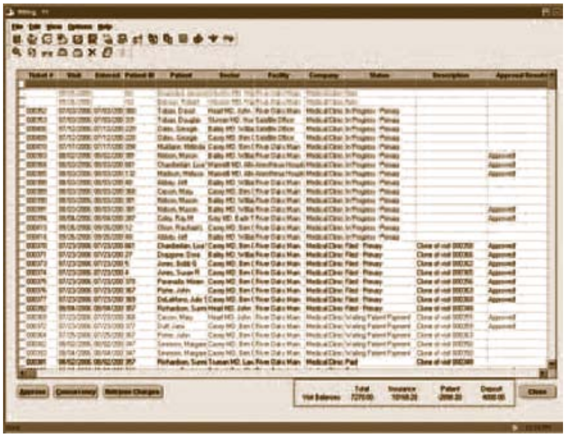


Fig. 77.9 Sophisticated billing solutions will include task management, claims processing, and tools to automate interactions across the healthcare systems

For inpatient care, however, hospitals are not necessarily reimbursed based upon the actual care delivered. Instead there are DRGs (diagnostic related groups) that typically specify reimbursement levels for specific diseases or procedures; it is left up to the hospital to manage cost so as to maintain profitability. As a result, billing systems need both cost accounting and bill management to adequately address the address the revenue cycle. Cost accounting allows institutions to track the cost of performing basic operations and specific care actions. Cost accounting is crucial for an institution to understand its cost structure and optimize its productivity. Billing and revenue tracking are further complicated because reimbursement often comes from multiple sources: government (Medicare/Medicaid) and insurance companies, as well as patients.

Patient billing systems focus on submitting charges to third-party payers in such a way as to minimize rejections and shorten time to reimbursement. Increasingly, both insurance companies and government payers typically require additional clinical documentation to justify the charges – increasing the demand for integration between financial and clinical systems.

Patients are responsible for all charges not reimbursed by either insurance or government payers. Often there are multiple third-party payers involved, increasing the complexity of billing and making the whole process overwhelming for a patient who is also dealing with a significant illness and looming large medical expenses. A billing system that can streamline the process and simplify the experience will have a positive impact on patient satisfaction with the provider.

77.3.3 Healthcare Administration

Healthcare administration systems focus on the business intelligence to understand the operations of the healthcare system. These include financial dashboards and reports, which show the financial operations of the hospital, patient census and bed management, and resource management such as nurse staffing and order communications (the systems that communicate order requests within a hospital). These systems pull information from multiple sources to generate comprehensive views of the healthcare system.

Redundant or inefficient processes can take their toll on an organization's bottom line. Healthcare administration systems can help identify these processes, enabling organizations to streamline their operations, improving both profitability and patient and provider satisfaction. Increasingly, healthcare administration systems have become more dependent on clinical care. As a result, these systems are becoming more closely tied and potentially integrated with clinical systems. One significant challenge for these systems is to get clarity into details of the healthcare process especially at the point of care. Often the point of care is the least digitized and yet has the most significant impact on operations. As the point of care becomes more digitized, it will be easier to understand the healthcare delivery system in detail. This will create new opportunities to understand how cost, decision-making, and workflow affect the bottom line of operations. With greater insight new rules can be built into the point of care through standard operating procedures, workflow management, and decision support.

77.3.4 Clinical Care

The earliest clinical systems to be adopted were dedicated to reviewing patients' test results. Before the advent of these systems, clinicians had to consult multiple sources to get the results of laboratory tests, electrocardiograms, x-rays, and pathology reports for a single patient. Typically the results were available to only a few people at a time – so that different members of the care team could not access them simultaneously – and often the location where the results were stored was not where the clinician was. Results-viewing applications can aggregate data from multiple sources and allow clinicians to access the information from anywhere and at any time, so that the entire care team can have simultaneous access to a comprehensive view of the patient's status.

Another area where there has been significant adoption of IT is diagnostic test systems, which accelerate the process of performing the tests and manage distribution of the results. Most hospitals now have laboratory information systems to manage workflow, task management, and aggregation of data for all the tests performed in the laboratory. Likewise, picture archiving and communications systems (PACS), which are used to capture digital radiology and cardiology images from imaging hardware such as digital x-rays, CT scanners, and MRI scanners, are present at most hospitals and increasingly at outpatient imaging centers. Radiologists use PACS to view and interpret images and provide diagnostic reports. PACS systems have eliminated the need for large (and expensive) film storage rooms; they have also given rise to teleradiology, where radiologists can view and interpret images remotely. This creates new possibilities for business models in which academic institutions can provide advanced services for rural hospitals that may not be able to attract and sustain specialized radiologists.

While these types of systems have been widely adopted, they are often disconnected from the core workflow of patient management and therefore provide little opportunity for the application of knowledge in action. The greatest impact on improving the quality of patient care comes from clinical documentation and computerized provider order entry (CPOE); unfortunately, adoption rates for both of these functions are less than 20% (Fig. 77.10).

Orders comprise all the directions that physicians prescribe for the management of a patient based on all the knowledge available about that patient at a certain point in time. Thus the amount of knowledge available to the clinician at the time of order entry will have a significant impact on the quality of care. CPOE not only ensures that an order is legible and consistently communicated; it also presents the opportunity to opportunity to use decision support to validate the appropriateness of the order prior to it being carried out. Additionally, CPOE allows the creation of sets of orders which can be managed as a group to ensure a given disease is managed consistently. A hospital can create a standard order

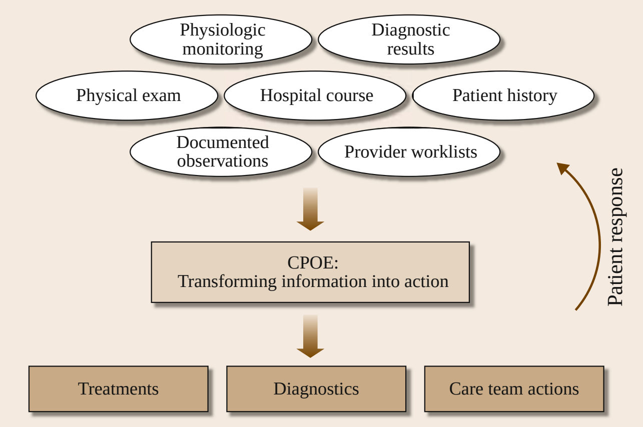

Fig. 77.10 Example of the cycle of care with the use of clinical documentation and CPOE

set for heart attack patients and then rather than having to remember each specific order, the physician can then focus on changing or adding orders needed to tailor care to the individual patient.

Order quality and order consistency were key drivers for a recommendation by The Leapfrog Group (a consortium of large employers concerned with improving the safety, quality, and affordability of healthcare) to recommend that CPOE should be widely adopted [77.11]. The centrality of order entry to workflow has made it difficult, however, to design CPOE systems that were not perceived to slow down the ordering process. In fact, while CPOE may create extra steps for the physician at the time of ordering, this is much less than the time required to correct illegible handwritten orders or address complications that arise from preventable adverse drug reactions. The problem is that the physician does not directly experience the time-saving impact of the workload.

It is only in the past few years, as organizations have recognized the role of change management in the success of CPOE, that adoption of these systems has started to accelerate. One of the key success factors has been to implement enough facets of the IT system to demonstrate value beyond CPOE. Physicians are more likely to adopt CPOE if at the same time they can benefit from information access, data visualization and decision support. Conversely, if CPOE is the only function implemented, so that workflows are split between digital and analog systems, creating unnecessary interruptions in workflow, clinicians will be less likely to embrace the technology.

Another key portion of a clinician's workflow is the documentation process. Healthcare documentation serves four key purposes:

1. It creates a legal medical record describing both the reasoning and activities involved a specific patient's care.
2. It provides a basis for outcomes analysis, population management, and reporting.
3. It communicates one care team member's actions and reasoning to other members of the care team, enabling better collaboration and coordination of care.
4. It assists clinicians to organize their thoughts and plan their actions.

Thus, good documentation systems are more than just sophisticated word processors. Rather, these systems are important for legal accountability, retrospective data analysis, and data mining, as well as for orchestrating and coordinating the ongoing work of the entire care team.

Interdisciplinary documentation, integration of decision support, and integration of key workflow tasks all contribute to extending the value of these systems. It is rare that one provider is responsible for all of the information necessary to manage a single patient. Interdisciplinary documentation allows providers from different specialties and disciplines to contribute to the medical record in an orchestrated fashion, collaborating on shared documents and leveraging documents created by others. Each provider can see the work performed by others and integrate other providers' observations into their own work. The hospital physician who sees a patient once per day relies on the information from hundreds of encounters by nurses, dieticians, physical therapists, and social workers to write one note that sets the direction for the next day of patient care. Similarly, a case manager will integrate the work of the entire care team and synchronize the nursing, physician, patient, and discharge goals all based on the shared documentation of the team.

The more powerful documentation systems combine task and worklist management features to tie the work of documentation into the details of patient care. Because documentation is such a consistent part of healthcare delivery, incorporation of worklists into the documentation process tends to increase the consistency of care delivery.

Providers often use documentation as an important part of their cognitive process, using it to help organize the information available and form their plan of action. The basic structure of a progress note taught to all physicians is called SOAP, which stands for *subjective, objective, assessment, and plan*. Thus, the inherent structure of the note is designed to aggregate current knowledge about a patient, assess the patient and then determine the plan of care. Most documentation notes follow a similar structure. Preserving this cognitive value of documentations is one of the hardest problems to solve in digitizing the documentation process.

Because, as with CPOE, so much reasoning occurs during the process of writing notes, documentation is another key target for decision support systems. Decision support can both initiate the documentation process and occur within the documentation process itself. Decision support initiated documentation focuses on dynamically manage managing the task or action that should occur next. Documentation also becomes the final step and forcing function to make sure that a process actually occurs. During documentation, decision support is used to automatically aggregate information that should be included in the note and prompt for actions that should be considered within the care plan. Documentation links task management, results review, care planning, decision support, and order entry all into a single workflow. The best documentation systems are built to leverage and dynamically interact with all of these functions within the EMR.

One of the next important trends in clinical applications is *near device* decision support. Medical devices are sprinkled across the healthcare system. There are advanced physiologic monitors and ventilators in the intensive care unit, anesthesia machines in the operating room, ECG machines in the emergency department, blood pressure cuffs and intravenous infusion pumps almost everywhere, and new devices entering the home – just to name a few. These devices each have their own innovations and manufacturers seek to find unique and innovative ways to differentiate their products. As a result these manufacturers have targeted ways to make these devices ubiquitous indispensable parts of the care process. Extending the hardware platform at the core of these devices with new software applications that aid in the care process has become increasingly common. Many of these applications can be considered *near device* decision support, as the decision supporting characteristics are managed by the device rather than with a clinical information system. For example many new infusion pumps include the ability to check dose ranges and verify the barcode of medications before they are administered. In fact, some of these pumps will connect to pharmacy information systems to allow the pharmacist to directly program the pumps wirelessly. Even more advanced applications are starting to appear such as ventilators that have embedded weaning protocols that help guide the process of discontinuing the use of mechanical ventilation in critically ill patients. (Ventilators are machines that breathe for patients when they are too sick to breath for themselves. One of the challenges of using a ventilator is helping a patient gain the strength to breathe independently of the machine as they begin to improve. This process is called weaning.) There are numerous applications where software combined with medical devices will help manage complicated and specific care processes. In this space the line between devices and software will begin to blur.

77.3.5 Patient Connectivity

In a given year most people may see their doctor at most 1 h and even patients with all but the most severe disease spend most of their time living their lives independent of the healthcare system. As a result most of the decisions that affect the health of a person are made during the activities of daily life. Choices about diet, exercise, medication compliance, sleep habits, and stress levels all contribute significantly to the real health outcomes that face society. If we are to truly improve the health of a population then we must enable the healthcare system to reach beyond the boundaries of its wall directly into the lives of patients. Essentially, the patient becomes the central member of the care team and effective collaboration becomes key.

With the advent of increased penetration of the Internet into the average family household and increased trends toward patient financial responsibility for healthcare due to employers passing the increase costs of healthcare on to their employees, the patient's role in the IT system has begun to expand.

The most common and demanded IT functions are around managing the patient's access and finances with an institution. Many systems are beginning to allow patients to request appointments online and allow patients to review their complicated billing histories and make payments. These features keep healthcare systems on par with other industries and increase the customer satisfaction of interacting with the healthcare system. Additionally, since these portals receive a fair amount of traffic healthcare, institutions use these portals to provide marketing and relevant institutional information to patients and prospective patients. This is particularly important in urban areas where healthcare systems compete for market share.

Although these finance and access features drive a great deal of consumer satisfaction they have limited impact on the health of a patient. Recently, EMR vendors and dedicated patient portal vendors have begun providing clinically oriented applications. The simplest forms of this application allow patients access to portions of their medical record – such as labs and results – and allow secure communication with between the patient and the physician. These e-Visits have recently begun to be reimbursed by payers as they are becoming more effective and reducing unnecessary and more expensive office visits.

More advanced versions of these applications include true disease management applications, which

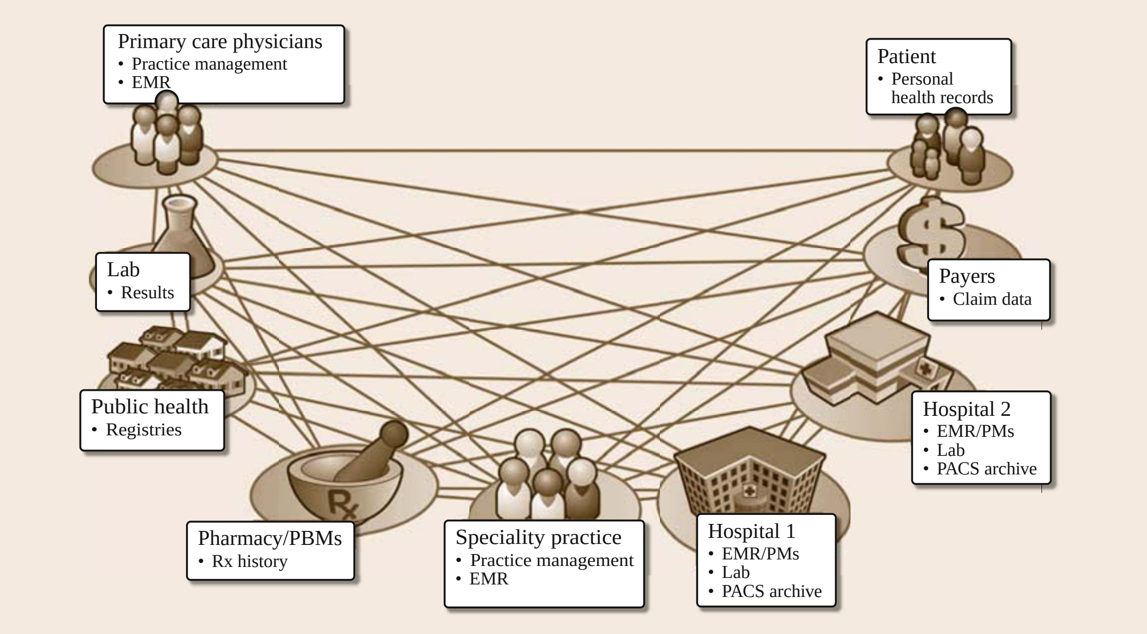

Fig. 77.11 Automation has a crucial role in how frequently a patient will interact with the healthcare system based on complexity of the experience and how a patient will retrieve healthcare information beyond the episodes of care

allow physicians and/or care managers to interact with populations of patients to manage specific diseases such as diabetes, asthma, and congestive heart failure. These application extend the clinical feature to include registries of patients with key clinical information to highlight which patients need help from the healthcare system and provide tools to enable collaboration with the patient on a shared plan of care for their diseases.

While these clinical applications tend to be provided by providers there is another class of wellness and disease management applications that are provided by insurers and employers. These applications share some of the same features described above but also include applications to inspire health behaviors in populations in consumers. These programs have been shown to reduce the costs of healthcare for employers and reduce the cost of managing populations for insurers.

Finally people are beginning to take more control of their own healthcare records and there has been an emergence of digital personal healthcare records (PHRs). These personal healthcare records allow people to record their key clinical information such as labs, diet, exercise, medication lists, etc. Some PHRs can connect to EMRs and directly share information between patients and providers. Some PHRs also include wellness and disease management features to link the patients personal data with activities that drive health and wellness. Although PHRs offer opportunities to empower patients, increase sharing and collaboration, and drive better health behaviors, their adoption remains low while commercial interest remains high.

77.3.6 Interoperability

Despite the successful digitization and automation of the workflows within many global locations, most information is stored in silos and is unable to provide maximum impact on patient care. Unfortunately, it's often at the same boundaries that prevents digital information flow from improving quality and safety reside. For example, when a patient is discharged from the hospital it is most common that medication changes and follow up plans are confused. It is also at discharge when a new set of healthcare providers will manage the patient and often these healthcare providers do not have a mechanism for accessing the digital patient record if it is present. Interoperability strategies seek to improve this flow of information. Within the US there are strategies to create regional health information organizations (RHIOs) that can manage the exchange of critical information across these institutional boundaries. At a national level there are plans to develop a National Health Information Network (NHIN) to connect these RHIOs. Unfortunately, even at an institutional level there are numerous clinical and financial applications that have difficultly communicating and thus there are significant unmet needs even within a single organization. Many countries across the globe are issuing tenders to seek solutions for health information exchange on national levels.

Putting aside the complex business model and organizational barriers that have been significant barriers towards significant national and local information exchange, there continues to be significant technology barriers. One of the fundamental challenges resides in the prime directive of medical informatics in that most systems store data rather than knowledge and as a result have no external references to establish the meaning of data that needs to be exchanged. For example, consider allergies. Allergies represent one of the most acute life threatening risks to an individual whenever he encounters a healthcare system, especially if he enters the system unconscious. Surprisingly, there is no common dictionary for allergies, and as a result most systems have no method to exchange allergies in a form beyond simple free text. With free text allergies there is no method to perform simple allergy checking before prescribing or administering a drug.

Today organization such as Health Language 7 (HL7), Integrating the Healthcare Enterprise (IHE), Healthcare Information Technology Standards Panel (HITSP), and the Center for Healthcare Information Technology are all working on establishing standards to facilitate interoperability across institutions and across vendors. Although there are emerging standards for rudimentary exchange of information today there are surprisingly few examples of information exchange even at the level we have come to expect in the banking industry. With patients continually changing healthcare environments due to changes in health and changes in insurance, the challenge of interoperability must be solved to ensure that information technology has a significant impact on the quality of care.

77.3.7 Enterprise Systems

Historically, patient access and financial systems were the first to gain a foothold in healthcare. Driven by the bottom line, these supported the back office and had no access to (or need for) clinical data. Clinical systems followed, designed to address specific needs in individual care areas such as labor and delivery, where there was a need to record and store the massive amounts of information generated by fetal heart monitors and other devices. For the past two decades, lab systems built around the workflow of technicians and pathologists have had the capability to collect results from a wide array of tests and present physicians with a single view of all the data for each patient (although in most physician's offices that information is still presented on paper rather than electronically).

Because these systems were developed for specific care areas, each tightly adhered to the workflow in one particular area. Many healthcare organizations adhered to a best-of-breed approach, buying a lab system from one vendor, a pharmacy system from another, a perioperative system from a third, and so on. These care area-specific systems can be more nimble, and can be installed in a matter of weeks, but require complex interfaces in order to share data with each other. As time passed, clinicians recognized the need for enterprise-wide systems, so some vendors of area-specific systems began broadening their scope.

Other vendors took the approach of developing enterprise-wide systems that allow information to easily cross the boundaries between care areas. Consider, for example, what happens when a physician orders medication for a hospital patient: the provider needs to know whether the patient is allergic to that drug, or has been given any other medication that should not be combined with the new one, formularies must be consulted to see whether the hospital is dispensing the drug and whether the patient's insurer will pay for it, the order must be transmitted to the hospital pharmacy, where the pharmacist double-checks the dose to make sure it is appropriate for the patient's age, weight, and condition. After the pharmacist dispenses the drug, it must be conveyed to the right location in the hospital, where a nurse will pick it up, administer it to the patient, and document the time of administration (perhaps using a barcode scanner to make sure the right patient is being given the right medication).

The trade-off for the easy flow of information across the enterprise is in specificity and implementation time. The best area-specific systems do one thing only, and do it better than the current generation of enterprise systems. Smaller, more discrete systems are also easier and faster to install. As the technology matures, however, we will see a convergence as enterprise systems acquire the greater depth of area-specific capabilities.

77.4 Conclusion

The practice of healthcare is incredibly complex generates massive amounts of mission critical data that must be assimilated and acted upon quickly. In many cases, the margins for error are slim and the costs of error immense. Information technology has the potential to transform the way we practice medicine by turning data into knowledge and knowledge into action. This will enable providers to deliver better quality care at lower cost, to maintain consistency of care for a given disease while appropriately tailoring care to each individual patient's unique condition and genetic makeup, and to localize the application of care guidelines based on knowledge about specific populations of patients.

Some of the tools to accomplish these goals exist today, but they need to be modified or adapted to suit the unique demands of healthcare. We have systems that can alert clinicians to potential errors, for example, but these systems must be fine-tuned to prevent alert fatigue. Other challenges, such as interoperability, which enables data sharing among systems from different vendors, remain largely unanswered at the moment.

78. Medical Automation and Robotics

Alon Wolf, Moshe Shoham

Robotic systems that are integrated in medical applications are designed to help and assist rather than injure a human being, whether it is the patient or the operator. This chapter presents the classification of medical robots as passive, semiactive, active, remote manipulators, and navigators. The kinematic structure of medical robots is discussed next, as are the fundamental requirements from medical robots. Finally, the main advantages and emerging trends in medical robotics are given.

> *1. A robot may not injure a human being or, through inaction, allow a human being to come to harm.*
> *2. A robot must obey orders given to it by human beings except where such orders would conflict with the First Law.*
> *3. A robot must protect its own existence as long as such protection does not conflict with the First or Second Law.*

Written almost 65 years ago, these three laws of robotics by the famous science fiction author Issac Asimov (*Runaround*, 1942) are still very relevant and serve, though not literally, as guidelines for the field of medical automation and robotics. By definition, robotic systems that are integrated in medical applications are designed to help and assist rather than injure a human being, whether it is the patient or the operator. Many precautions (more than one would find in nonmedical robotic systems) are being taken to ensure the safety of patients and operators. As presented in this chapter, these safety measures include, among others, dual backup systems, as a minimum, and fail-safe systems. These redundant systems are there to prevent unwanted motions that may harm the patient or the staff, to assure accurate performance of the task, and also to protect the robot itself as stated in the third law of robotics.

As elaborated in this chapter, current medical robotic systems are divided into three categories, mainly reflecting level of autonomy. The most popular and widely implemented method is teleoperation, where the robotic system follows the operator's (surgeon's) hand motions from an offsite control console that can be located either in the operating room or even somewhere overseas using fast communication lines. In this mode of operation, the robot, just like in Asimov's second law, obeys and follows the operator's commands and motions. These systems are capable of filtering tremors in the surgeon's hand movements (crucial in neurosurgery and ophthalmic surgery), scaling down the operator's motions and forces, and at the same time preventing unwanted motions that could harm the patient (the active constraint concept).

The first swallows of medical robots appeared in the mid 1980s and early 1990s with the implementation of the Puma 560 for stereotactic neurosurgery. The application was a computed tomography (CT)-guided needle steering system for brain biopsy. Then came ROBODOC from Integrated Surgical Systems in 1992. ROBODOC milled out precise fittings in the femur for hip replacement surgery. ROBODOC was a pioneering surgical active robot that paved the way for other robotic systems, mainly remotely manipulated, semiactive, and active constraint robots. Current surgical applications are in the fields of gastrointestinal surgery, urology, gynecology, cardiothoracic surgery, oncology, orthopedic surgery, and neurosurgery.

Despite more than two decades of research in the field of medical robots, it seems that this field has not yet reached maturity and is still in its infancy. Nevertheless this fact does not prevent researchers from thinking of the next step, i. e., integration of computer-assisted surgery (CAS) devices into one complete system. This is called the operating room of the future (ORF). This initiative is crucial in light of the increasingly growing number of surgical instruments, monitoring and imaging devices, information systems, and communication networks used in modern operating rooms and interventional suites. See also Chap. 82 on *Computer- and Robot-Assisted Medical Interventions*.

78.1 Classification of Medical Robotics Systems

Medical robots have been classified in the literature according to the following categories: remote manipulators, and passive, semiactive, and active robots, by *Cinquin* [78.1], *Stulberg* [78.2], *Taylor* [78.3, 4], *Troccaz* [78.5], *Bainville* [78.6], and *Nolte* [78.7].

Since this area of research is very dynamic and, in our opinion, has not yet reached maturity, it is likely that categories and classifications that are widespread today will change over time, with the evolution of new concepts. Nevertheless, we present in this chapter a brief overview of current leading technologies and trends in the field of medical robotics. For an extensive review of the literature and classification of existing medical robotic system we refer readers to [78.8–10].

Finally, we also present the major considerations to be taken into account in the design of new medical robotic systems.

78.1.1 Passive Medical Robotic Systems

Passive medical robotic systems support the surgical procedure, but take no active part during surgery. In other words, the surgeon is in full control of the surgical procedure at all times, i. e., the actual surgical procedure is conducted by the surgeon. Early versions of Arthrobot [78.11] fall into this category of passive systems. In early stages, the robot was used as an assistant in the operating room to hold the patient's limb during joint replacements of knees and hips. Arthrobot had no sensing capabilities and was able to move only under explicit human control. Today, one of the main forms of passive medical robotics is active constraint robotic systems. Acrobot [78.12] is an example of an active constraint passive robotic system. Developed by *Davies* et al. [78.13–15], its core proprietary technology centers on the development of a new type of robotic control: active constraint robotics for orthopedic surgery. This concept facilitates synergy between the surgeon and the robot, provides active assistance to the surgeon, and prevents surgical errors. The surgeon guides the surgical tool that is attached to the robot with a handle with a force sensor attached to the robot tip, and thus uses his/her superior human senses and understanding of the overall situation to perform the surgery. The robot provides precise geometric accuracy and increases the safety by means of a predefined three-dimensional (3-D) motion constraint that prevents cutting outside a predefined safe region. This approach, known as *hands-on robotics*, keeps the surgeon in the control loop throughout the surgery. Moreover, the robot is guided by preoperative image-based planning software. This image-based software uses a patient's CT data to facilitate precise planning of the surgery, allowing implant selection and optimal positioning within the joint.

Another passive robot utilizing the active constraint concept is the MAKO robot, a haptic robotic sys-

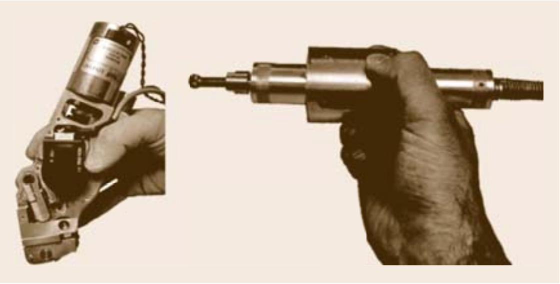

Fig. 78.1 Freehand sculptor by BlueBelt

tem that adds the sense of touch to a robotic-assisted surgical platform. The MAKO Haptic Guidance System is a Food and Drug Administration (FDA)-cleared, surgeon-interactive robotic system that enables the orthopedic surgeon to plan the alignment and placement of knee resurfacing implants preoperatively and make intraoperative bone-conserving cuts accurately within the safe workspace limited by the robot.

The precision freehand sculptor (PFS) by BlueBelt is a handheld tool to assist the surgeon in accurately cutting these shapes (Fig. 78.1). Its rotating cutter only allows the surgeon to remove waste bone; the cutter in turn retracts when it hits *good* bone (i. e., bone that is not supposed to be machined). Thus the surgeon can use the PFS freehand while it automatically restricts the cut to the proper shape [78.16]. This mode of operation is a modification of the active constraint concept. Instead of preventing hand motion, the system automatically and actively prevents cutting.

78.1.2 Semiactive Medical Robotic Systems

The semiactive category is presented in [78.17]. In this research a robot acts as an assistant during the operation by holding a tool in a steady position to allow accurate guidance of surgical tools. Other more up-to-date examples of semiactive systems are the NeuroMate (Integrated Surgical Systems, USA) and PathFinder (Armstrong HealthCare Ltd., UK). They provide guidance of the surgical tool but the actual surgical operation is conducted by the surgeon.

One of the very first applications of robotic systems in a surgical theater was positioning of a needle for stereotactic neurosurgery [78.18]. This application involves placement of a needle in a very accurate manner in a predefined location in a percutaneous approach (later used as a semiactive system). Further development of this approach is described in [78.19].

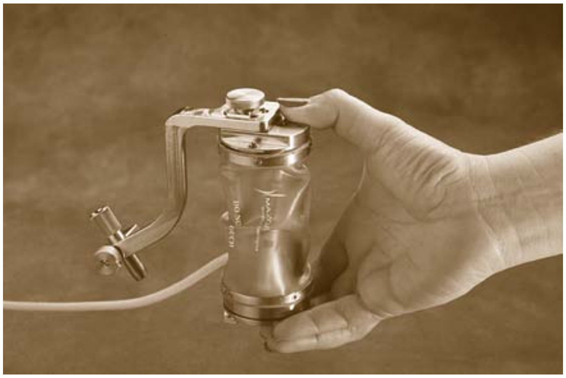

Fig. 78.2 Mazor's SpineAssist miniature robot for spine surgery

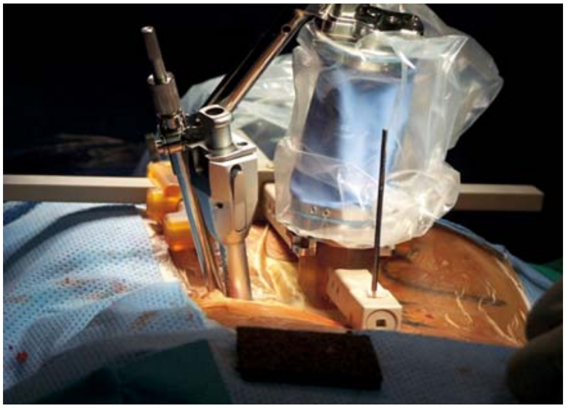

Fig. 78.3 SpineAssist during surgery

A different concept of a semiactive robot had been developed at the Robotics Laboratory at the Technion–Israel Institute of Technology and is manufactured and marketed by Mazor Surgical Technologies [78.20]. Mazor's SpineAssist (Figs. 78.2 and 78.3) is a 2 × 4 inch, 250 g, image-based robot designed to guide the surgeon to precise locations along the patient's spine according to a preoperative plan. Its small size and light weight allows mounting the robot directly on the patient's back, thus overcoming the patient's motion relative to the robot base and as a result improving the accuracy of the operation. The FDA- and Council Europe (CE)-approved SpineAssist robot has performed hundreds of cases and implanted thousands of screws with better clinical outcome than the freehand approach while at the same time allowing a minimally invasive approach.

PiGalileo is another bone-mounted guiding system. Just like in the case of SpineAssist, the actual surgical operations done with PiGalileo are still performed by a surgeon, with the electromechanical positioning device aiding the surgeon in instrument positioning. This technology is completely under the surgeon's control at all times, providing valuable intraoperative feedback to the surgeon to help improve precision, thereby potentially leading to better implant alignment and positioning.

78.1.3 Active Medical Robotic Systems

Active robotic systems perform surgical tasks, such as drilling or milling, autonomously with no direct intervention of the surgeon [78.21–23]. This group includes

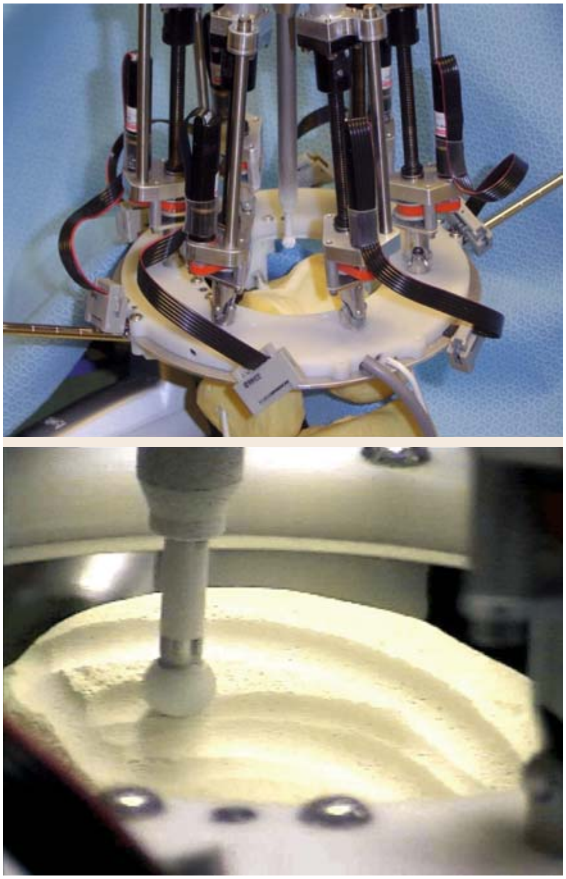

Fig. 78.4 MBARS used for joint arthroplasty

active robots such as RoboDoc, CASPAR, and MBARS. Perhaps one of the most famous active robots today is RoboDoc (Integrated Surgical Systems), developed by *Paul* et al. [78.24, 25]. The system was originally used for total hip replacement procedures, yet was later modified for use in total knee replacement procedures (today it is less used because of controversy over long-term clinical effectiveness).

MBARS (Fig. 78.4) is an active version of the bone-mounted robotic system concept. Although this is still an academic study, the system demonstrates the capability to actively prepare the bone cavity for an implant during joint arthroplasty procedures.

The robot is composed of six linear actuators that are connected in parallel between two rigid platforms: the lower reference platform and the upper platform, which is the moving end-effector of the robot. This structure is known as the classical Stewart–Gough six-degree-of-freedom robot. The robot is attached to the femur by three pins: one pin is inserted into the medial epicondyle, one into the lateral epicondyle, and one into the metadiaphyseal region of the femur. A rigid connection of the robot to the operated bone is obtained through these three pins. The robot is equipped with a milling device, which actively mills the bone according to the preoperative plan.

The CyberKnife robotic radiosurgery by Accuracy System is a radiosurgery system designed to treat tumors anywhere in the body with high accuracy. Using image-guidance technology and computer-controlled robotics, the CyberKnife system is designed to track the tumor continuously, detect its location, and correct for tumor and patient movement in real time throughout the treatment. Because of its extreme precision, the CyberKnife system does not require invasive head or body frames to stabilize patient movement, vastly increasing the system's flexibility.

Gamma Knife PERFEXION is Elekta's new Leksell system for stereotactic radiosurgery in the brain, cervical spine, and head and neck regions. The Leksell Gamma Knife PERFEXION expands treatment reach, offering a wider range of treatable anatomical structure. This expanded anatomical treatment area offers dramatic new opportunities to increase patient volume. Leksell Gamma Knife PERFEXION makes the entire procedure more efficient and user-friendly. Collimator changes can be made by the control program, optimizing the workflow and significantly reducing treatment time.

78.1.4 Remote Manipulators

Perhaps the most commonly used medical robots today are remote manipulators. Remote manipulators are robotic system that can be operated from a remote location. In other words, the surgeon does not have to be at the bedside, nor even in the operating room, and yet can still perform the surgical procedure using the robotic system, which serves as his hands and eyes.

Remote manipulators are robotic systems that can be operated from a remote location. Medical procedures utilizing this mode of operation are often named telesurgery. The first concept was developed at Stanford Research Center as a project for the US Army. The concept of telesurgery was first demonstrated in 2001, when an expert surgeon removed the gallbladder of a 68-year-old patient. This looks like a very common procedure that is done on a daily basis in many locations around the world, with one exception: the patient was operated on in Strasbourg, France and the surgeon operated

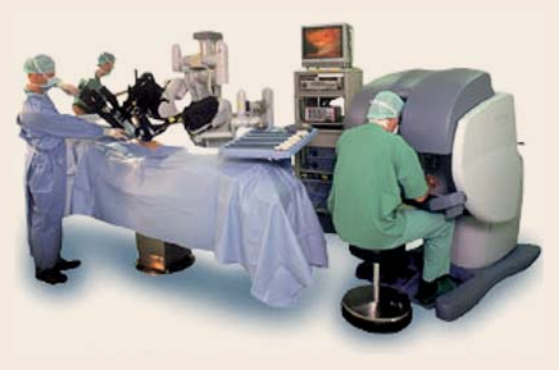

Fig. 78.5 Da Vinci system

from New York. For successful performance of such a telesurgery, a high-speed computer connected through a reliable high-speed network is required. This successful demonstration has opened new horizons of surgical procedures performed worldwide with experts sitting in communication centers. Telesurgery can bring experts to places where there are scarce medical facilities and medical professionals, such as third-world countries and war zones.

Although the first telesurgery was carried out only in 2001, telesurgical systems were introduced earlier. Computer Motion (now Intuitive Surgical Inc., USA) introduced in 1994 the AESOP system. This robotic system was used to manipulate a camera during laparoscopic surgery. Overall, about 70 000 surgeries were performed worldwide using this system. Once acquired by Intuitive, the AESOP system was not sold anymore. Instead, Intuitive Surgical Inc. introduced the Da Vinci medical robot. During surgery, the surgeon operates the robot from a remote console using a specially design control mechanism and a stereo vision system. In April 2005, the Da Vinci system (Fig. 78.5) was approved by the FDA to perform gynecological procedures, although it is used for other procedures as well, such as urologic, general laparoscopic, noncardiovascular, thoracoscopic, and others.

Although Intuitive Surgical is a world leader in the development of robotic technology of minimally invasive surgery (MIS) with its Da Vinci robot, it is worth mentioning another medical robot that competes with the Da Vinci system for the same market. Computer Motion (now owned by Intuitive Surgical) introduced the Zeus system (Fig. 78.6). Just like the Da Vinci system, Zeus is composed of multiple robotic arms capable of manipulating MIS tools and visualization equipment for cardiac surgery.

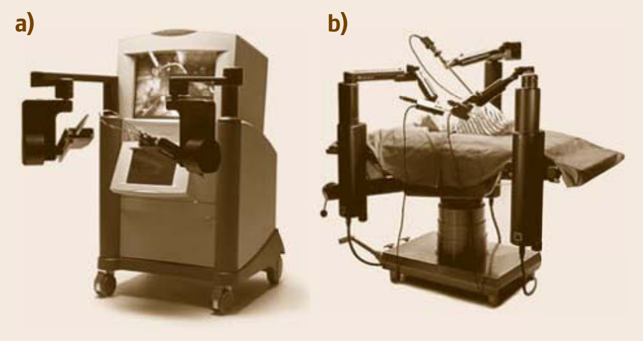

Fig. 78.6a,b Zeus system: (a) console, and (b) robot arms

On 5 April 2001 a 63-year-old male patient underwent multivessel off-pump coronary artery bypass surgery at the University of Pittsburgh Medical Center (UPMC) Presbyterian Hospital using the Zeus system. This was the first time ever that such a procedure was carried out. Marco A. Zenati from the UPMC Department of Surgery operated the robot while seated at a console about 10 feet from the patient. The robot was equipped with an endoscope, which was manipulated by one of the robotic arms using voice commands, while at the same time the other two arms were controlled by operating handles that resemble conventional surgical instruments.

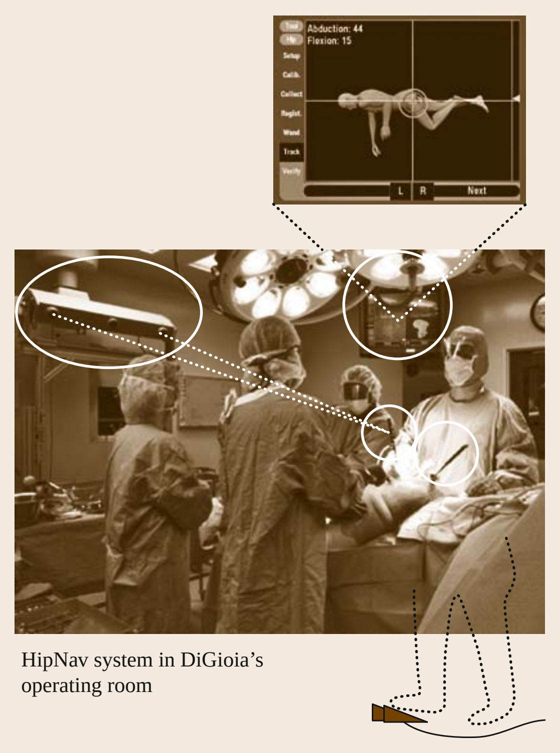
78.1.5 Navigators

Surgical navigators are the central element in many medical robotic system [78.26]. They come into play during the registration procedure. Registration is a crucial and necessary procedure, during which each part of the medical system is synchronized. Most medical robotic systems include preoperative (sometimes intraoperative) planning of the medical procedure. During this step, a virtual surgery can be performed and simulated on a computer screen (just like with any computer-aided design system). The data provided to the surgeon is patient specific and is usually based on a preoperative CT or magnetic resonance imaging (MRI) scan. The end result of this procedure is the transformation that maps the anatomical position in the operating room to its preoperative CT/MRI-based model. One example of a method for achieving this transformation is minimization of the pointwise distance between a cluster of anatomical points collected intraoperatively and points on the preoperative surface model. The coordinates of anatomical points are acquired by touching points on the patient's anatomy (anatomical landmarks) using an optically tracked probe [78.27]. It is sometimes easier to think of these systems as global positioning systems (GPSs) for the operating room. The basic concept of a surgical navigation system is to ascertain the position, i. e., the location and orientation, of the relevant components of the system and the patient's anatomy in a global coordinate system such that their relative position can be determined. During surgery, the position coordinates provide precise guidance to the surgeon to perform a preplanned procedure.

In 1974, *Schlondorff* et al. [78.28] developed one of the first systems for navigational calculations involving bone. The system used a radiographic centimeter scale held between the patient's teeth during a lateral roentgenogram. The measurements enabled the calculation of the distances between several anatomical points. Later, *Watanabe* et al. [78.29] from Siemens Corporation published their work on the first model of the Neuronavigator, a mechanical device based on a multijoint 3-D digitizer. The device is used to track the tip of the sensor arm by indicating its location on preoperative CT or MRI images.

One of the first systems to use an optical-based navigation technique was HipNav (Fig. 78.7), developed at Carnegie Mellon University in Pittsburgh, PA (USA) by *DiGioia* and *Jaramaz* [78.30]. The system was the first computer-assisted navigation system for cup placement in total hip replacement (THR) surgery. Beside its significant clinical contribution, this has set the standard for preoperative planning and range-of-motion (ROM) simulations for THR. HipNav incorporated information provided to it by the OptoTrak system by Northern Digital Inc., Waterloo, Ontario. The OptoTrak system is composed of three charge-coupled device (CCD) cameras contained in a rigid enclosure and a set of active trackers, where the body of each tracker incorporates a set of light-emitting diodes (LEDs) mounted at precise relative positions, and the position of each tracker can be resolved in the OptoTrak coordinate system. For the HipNav system, the trackers were fixed to tools, implants, and the patient's bones, enabling active tracking of their positions during operative procedures. Since HipNav, there have been other systems that employ this type of technology, including the VectorVision, SurgiGATE, Navitrack, StealthStation, Stryker, and Surgetic systems.

A new version of medical navigators is the image overlay concept (Fig. 78.8). Image overlay is a computer display technique that superimposes computer images over the viewer's direct view of the real world [78.31]. In other words, it is a form of *augmented reality* in that it merges computer-generated information with real-world images by the projection of virtual objects in real scene. To do this the system needs to project the virtual image onto some sort of screen. The most common measure used is a semitransparent display device (like a heads-up display in fighter planes), which allows both viewing the real objects while at the same time overlaying the virtual image on them. For example, a 3-D image of a bone, reconstructed from CT data, can be displayed to a surgeon inside the patient's anatomy at the exact location of the real bone, regardless of the position of either the surgeon or the patient (Fig. 78.8), creating an elusion of an image which appears to the viewer to be inside the real objects. To do this in a *convincing* yet accurate way, the positions of the viewer's head, objects in the environment, and components of the display system are all tracked in space. These positions are used to transform the images so that they appear to be an integral part of the real-world environment.



HipNav system in DiGioia's operating room

Fig. 78.7 HipNav system

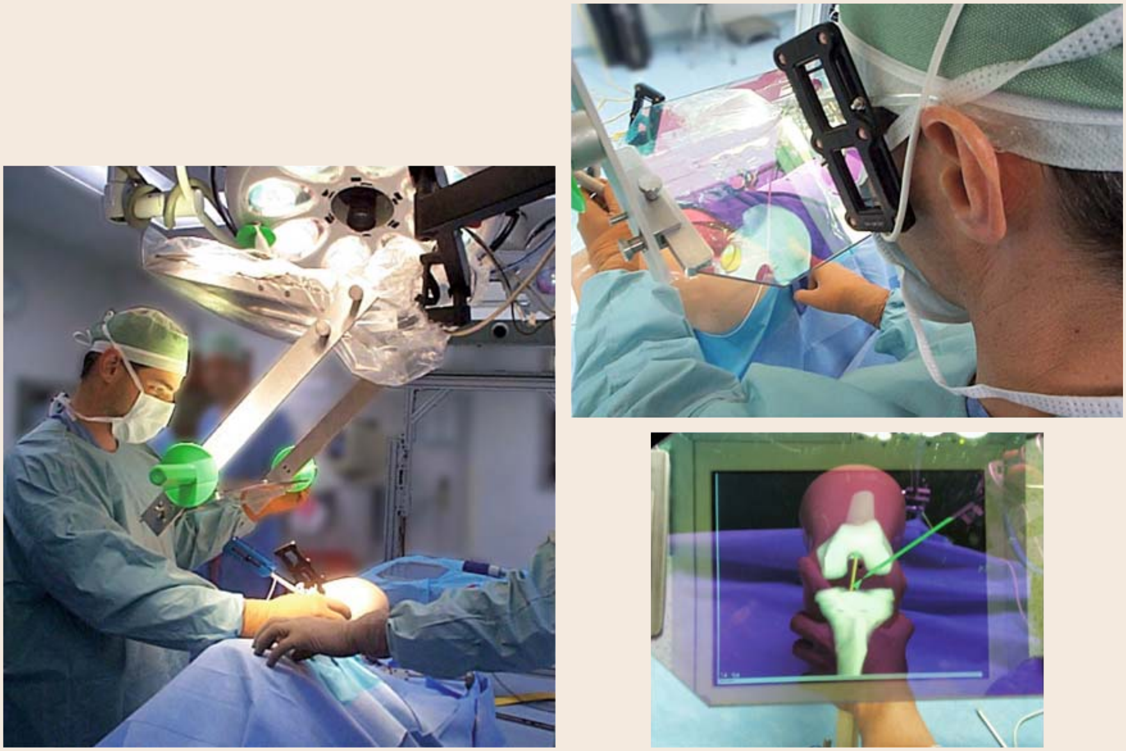


Fig. 78.8 Image overlay

This technology has many clinical applications; one of the most common is needle steering, i. e., manipulating a real/virtual needle into remote unexposed organs for biopsy, drug delivery, and interventions.

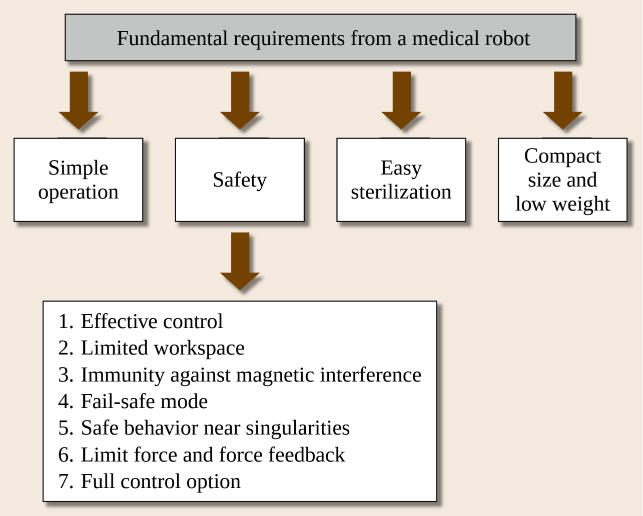
78.2 Kinematic Structure of Medical Robots

In most up-to-date medical robotic systems, a serial robot is used as a surgical assistant. These robots suffer from numerous drawbacks related to the serial manipulator, such as low rigidity and accuracy. The fact that theses robots are integrated in medical procedures, where accuracy and safety is a matter of life and death, has led researchers to look for better manipulators suited for a specific surgical task or field of tasks. A family of robots found suitable for medical application is parallel robotic mechanisms. *Grace* and *Brandt* [78.32, 33] stressed the advantages of parallel manipulators compared with serial manipulators in surgical operations, mainly due to their low weight, compact structure, better accuracy, stiffness, restricted workspace, and low price. However, parallel manipulators have some drawbacks. One of the main disadvantages of parallel robots is their limited workspace. Nevertheless, limited workspace can be considered as an advantage in medical applications where the required workspace is itself very limited. This attribute limits the potential placement positions of the robot in the operating room (OR), since the parallel robot has to be positioned very close to the operating area in order to be able to perform a surgical task within its limited workspace. In most cases, this requirement is not feasible due to physical conditions in the OR. One of the tested solutions has been designed with the entire robotics system attached to the OR ceiling so that the robot works *upside down*, as proposed for example in Fig. 78.5. In this way, the robot does not interfere with the surgical procedure, and is activated and maneuvered to the operating area when required.

78.3 Fundamental Requirements from a Medical Robot

The fundamental requirements from a medical robot for surgery tasks were introduced in [78.35], where the authors stressed the safety requirements (Fig. 78.9):

1. *Effective control.* Both force and speed control of the end-effector should be allowed or limited by hardware in all robot configurations.
2. *Workspace.* The robot workspace has to be limited to the effective area of the operation, to prevent accidental damage both to the physician and to the patient.
3. *Limited forces or force feedback.* The force applied by the robot during procedures where the robot takes active tasks and is in contact with live tissue must be fully controlled. Moreover, in procedures where different levels of force are applied (such as bone cutting [78.36]), the physician needs as much data as possible from the robot concerning the force applied.
4. *Full control option.* In procedures where the robot automatically performs a surgical procedure, the physician has to be able to take over control of the robot at any stage during the operation.
5. *Fail-safe features.* In the event of a malfunction in the robot, the system has to switch to a fail-safe mode; for instance, in case of a power failure, the robot has to remain in its current location until power is restored.
6. *Singularity behavior.* The robot path planning must avoid passing near singular configurations, or actively prevent the surgeon from driving the robot through singular configurations, if any, or designed in such a way that all singular poses of the robot are outside the operating work envelope.
7. *Sterilizability.* The robot structure must allow sterilization, or be protected with a suitable cover.
8. Immunity against magnetic interference of other surgical tools available in the OR.



Fundamental requirements from a medical robot
Simple operation
Safety
Easy sterilization
Compact size and low weight
1. Effective control
2. Limited workspace
3. Immunity against magnetic interference
4. Fail-safe mode
5. Safe behavior near singularities
6. Limit force and force feedback
7. Full control option

Fig. 78.9 The fundamental requirements from a medical robot [78.34]

78.4 Main Advantages of Medical Robotic Systems

Several researchers have investigated the advantages of robotic systems in surgery. *Kazanzides* et al. [78.37] compared the cross-section of manually broached implant cavities to cavities milled by robots in hip replacement surgery. The results of this research have illustrated the robot's precision compared with the precision of the human hand. *Kavoussi* et al. [78.38] compared the performance of a human to that of a robot assistant in manipulating the laparoscope. The results of this research emphasize the superiority of the robot compared with the human hand in terms of steadiness. *Cameron* and *Pradeep* [78.39] measured the accuracy of the human hand of four skilled eye surgeons. The results stressed the tremor and inaccuracy of the human hand, even for skilled surgeons. An average root-mean-square (RMS) error of 49 μm was obtained when asked to hold an instrument steady, and 133 μm for repeated actuation. *Cameron* et al. [78.40] presented a robotic prototype that incorporates sensing and actuation, reporting accuracy of 5 μm and better for a robotic system holding an ophthalmologic microsurgical instrument, representing a significant improvement with respect to those presented in the first article [78.39]. These results indicate that the combination of advanced medicine with high-technology research capabilities can improve many surgical procedures that are currently performed manually and are limited by restricted accessibility and the lack of preciseness of the human hand. Areas which have been identified as appropriate at this stage include orthopedic surgery, cutting and joining of bones at exact optimal location, laparoscopic surgical procedures, and accurate maneuvering of laparoscopic camera and tools in a constrained environment.

In light of this, the advantages of using a medical robotic system can be divided into two categories: those related to the benefits to the surgeon and those related to the benefits to the patient when using robotic technology. Medical robotics enable the surgeon to perform new percutaneous procedures that could not have been executed before, improve the surgeon's ergonomics, enhance the surgical result (MIS), shorten the surgical procedure, reduce radiation exposure, provide better image visualization, and enable extension of the operation theater to remote locations using telesurgery techniques. For the patient, there are few advantages due to the use of medical robotic technology during the procedure, mainly since the surgical procedure is performed minimally invasively. This results in faster recovery time, less pain, less postoperative complications, better cosmetic results, and cost reduction.

78.5 Emerging Trends in Medical Robotics Systems

Robots complement the trend in surgical procedures toward minimal invasiveness. Robots serve as remote hands for the surgeon and can deliver his/her motions to the patient through miniature incisions. In order to be able to mimic the surgeon's hand adequately and even achieve superiority in terms of accuracy and miniature motions, it is important to integrate force feedback capabilities into the system as well as tactile feedback. However today even the best systems still suffer from inaccurate forces and insufficient tactile feedback, which are essential in several medical procedures. Hence, this is an area for future research and development.

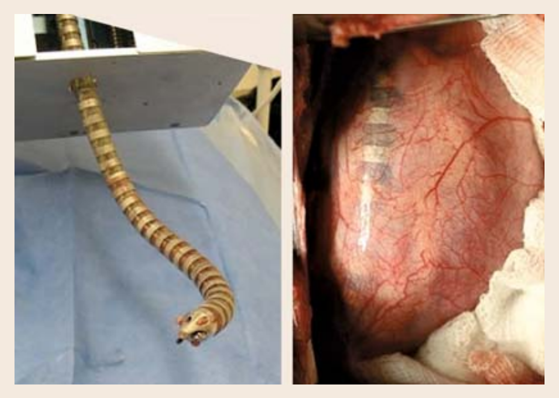


Fig. 78.10 CardioArm – a hyper redundant snake like robot for cardiac surgery

Making medical robots more friendly and intuitive is essential for the introduction of robots into operating rooms. One of the lessons that robot developers can learn from the two decades of application of surgical robots is that it is of utmost importance to make robots friendlier to the operating-room environment. Moreover, even though the technology is here, almost no new surgical procedures have been developed based on robotic technology that cannot be performed otherwise. It is therefore expected that, in order to penetrate the operating-room environment, new surgical technologies have to be developed based on robotic technology, and even more importantly, robots must become much more friendly to this unique atmosphere.

An even more intriguing approach to medical robots is miniature robots that can move inside the human body (Fig. 78.10). Several laboratories around the world are pursuing this research with very few (like the passive Given Imaging's pillCam) in clinical use.

The area of medical robots is still in its infancy, with applications with great potential not yet explored. The trends are surgical robots with high accuracy, robotically operated minimally invasive approaches, miniature robots that move inside the human body, and rehabilitation robotics.

79. Rotary Heart Assist Devices

Marwan A. Simaan

The left ventricular assist device (LVAD) is a mechanical device implanted in patients with congestive heart failure to assist the heart in pumping blood through the circulatory system. The latest generation of this device is comprised of a rotary pump which is generally much smaller, lighter, and quieter than the first-generation conventional pulsatile-type pump. The rotary pump is controlled by varying the rotor (or impeller) speed to adjust the amount of blood flow through the LVAD. If the patient is in a health care facility, the pump speed can be adjusted manually by a trained clinician to meet the patient's blood needs. However, an important challenge facing the increased use of these devices is the desire to allow the patient to return home. The development of an appropriate feedback controller that is capable of automatically adjusting the pump speed is therefore a crucial step in meeting this challenge. In addition to being able to adapt to changes in the patient's daily activities by automatically regulating the pump speed, the controller must also be able to prevent the occurrence of excessive pumping. This dangerous phenomenon, known as suction, may cause collapse of the ventricle and damage to the heart muscle. In order to be able to develop such a controller based on modern control theory an appropriate mathematical model of a combined cardiovascular system and LVAD must first be developed. In this chapter, we develop such a model. The model is dynamic, time-varying, and consists of six coupled nonlinear differential equations. The time variation occurs over four consecutive intervals representing the contraction, ejection, relaxation, and filling phases of the left ventricle. The LVAD in the model along with its inlet and outlet cannulae are represented by a nonlinear differential equation which relates the pump rotational speed and pump flow to the pressure difference across the pump. Suction is accounted for by adding a nonlinear resistance in the LVAD model when the pressure in the left ventricle drops below a specified threshold. Using this model we discuss some of the challenges faced in the development of: (1) an appropriate feedback controller for the LVAD, and (2) an effective algorithm for detection of suction in the left ventricle.

Heart transplantation has now been recognized as the best therapy for patients with end-stage congestive heart failure. However, potential recipients often wait long periods of time (300 days or more on the average) before a suitable donor heart becomes available, and many of these candidates, 20–30%, will die while awaiting heart transplantation. Consequently, the medical community has placed increased emphasis on the use of mechanical circulatory assist devices that can substitute for, or enhance, the function of the natural heart while the patient is waiting for the heart transplant [79.1, 2]. A left ventricular assist device (LVAD) is such a device. There are two different types of LVADs. The first is a pulsatile pump producing pulsatile pressures and flows similar to those produced by the natural heart. The second, and more recent, is a rotary pump that operates continuously attempting to draw blood out of the left ventricle and into the circulation. Rotary pumps are typically, quieter, smaller, and more efficient than pulsatile pumps, and consequently have received considerable acceptance in recent years. Generally speaking, the goal of the LVAD is to assist the native heart in pumping blood so as to provide the patient with as close to a normal lifestyle as possible until a donor heart becomes available or, in some cases, until the patient's heart recovers. In many situations, this means allowing the patient to return home and/or to the workforce.

An important engineering challenge facing the increased use of the rotary LVAD is the development of an appropriate controller for the speed of the rotor (or pump impeller). Such a controller, in addition to being robust and reliable, must be able to adapt to the daily activities and physiological changes of the patient by regulating the pump speed in order to meet the body's requirements for cardiac output (CO) and mean arterial pressure (MAP) [79.3, 4]. Since the rotary pump does not use valves, if its speed is too low, blood may regurgitate back from the aorta to the left ventricle through the pump, resulting in what is known as *backflow*. If the pump speed is too high, the pump will attempt to draw more blood from the ventricle than available, which may cause collapse of the ventricle resulting in a dangerous phenomenon called *suction*. The occurrence of suction must be detected quickly and the pump speed reduced before the heart muscle is damaged. While avoiding these two extremes, the pump speed must also be adjusted continuously, up and down to meet the patient's varying levels of physical activity and emotional changes [79.5–10]. The eventual goal of a pump speed controller is therefore to meet all these requirements so that an LVAD recipient patient could potentially leave the hospital and return home to a normal lifestyle. Given that the pump is continuously interacting with the cardiovascular system, the development of a speed controller that meets the above objectives must therefore be done using tools developed in modern control theory. This cannot be done without first having an appropriate mathematical model for this complex system. The model must be simple enough to be tractable and yet it must be comprehensive enough to capture the essential relationships between the hemodynamic variables and provide the important input and output boundary conditions without the ambiguity of unnecessary state variables. In this chapter, we discuss the development of such a model. We first present and validate an autonomous fifth-order model of the cardiovascular system which emphasizes the pressure–volume relationship of the left ventricle. We then present a first-order model of a rotary LVAD along with its inlet and outlet cannulae and with the pump rotational speed as its control variable. We account for the phenomenon of suction by adding a nonlinear resistance to the inlet cannula model which becomes active when the left ventricular pressure drops below a certain threshold. Finally, we combine these two models into a sixth-order time-varying nonlinear model with the rotational speed of the pump being the only control variable. The time variations in this model are due to the cyclical nature of the ventricle elastance and its changes as a function of time within one cardiac cycle. The nonlinearities are due to the mitral and aortic valves in the cardiovascular model and the suction resistance in the LVAD model. The binary state of each of these valves yield four consecutive phases within one cardiac cycle during which the ventricle contracts, ejects, relaxes, and then fills depending on which valve is open and which is closed. As a result, the mathematical description of the entire model changes as the ventricle crosses from one phase to the next. We will conclude this chapter by outlining some of the challenges in the development of both a feedback speed controller and a suction detection algorithm that need to be overcome before the ultimate goal of the LVAD becomes a reality and LVAD patients are able to return to a normal lifestyle.

79.1 The Cardiovascular Model

A cross-section schematic of the heart illustrating its various components is shown in Fig. 79.1. Each side of the heart has its own atrium and ventricle, and each side controls a different blood circulation path. The left side of the heart controls the systemic circulation of blood throughout the body while the right side controls the pulmonary circulation of blood to the lungs [79.11]. After the blood picks up oxygen in the lungs it returns to the heart entering through the left atrium. The left ventricle pumps the oxygen-rich blood through the aorta to the rest of the body. The blood returns to the heart depleted of oxygen, this time through the right atrium. It

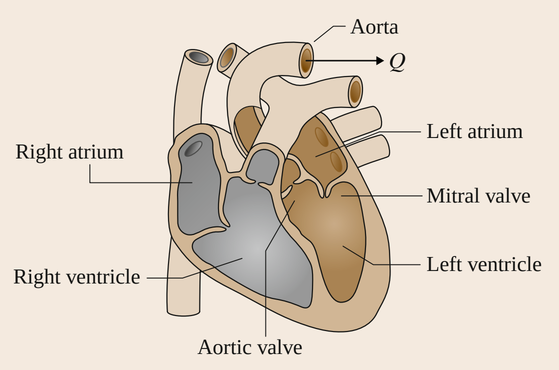

Fig. 79.1 Cross-section of a beating heart

is then pumped to the lungs by the right ventricle. The blood receives oxygen in the lungs, and returns to the left atrium of the heart. Upon entering the left atrium, the two circulatory paths are then repeated. The blood path through the heart and both circulation systems can be seen in Fig. 79.2 [79.12]. Due to the different nature of the two circulation paths, each side of the heart has a different workload. The systemic circulation is much longer than the pulmonary one, and encounters considerable more resistance [79.11]. To handle the longer path, the left ventricle is more elastic than the right, giving it the strength to pump blood at a higher pressure.

The heart is a very complex system that is very difficult to model mathematically. Numerous dynamical state-space models of varying degrees of complexity have been developed in the past fifteen years or so. For example, an eighth-order hybrid model of the heart which subdivides the human circulatory system into a number of lumped parameter blocks that include the pulmonary arterial and venous systems as well as both ventricles has been developed in [79.13]. An 11th-order model which includes the resistance of peripheral blood vessels has been developed in [79.14]. Although a complete heart model can be supplemented with a model of an LVAD, in this chapter we assume that the right ventricle and pulmonary circulation are healthy and normal and as a result their effect on the LVAD, which is connected from the left ventricle to the ascending aorta, can be neglected [79.1, 6]. A fifth-order lumped parameter electric circuit model which can reproduce the left ventricle hemodynamics of the heart [79.15, 16] is shown in Fig. 79.3. In this model, the behavior of the left ventricle is modeled by means of a time-varying capacitance (or compliance) $C(t)$, which is the reciprocal of the ventricle's elastance function $E(t)$. The elastance represents the contractual state of the left ventricle. It relates to the ventricle's pressure and volume [79.17] according to an expression of the form

$$E(t) = \frac{\mathrm{LVP}(t)}{\mathrm{LVV}(t) - V_0} , \tag{79.1}$$

where $\mathrm{LVP}(t)$ is the left ventricular pressure, $\mathrm{LVV}(t)$ is the left ventricular volume, and V_0 is a reference volume, which corresponds to the theoretical volume in the ventricle at zero pressure. Several mathematical expressions have been derived to approximate the elastance function $E_\mathrm{H}(t)$ of a healthy heart. In our work, we use the expression

$$E_\mathrm{H}(t) = (E_\mathrm{max} - E_\mathrm{min}) E_\mathrm{n}(t_\mathrm{n}) + E_\mathrm{min} , \tag{79.2}$$

Key:
🟥 Oxygen rich, CO2-poor blood
🟦 Oxygen poor, CO2-rich blood

Fig. 79.2 Diagram of systemic and pulmonary circulatory systems (after [79.12])

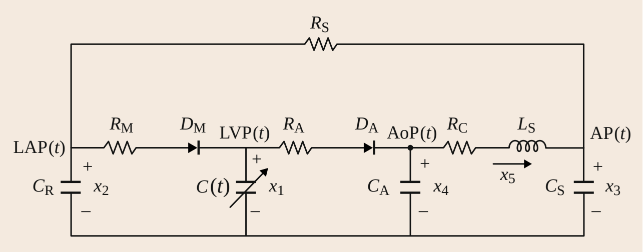

Fig. 79.3 Cardiovascular circuit model

where $E_n(t_n)$ is the so-called *double hill* function represented by the expression [79.18]

$$E_n(t_n) = 1.55 \left(\frac{\left(\frac{t_n}{0.7}\right)^{1.9}}{1+\left(\frac{t_n}{0.7}\right)^{1.9}} \right) \left(\frac{1}{1+\left(\frac{t_n}{1.17}\right)^{21.9}} \right) . \tag{79.3}$$

In the above expression, $E_n(t_n)$ is the normalized elastance, $t_n = t/T_{max}$, $T_{max} = 0.2 + 0.15 t_c$, and t_c is the cardiac cycle interval, i. e., $t_c = 60/\text{HR}$, where HR is the heart rate. Notice that $E_H(t)$ is a rescaled version of $E_n(t_n)$ and the constants E_{max} and E_{min} are related to the end-systolic pressure–volume relationship (ESPVR) and the end-diastolic pressure–volume relationship (EDPVR), respectively. Figure 79.4 shows a plot of $E_H(t)$ for a healthy heart with $E_{max} = 2\,\text{mmHg/ml}$, $E_{min} = 0.06\,\text{mmHg/ml}$, and a heart rate of 60 bpm (beats per minute). For a heart with cardiovascular disease, the elastance expression used in our model is modified according to $E(t) = \delta E_H(t)$. That is, the elastance $E_H(t)$ is scaled with a factor $0 < \delta \leq 1$, where $\delta = 1$ represents a healthy heart and smaller values of δ are used to represent cardiovascular disease. The more severe the disease, the smaller the value of δ. Also in the model, preload and pulmonary circulations are represented by the capacitance C_R; the aortic compliance is represented by the capacitance C_A, and afterload is represented by the four-element Windkessel model [79.19] comprising R_C, L_S, C_S, and R_S. Preload, or venous blood returning to the heart, is closely related to the cardiac output (CO) produced by the heart for a given level of contractility. Afterload can be described as the pressure that the left ventricle has to generate in order to eject blood. It refers to the vascular resistance that the heart sees as it pumps blood. The mitral and aortic valves (Fig. 79.1) are represented by two nonideal diodes consisting of a resistance R_M and ideal diode D_M for the mitral valve, and resistance R_A and ideal diode D_A for the aortic valve. In this representation, we have kept the number of model parameters to a minimum while maintaining enough complexity in the model so that it can reproduce the hemodynamics of the left ventricle. Table 79.1 lists the various system parameters and their typical associated values [79.20–22].

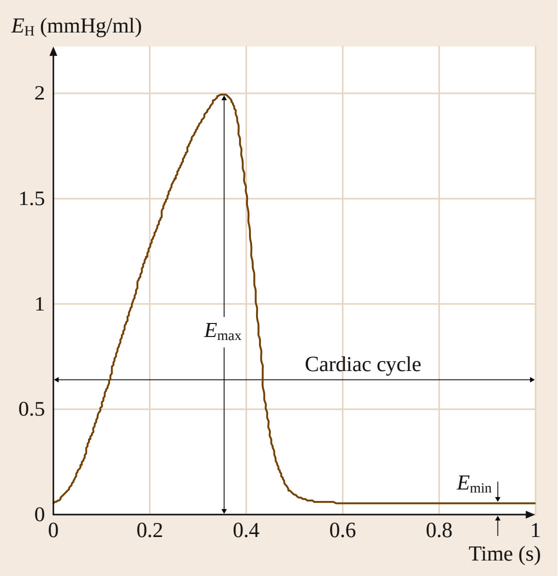

Fig. 79.4 Elastance function $E_H(t) = \frac{1}{C(t)}$ of a healthy heart (cardiac cycle = 60 /HR)

Obviously the circuit model in Fig. 79.3 is time-varying because of the capacitance $C(t)$ and nonlinear because of the two diodes. Since each ideal diode has two states: open-circuit (O/C) and short-circuit (S/C),

Table 79.1 Model parameters

Parameters	Value	Physiological meaning
Resistances (mmHg s/ml)		
R_S	1.0000	Systemic vascular resistance (SVR)
R_M	0.0050	Mitral valve resistance
R_A	0.0010	Aortic valve resistance
R_C	0.0398	Characteristic resistance
Compliances (ml/mmHg)		
$C(t)$	Time-varying	Left ventricular compliance
C_R	4.4000	Left atrial compliance
C_S	1.3300	Systemic compliance
C_A	0.0800	Aortic compliance
Inertances (mmHg s^2/ml)		
L_S	0.0005	Inertance of blood in aorta
Valves		
D_M		Mitral valve
D_A		Aortic valve

Table 79.2 Phases of the cardiac cycle

Modes	Valves		Phases
	Mitral	Aortic	
1	Closed	Closed	Isovolumic relaxation
2	Open	Closed	Filling
1	Closed	Closed	Isovolumic contraction
3	Closed	Open	Ejection
–	Open	Open	Not feasible

Table 79.3 State variables in the cardiovascular model

Variables	Name	Physiological meaning (unit)
$x_1(t)$	LVP(t)	Left ventricular pressure (mmHg)
$x_2(t)$	LAP(t)	Left atrial pressure (mmHg)
$x_3(t)$	AP(t)	Arterial pressure (mmHg)
$x_4(t)$	AoP(t)	Aortic pressure (mmHg)
$x_5(t)$	$Q_\mathrm{T}(t)$	Total flow (ml/s)

four different circuits representing different phases of the ventricular function can therefore be modeled. When D_M is S/C and D_A is O/C (i. e., the mitral valve is open and aortic valve is closed) the circuit in Fig. 79.3 represents the phase when the left ventricle is filling. When D_M is O/C and D_A is S/C (i. e., the mitral valve is closed and the aortic valve is open) the circuit represents the phase when the ventricle is ejecting. The circuit in which both diodes are O/C (i. e., both the mitral and aortic valves are closed) will occur twice and represents the phase when the ventricle is undergoing isovolumic contraction and relaxation. Finally, the circuit in which both diodes are S/C (i. e., both the mitral and aortic valves are open) is clearly not feasible. The three different phases of operation of the left ventricle over four consecutive different time intervals within the cardiac cycle are summarized in Table 79.2. Every phase within the cardiac cycle is therefore modeled by a different equivalent circuit and hence a different set of linear time-varying differential equations. However, by appropriately modeling the diodes as nonlinear elements, it is possible to write only one set of differential equations, which describes the behavior of the entire model for all three phases. Selecting the state variables as the hemodynamic variables listed in Table 79.3 (and shown on the circuit in Fig. 79.2), and using basic circuit analysis methods [79.23] such as Kirchhoff's voltage and current laws (KVL and KCL), we can derive the state equations for the cardiovascular circuit model shown in Fig. 79.2 as

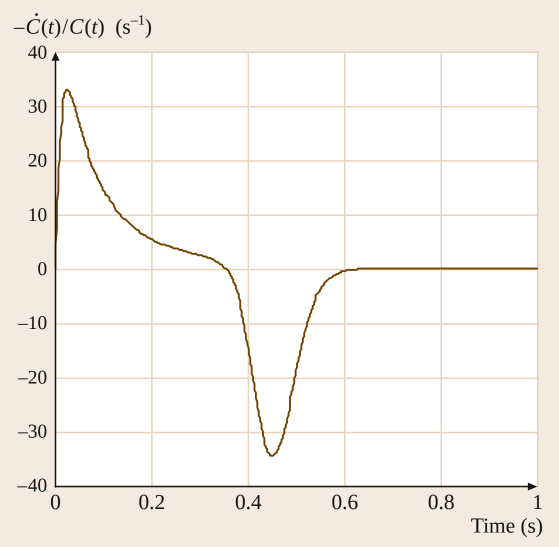

Fig. 79.5 Plot of $\frac{-\dot{C}(t)}{C(t)}$ for a healthy heart over one cardiac cycle

$$

0 & 0
\end{pmatrix}
\begin{pmatrix} \frac{1}{R_\mathrm{M}} r(x_2 - x_1) \\ \frac{1}{R_\mathrm{A}} r(x_1 - x_4) \end{pmatrix} .
\tag{79.4}
$$

In (79.4) $\dot{C}(t) = \mathrm{d}C(t)/\,\mathrm{d}t$ and $r(x)$ represents the ramp function

$$
r(\xi) = \begin{cases} \xi & \text{if} \quad \xi \geq 0\,, \\ 0 & \text{if} \quad \xi < 0\,. \end{cases}
\tag{79.5}
$$

We note that the model described above is an autonomous switched linear time-varying system over four different phases within the cardiac cycle [79.15, 16]. Its solution is oscillatory due to the cyclic nature of the terms $\dot{C}(t)$ and $1/C(t)$ in the matrices in (79.4). A plot of the expression $-\dot{C}(t)/C(t)$ over one cardiac cycle for a healthy heart is shown in Fig. 79.5. The term $1/C(t)$ represents the elastance function $E_\mathrm{H}(t)$ whose plot is shown in Fig. 79.4.

79.2 Cardiovascular Model Validation

The ability of the fifth-order model described in the previous section to emulate the hemodynamics of the left ventricle is demonstrated by simulating the model for both nominal steady-state conditions, and in response to perturbations of preload and afterload. Figure 79.6 shows the simulation waveforms of the hemodynamics for an adult with heart rate of 75 bpm. In this particular case, systolic and diastolic pressure were 117 and 77 mmHg, mean aortic pressure (MAP) was 99 mmHg, cardiac output (CO) (i. e., the blood pumped by the ventricle in 1 min) was 5.21 l/min and stroke volume (SV) (i. e., the volume of blood pumped by the ventricle in one cardiac cycle) was 69.5 ml/beat. These numbers and waveforms are all consistent with hemodynamic data in normal subjects described in [79.24].

A second method to validate the model and verify that it can reproduce the human left ventricle behavior is to vary the preload and afterload conditions, while keeping the left ventricle parameters (E_{max}, E_{min}, and V_0) constant. If the model behaves as expected, we should have an approximately linear relationship between end-systolic pressure and left ventricle volume (known as end-systolic pressure–volume relationship, or ESPVR), in spite of changes in preload and afterload. A total of four preload and four afterload conditions were simulated using $E_{\text{max}} = 2\,\text{mmHg/ml}$, $E_{\text{min}} = 0.05\,\text{mmHg/ml}$, and $V_0 = 10\,\text{ml}$. The resulting pressure and volume of the ventricle are typically plotted in the form of pressure–volume (PV-)loops. The PV-loops in Fig. 79.7a, represent the result of changing afterload conditions by selecting different values of systemic vascular resistance (R_S in Fig. 79.3), while keeping end-diastolic volume (EDV) constant.

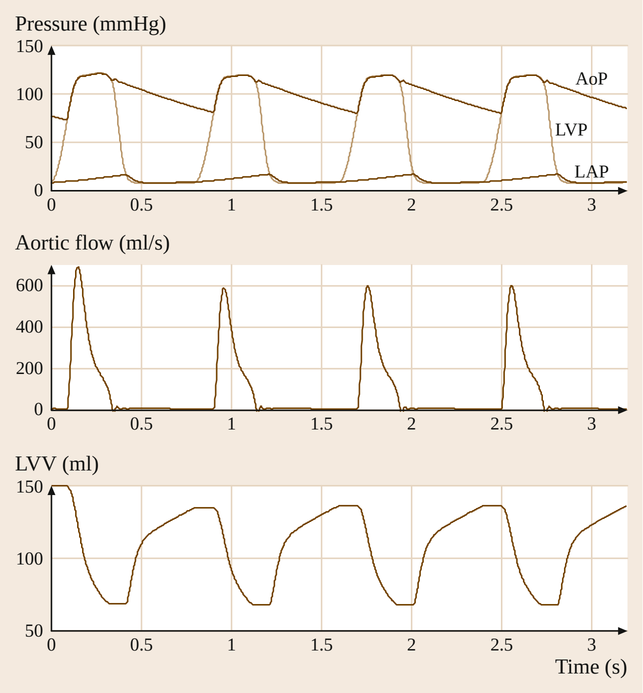

Fig. 79.6 Simulated hemodynamic waveforms for a normal heart

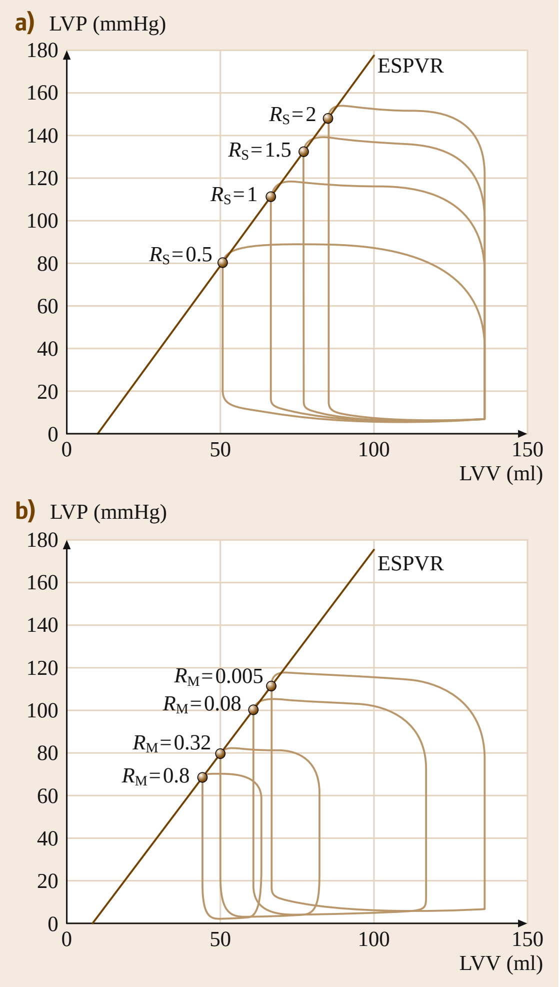

Fig. 79.7a,b PV-loops for different values of (**a**) afterload resistance, and (**b**) preload volume

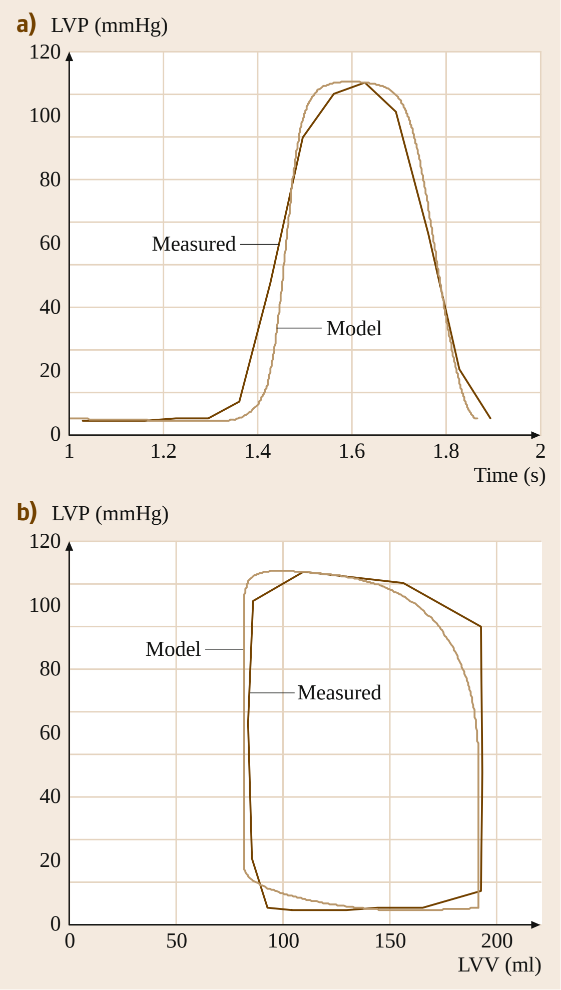
Fig. 79.8a,b Measured and simulated **(a)** left ventricular pressure and **(b)** PV-loops ▶



The PV-loops in Fig. 79.7b represent the result of altering preload conditions by changing the Mitral valve resistance R_M. The linear relationship between pressure and volume is evident in both Fig. 79.7a,b. The slope of the ESPVR and the horizontal intercept for the afterload data in Fig. 79.7a are determined as 1.98 mmHg/ml and 10.91 ml, respectively. For the preload data of Fig. 79.7b these values are determined as 1.92 mmHg/ml and 8.84 ml respectively. These results are consistent with the values used for E_{max} and V_0 used in the simulation and clearly show that the cardiovascular model can indeed mimic the behavior of the left ventricle.

Finally, a third method to validate the model is to compare the hemodynamic waveforms obtained from the model to those of a human patient. Figure 79.8 shows left ventricular pressure data and the corresponding PV-loop obtained from our model using values $E_{max} = 1.5$ mmHg/ml and $V_0 = 12$ ml estimated from real data of a patient suffering from cardiomyopathy. The measured data from the patient are also superimposed on the same plots in Fig. 79.8. Clearly the data from the model exhibit a close fit to the real measured patient data. As a test for how close the two data sets match, in the case of LVP, the error was calculated to be 4.4% and in the case of the PV-loop, the area within the loop, known as the stroke work (SW), was determined to be 10 492 mmHg · ml for the PV-loop of the model and 10 690 mmHg · ml for the patient PV-loop, which represents a difference of only 1.85%.

79.3 LVAD Pump Model

The LVAD considered in this chapter is a rotary blood pump connected using two cannulae as a bridge between the left ventricle and the aorta as illustrated in the schematic in Fig. 79.9. The pump (HeartMate II) and its cannulae are characterized by the relationships [79.25]

$$H_p = R_p Q + L_p \frac{dQ}{dt} + \beta\omega^2 , \tag{79.6}$$

$$H_i = R_i Q + L_i \frac{dQ}{dt} , \tag{79.7}$$

$$H_o = R_o Q + L_o \frac{dQ}{dt} , \tag{79.8}$$

where H_p, H_i, and H_o are the pressure differences across the pump and the inlet and outlet cannulae, respectively, Q is the flow rate of blood through the pump and cannulae, and ω is the pump rotational speed. The parameters R_p, R_i, and R_o represent the resistances and the parameters L_p, L_i, and L_o represent the inertances of the pump and cannulae, respectively. The parameter β is a pump-dependent constant. We note that R_i repre-

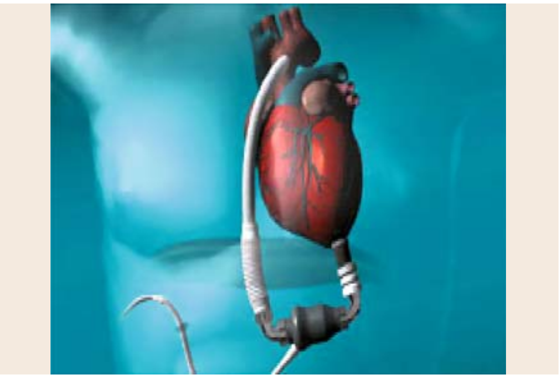


Fig. 79.9 Schematic of a rotary LVAD connected between the left ventricle and the aorta

Table 79.4 Model parameters for the LVAD

Parameters	Value	Physiological meaning
Cannulae resistances (mmHg s/ml)		
R_{su}	See (79.9)	Suction resistance with parameters $\alpha = -3.5\,\text{s/ml}$ and $\bar{x}_1 = 1\,\text{mmHg}$
R_i	0.0677	Inlet cannula resistance
R_p	0.17070	Outlet cannula resistance
R_o	0.0677	Pump resistance
Cannulae inertances (mmHg s^2/ml)		
L_i	0.0127	Inlet cannula inertance
L_p	0.02177	Pump inertance
L_o	0.0127	Outlet cannula inertance
Pump parameter (mmHg/(rpm)^2)		
β	9.9025×10^{-7}	

sents the resistance of the inlet cannula when no suction is present. When suction occurs, an additional resistance R_{su} in the form [79.5, 26]

$$R_{su} = \begin{cases} 0 & \text{if} \quad \text{LVP}(t) > \bar{x}_1 \\ \alpha(\text{LVP}(t) - \bar{x}_1) & \text{if} \quad \text{LVP}(t) \le \bar{x}_1 \end{cases} \tag{79.9}$$

is added to the expression in (79.7) to represent this phenomenon. Clearly, R_{su} is a nonlinear time-varying resistance whose value is zero when the pump is operating normally and is activated when the left ventricular pressure LVP(t) (or $x_1(t)$) becomes less than a predetermined small threshold $\bar{x}_1$, a condition that represents suction. The value of R_{su} when suction occurs increases linearly as a function of the difference between LVP(t) and the threshold $\bar{x}_1$. The parameter α is a cannula-dependent scaling factor. An equivalent circuit model for the LVAD and inlet and outlet cannulae is shown in Fig. 79.10. Values of all parameters mentioned above for the specific LVAD used in our model are given in Table 79.4. The state equation governing the behavior of the LVAD can now be easily derived as

$$\text{LVP}(t) - \text{AoP}(t) = R^* Q + L^* \frac{dQ}{dt} + \beta\omega^2 \,, \tag{79.10}$$

where

$$R^* = R_{su} + R_i + R_p + R_o \tag{79.11}$$

and

$$L^* = L_i + L_p + L_o \,. \tag{79.12}$$

79.4 Combined Cardiovascular and LVAD Model

Figure 79.11 shows the equivalent electric circuit of the combined cardiovascular and LVAD model. The addition of the LVAD to the model represented in (79.4) adds one state variable $x_6(t) = Q$, which represents the blood flow through the pump and eight passive parameters R_{su}, R_i, R_p, R_o, L_i, L_p, L_o, and β. Note that the combined cardiovascular and LVAD model is now a forced system, where the primary control variable is the pump speed ω. As was done for the cardiovascular model, the state equations for this combined sixth-order model can be derived from basic circuit analysis techniques and written in the form

$$
\begin{pmatrix}\frac{\mathrm{d}x_1(t)}{\mathrm{d}t}\\ \frac{\mathrm{d}x_2(t)}{\mathrm{d}t}\\ \frac{\mathrm{d}x_3(t)}{\mathrm{d}t}\\ \frac{\mathrm{d}x_4(t)}{\mathrm{d}t}\\ \frac{\mathrm{d}x_5(t)}{\mathrm{d}t}\\ \frac{\mathrm{d}x_6(t)}{\mathrm{d}t}\end{pmatrix}
=
\begin{pmatrix}
\frac{-\dot{C}(t)}{C(t)} & 0 & 0 & 0 & 0 & \frac{-1}{C(t)}\\
0 & \frac{-1}{R_\mathrm{S}C_\mathrm{R}} & \frac{1}{R_\mathrm{S}C_\mathrm{R}} & 0 & 0 & 0\\
0 & \frac{1}{R_\mathrm{S}C_\mathrm{S}} & \frac{-1}{R_\mathrm{S}C_\mathrm{S}} & 0 & \frac{1}{C_\mathrm{S}} & 0\\
0 & 0 & 0 & 0 & \frac{-1}{C_\mathrm{A}} & \frac{1}{C_\mathrm{A}}\\
0 & 0 & \frac{-1}{L_\mathrm{S}} & \frac{1}{L_\mathrm{S}} & \frac{-R_\mathrm{C}}{C_\mathrm{S}} & 0\\
\frac{1}{L^*} & 0 & 0 & \frac{-1}{L^*} & 0 & \frac{-R^*}{L^*}
\end{pmatrix}
\times
\begin{pmatrix}x_1(t)\\ x_2(t)\\ x_3(t)\\ x_4(t)\\ x_5(t)\\ x_6(t)\end{pmatrix}
+
\begin{pmatrix}
\frac{1}{C(t)} & \frac{-1}{C(t)}\\
\frac{-1}{C_\mathrm{R}} & 0\\
0 & 0\\
0 & \frac{1}{C_\mathrm{A}}\\
0 & 0\\
0 & 0
\end{pmatrix}
\times
\begin{pmatrix}\frac{1}{R_\mathrm{M}}r(x_2-x_1)\\ \frac{1}{R_\mathrm{A}}r(x_1-x_4)\end{pmatrix}
+
\begin{pmatrix}0\\0\\0\\0\\0\\ \frac{\beta}{L^*}\end{pmatrix}
u(t)\,. \tag{79.13}
$$

The control variable in (79.13) is $u(t) = \omega^2(t)$, where $\omega(t)$ is the rotational speed of the pump. Using control terminology, and after some simple algebraic manipulations, this model can be expressed as a switched time-varying linear system in the standard state-space form [79.15, 16]

$$
\frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}t} = \mathbf{A}_k(t)\boldsymbol{x} + \boldsymbol{b}u\,, \qquad k = \mathrm{I}\,, \mathrm{F}\,, \mathrm{E}\,, \tag{79.14}
$$

where $\boldsymbol{x} = [x_1\,, x_2\,, x_3\,, x_4\,, x_5\,, x_6]^\top$ is the state vector, $\boldsymbol{b} = (0, 0, 0, 0, 0, \beta/L^*)^\top$, and $(\ )^\top$ denotes transpose. The matrix $\mathbf{A}_k(t)$ in (79.14) switches over each of the four different phases within the cardiac cycle (Table 79.2). The description of this matrix over each of these regions is given as follows.

1. *Isovolumic relaxation and contraction phases* ($k = \mathrm{I}$): Within these two intervals we have $x_2 - x_1 < 0$ and $x_1 - x_4 < 0$. The matrix $\mathbf{A}_k(t)$ will take the form

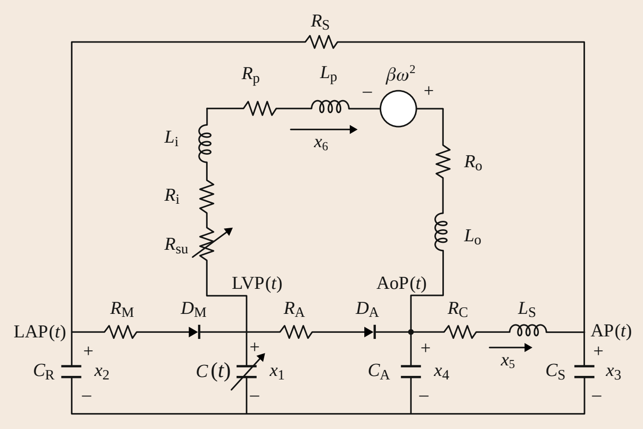

Fig. 79.11 Combined cardiovascular and LVAD model

$$
\mathbf{A}_\mathrm{I}(t) =
\begin{pmatrix}
\frac{-\dot{C}(t)}{C(t)} & 0 & 0 & 0 & 0 & \frac{-1}{C(t)}\\
0 & \frac{-1}{R_\mathrm{S}C_\mathrm{R}} & \frac{1}{R_\mathrm{S}C_\mathrm{R}} & 0 & 0 & 0\\
0 & \frac{1}{R_\mathrm{S}C_\mathrm{S}} & \frac{-1}{R_\mathrm{S}C_\mathrm{S}} & 0 & \frac{1}{C_\mathrm{S}} & 0\\
0 & 0 & 0 & 0 & \frac{-1}{C_\mathrm{A}} & \frac{1}{C_\mathrm{A}}\\
0 & 0 & \frac{-1}{L_\mathrm{S}} & \frac{1}{L_\mathrm{S}} & \frac{-R_\mathrm{C}}{L_\mathrm{S}} & 0\\
\frac{1}{L^*} & 0 & 0 & \frac{-1}{L^*} & 0 & \frac{-R^*}{L^*}
\end{pmatrix}
. \tag{79.15}
$$

2. *Filling phase* ($k = \mathrm{F}$): Within this interval we have $x_2 - x_1 \geq 0$ and $x_1 - x_4 < 0$. The matrix $\mathbf{A}_k(t)$ will take the form

$$
\mathbf{A}_\mathrm{F}(t) =
\begin{pmatrix}
\frac{-\dot{C}(t)}{C(t)} - \frac{1}{R_\mathrm{M}C(t)} & \frac{1}{R_\mathrm{M}C(t)} & 0 & 0 & 0 & \frac{-1}{C(t)}\\
\frac{1}{R_\mathrm{M}C_\mathrm{R}} & \frac{-1}{C_\mathrm{R}}\left(\frac{1}{R_\mathrm{M}} + \frac{1}{R_\mathrm{S}}\right) & \frac{1}{R_\mathrm{S}C_\mathrm{R}} & 0 & 0 & 0\\
0 & \frac{1}{R_\mathrm{S}C_\mathrm{S}} & \frac{-1}{R_\mathrm{S}C_\mathrm{S}} & 0 & \frac{1}{C_\mathrm{S}} & 0\\
0 & 0 & 0 & 0 & \frac{-1}{C_\mathrm{A}} & \frac{1}{C_\mathrm{A}}\\
0 & 0 & \frac{-1}{L_\mathrm{S}} & \frac{1}{L_\mathrm{S}} & \frac{-R_\mathrm{C}}{L_\mathrm{S}} & 0\\
\frac{1}{L^*} & 0 & 0 & \frac{-1}{L^*} & 0 & \frac{-R^*}{L^*}
\end{pmatrix}
. \tag{79.16}
$$

3. *Ejection phase* ($k = \mathrm{E}$): Within this interval we have $x_2 - x_1 < 0$ and $x_1 - x_4 \geq 0$. The matrix $\mathbf{A}_k(t)$ will

take the form

$$\mathbf{A}_{\mathrm{E}}(t) = \begin{pmatrix} \frac{-\dot{C}(t)}{C(t)} - \frac{1}{R_{\mathrm{A}}C(t)} & 0 & 0 & \frac{1}{R_{\mathrm{A}}C(t)} & 0 & \frac{-1}{C(t)} \\ 0 & \frac{-1}{R_{\mathrm{S}}C_{\mathrm{R}}} & \frac{1}{R_{\mathrm{S}}C_{\mathrm{R}}} & 0 & 0 & 0 \\ 0 & \frac{1}{R_{\mathrm{S}}C_{\mathrm{S}}} & \frac{-1}{R_{\mathrm{S}}C_{\mathrm{S}}} & 0 & \frac{1}{C_{\mathrm{S}}} & 0 \\ \frac{1}{R_{\mathrm{A}}C_{\mathrm{A}}} & 0 & 0 & \frac{-1}{R_{\mathrm{A}}C_{\mathrm{A}}} & \frac{-1}{C_{\mathrm{A}}} & \frac{1}{C_{\mathrm{A}}} \\ 0 & 0 & \frac{-1}{L_{\mathrm{S}}} & \frac{1}{L_{\mathrm{S}}} & \frac{-R_{\mathrm{C}}}{L_{\mathrm{S}}} & 0 \\ \frac{1}{L^*} & 0 & 0 & \frac{-1}{L^*} & 0 & \frac{-R^*}{L^*} \end{pmatrix} . \tag{79.17}$$

Switched linear systems have been studied extensively in recent years, especially with regards to stability and stabilization [79.27, 28]. The development of an optimal feedback controller for the above system will present a major control challenge, especially in guaranteeing that the resulting closed-loop autonomous system will also be stable.

79.5 Challenges in the Development of a Feedback Controller and Suction Detection Algorithm

In assisting the heart, the amount of blood flow required of an LVAD depends on the patient's level of activity, emotional state, posture, and other physiological demands. The response of the heart itself due to changes in demand is governed by its contractility, and the preload and afterload. Contractility of the heart is related to the intrinsic ability of the heart muscle to contract. As mentioned earlier, preload is closely related to the cardiac output (CO) produced by the heart for a given level of contractility and afterload can be described as the pressure that the left ventricle has to generate in order to eject blood. Everything else held equal, if afterload increases, cardiac output will decrease. In a healthy heart, these internal control mechanisms provide the cardiovascular system with a significant capability to respond to changes in demand for blood flow in the body.

When a rotary LVAD is implanted in a patient with congestive heart failure, the only available mechanism to control it is the rotational speed ω of the pump. Currently, patients with rotary LVADs are typically kept in a critical care setting and are continuously supervised by human operators. When the patient is in a stable condition, the operator adjusts the pump speed manually so as to achieve the desired levels of the hemodynamic variables and ensure the well being of the patient. However, for a patient whose level of activity is continuously changing, this manual open-loop control becomes impractical. Its limitations will become even more apparent as patients are rehabilitated and seek to adopt a normal active lifestyle. The inability of open-loop manual control to respond automatically to changes in demand can dramatically impact the quality of life of LVAD patients [79.3, 4]. For successful long-term implantation of these devices, the need for a human to monitor the device operation must therefore be eliminated. In order to achieve a desired level of automatic operation, a feedback controller which is capable of continuously monitoring the patient's status to recognize a change in the level of activity and automatically adjust the pump speed must be incorporated in the device. As mentioned earlier, such a controller must also meet the other objective of ensuring that suction does not occur by unnecessary excessive pumping. The achievement of these two objectives has been a major

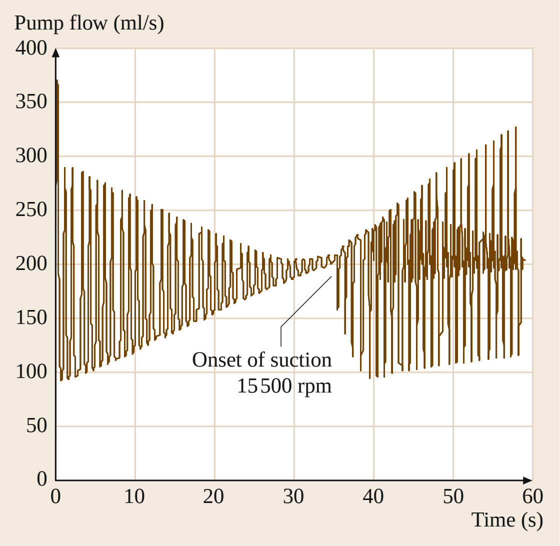

Fig. 79.12 Pump flow signal from human cardiovascular/LVAD model as a function of linearly increasing pump speed

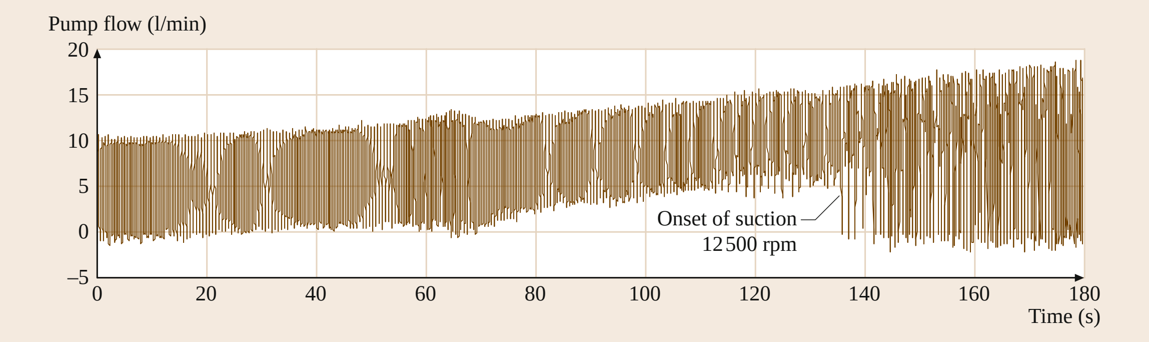

Fig. 79.13 Pump flow signal from in vivo data as a function of linearly increasing pump speed

challenge for LVAD developers for over 15 years and is recognized as one of the most serious limitations of this technology at the present time.

The design of a stable feedback controller based on the model developed earlier in this chapter is very much related to our ability to continuously measure, or estimate, in real time the patient's hemodynamic variables (x_1 through x_5 in the model). The patient's continuously varying levels of physical and emotional activities are exhibited by possibly wide variations in the systemic vascular resistance (R_s in the model), which in turn affects all six state variables in the system. Unfortunately, at present, current technology for implantable sensors that allow for continuous measurements of the patient's hemodynamic variables does not exist and will probably need many years before it can be developed. The pump flow variable x_6, on the other hand, appears to be the only variable that can be measured in real time. This may be done, for example, by using standard ultrasonic flow transducers that can be clamped onto one of the pump cannulae. With this single variable, the problem essentially reduces to a feedback controller design based on incomplete state measurements. Given that the system is nonlinear and time varying, this remains a challenge from both the theoretical and practical considerations. An attempt to develop a very simple feedback controller based on the slope of the lower envelope of the pump flow signal has recently been made [79.29] but its practical usefulness in an in vivo experiment has not yet been tested. The approach of estimating the hemodynamic variables (x_1 through x_5) so as to implement a full state feedback controller has also been considered but with limited success [79.30–34]. This is largely due to the fact that this approach involves first estimating the patient's systemic vascular parameters. Most methods developed for estimating these parameters suffer from the problem that the estimates obtained are discrete and valid only over parts of the cardiac cycle. A method for simultaneously estimating the parameters and the hemodynamic variables has been developed in [79.21, 22] based on an extended Kalman filter approach; however, the robustness of the method with respect to parameter initialization remains questionable and its usefulness is limited due to uncertainties related to convergence of the algorithm to the correct estimates. In summary, the design of a feedback controller for the LVAD remains a very challenging open problem.

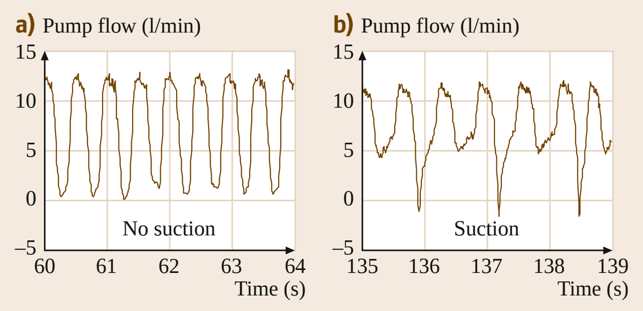

Fig. 79.14a,b In vivo pump flow signal **(a)** when pump is operating normally, and **(b)** when pump is in suction

Since the pump flow signal appears to be the only signal that is directly measurable, it is important to examine how this signal is affected by the pump speed as it changes over its allowable safe range. Figure 79.12 shows a plot of this signal (state variable x_6) when our model is exited with a pump speed starting at 12 000 rpm and increasing linearly according to $\omega = 12\,000 + 100t$, reaching a speed of 18 000 rpm after 60 s. It is clear from this figure that the lower envelope of this signal seems to track the increasing pump speed up to a point when a breakdown occurs and then exhibits a sudden drop when the speed is increased beyond the breakpoint. In Fig. 79.12, this breakdown occurs at $t = 35$ s, which corresponds to a speed of about 15 500 rpm and is indicative of the onset of suction in the model. The same phenomenon has been observed in an in vivo animal study (authorized according to WorldHeart, Inc. IRB DO 01-06002) in which the WorldHeart (World Heart Inc.: Formerly MedQuest, Inc., Salt Lake City, UT) rotary LVAD was used. In this study the pump speed was increased linearly from 8000 rpm according to $\omega = 8000 + \frac{100}{3}t$ and reached a speed of 14 000 rpm after 180 s. The corresponding measured pump flow signal is shown in Fig. 79.13. Again, in this case, a similar breakdown in the lower envelope of the signal is observed at $t = 136$ s, which corresponds to a speed 12 500 rpm, indicating the onset of suction in the animal's left ventricle. It is interesting to note that, in both the model simulation and the in vivo experiment, the onset of suction appears to be characterized by a sudden large drop in the lower envelope of the pump flow signal. Furthermore, when the pump is in suction for some time, a noticeable change in the characteristics of the signature of the pump flow signal is observed. This is clearly seen in Fig. 79.14 in which the details of the in vivo data of Fig. 79.13 are shown over two 5 s intervals of time from 60 to 64 s before the occurrence of suction and from 135 to 139 s during suction. The change in the frequency characteristics of the signal from a narrow-band signal to a relatively broad-band signal is very noticeable. The breakpoint in the lower envelope of the pump flow signal and the changes in its frequency characteristics before and after suction represent opportunities that can be exploited in the development of suction detection algorithms. We should note that suction detection has been a long-standing problem that has been studied ever since the rotary LVAD was introduced. Many algorithms have been proposed based on numerous other criteria and indices [79.35–39]. A successful attempt to develop a suction detection algorithm based on the frequency characteristics of the pump flow signal has recently been reported [79.40, 41].

79.6 Conclusion

In this chapter, a sixth-order state-space model of a left ventricular assist device connected to a cardiovascular system is presented. The model is obtained by combining a fifth-order model of the hemodynamics of the cardiovascular system with a first-order model of the blood flow in a rotary pump along with its inlet and outlet cannulae. The phenomenon of suction is accounted for by including a nonlinear resistance in the model of the inlet cannula. The resulting combined model is nonlinear and time-varying with a different mathematical description over the four different time intervals which correspond to the four phases of the ventricular functions within one cardiac cycle. The only control variable in the model is the rotational speed of the pump. Given that current implantable sensor technology does not exist for measuring the patient's hemodynamic variables, the challenges in using this model to design a feedback speed controller for the LVAD are discussed. The characteristics of the pump flow signal – which is the only directly measurable variable – when the pump is operating normally with no suction and when it is operating in suction are also described based on data obtained from the model as well as from an in vivo animal experiment. Possible approaches for exploiting these characteristics in the development of suction detection algorithms are also discussed.

80. Medical Informatics

Chin-Yin Huang

All of today's patients receive healthcare services from a team of healthcare practitioners through various integrated medical information systems and automated systems. Due to the requirements of accuracy, safety, privacy, and responsiveness on healthcare services, medical informatics itself has become an important research field. This chapter intends to introduce medical informatics from the perspectives of (1) integration, (2) database and data warehouse, (3) individual medical support systems, and (4) medical knowledge and decision support systems. For integration, standard protocols (e.g., HL7, EDIFACT, and DICOM) are important connectivity agreements for hospital information system (HIS), medical support systems and healthcare equipment. For database and data warehouse, this chapter introduces the important concept of link relationships between data tables. The value of medical database and data warehouse relies on the correct link relationships. All modern healthcare organizations consist of multiple separated yet integrated systems. For individual medical support systems, this chapter introduces imaging, laboratory, hospital pharmacy, and nursing information systems. Evidence-based medicine and data mining techniques are two important fields in today's medical knowledge and decision support systems. Finally, this chapter introduces how to strategically introduce healthcare information systems into a healthcare organization. Emerging issues of care quality, security, and public-use databases are also introduced.

80.1 Background

Traditional medical informatics is defined as a scientific field that studies information collection, processing, and communication related to healthcare services. As information and communication technologies are advancing rapidly, the domain of medical informatics is expanding. Traditional medical informatics that focuses on data transactions is no longer enough in modern hospitals. Technologies of biomedical data mining, medical decision support, medical image processing, telemedicine, etc., are filling in and expanding the domain of medical informatics. Furthermore, healthcare behaviors have changed and improved accordingly due to those technologies.

The objective of this chapter is to summarize the technologies that are being applied in today's healthcare organizations. Some emerging and advanced issues are also addressed. The remainder of this chapter is organized as follows. First, a diagnostic–therapeutic cycle is presented to demonstrate a common healthcare behavior. Then, basic needs and standards that are required for communication and integration in a hospital are introduced. Besides communication, database and data warehouse are another two key elements of medical informatics. This chapter also gives an example of data warehouse schema. Then, four basic functions of medical support systems are illustrated: imaging information systems, laboratory information systems, hospital pharmacy information systems, and nursing information systems. Issues of medical knowledge and decision support system are presented by pointing out two topics: evidence-based medicine and data mining techniques. This chapter suggests that people, project management, and strategic planning are the three crucial elements that decide whether a healthcare information system can be successfully developed. Finally, emerging issues related to medical informatics such as quality of care, security, and public-use databases are presented.

Although this chapter summarizes modern healthcare technologies that are applied in the healthcare services, *integration* is an important technical issue. For healthcare organizations, communication technologies (e.g., internet, local area network, WiFi, TCP/IP, etc.) provide the infrastructure for connectivity. However, to make all the healthcare practitioners and modern medical care systems work together efficiently and accurately for all kinds of service activities integration in a higher level must be relied upon. Such an integration and coordination challenge was pointed out by *Sarter* et al. [80.1] in 1997. Today, the integration is fulfilled by all kinds of medical standard protocols (e.g., Health Level 7 (HL7) and digital imaging and communication in medicine (DICOM)). These issues of integration are addressed in this chapter.

80.2 Diagnostic–Therapeutic Cycle

In healthcare, medical doctors make medical therapeutic decisions based on a diagnostic–therapeutic cycle [80.2]. There are three stages in the cycle: observation, diagnosis, and therapy. Observation is the most fundamental step in therapy. It can be done by the healthcare practitioner with simple assistant tools, such as stethoscopes. Observations may also be done through relatively simple blood tests or x-ray systems, or through a complicated facility, such as computed tomography (CT) or an intestinal endoscope. Beside the above-mentioned observations that are done one to several times, observations can last for a certain time period by using equipment, such as the Holter electrocardiograph.

Fig. 80.1 Two computer screens for medical diagnosis (photo courtesy of Cheng Ching General Hospital)

Medical doctors perform diagnosis based on the results of observations and patient history (anamnesis). Its goal is to identify the causes of (1) patients' complaints

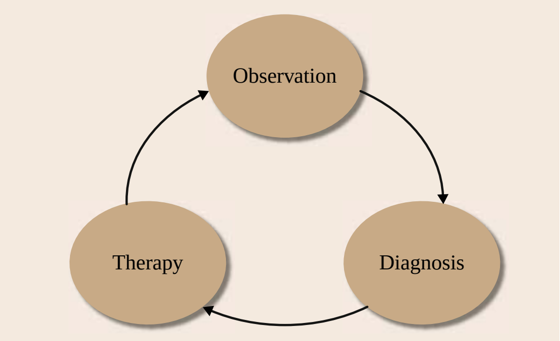

Fig. 80.2 Diagnostic–therapeutic cycle

and (2) results of observations. Figure 80.1 shows two computer screens for a medical doctor when checking patients. The left screen is used to display the results of observation (x-ray), whereas the right screen is an order entry system to show anamnesis and other results of tests. Diagnosis may take a long time, since the patients may describe their complaints incompletely, which may lead the doctor to order the wrong tests or treatments. Then, an iterative observation-diagnosis-therapy occurs. For patients who have chronic diseases, iterations may repeat over and over for a long time period. However, sometimes the iterations occur because of mistakes/errors resulting from doctors, pharmacists, nurses, or inspecting staffs and/or facilities.

Therapy cannot be done without the orders from doctors. It may be done through medication, surgery, rehabilitation, or diet control. Technologies of therapy are constantly evolving. Due to its advancement, life quality of patients is improving.

Observation, diagnosis, and therapy form a cycle (Fig. 80.2). The cycle stops only when the patient is cured or decides to quit the cycle.

80.3 Communication and Integration

Medical services in modern hospitals are fulfilled by a group of specialists: physicians, nurses, pharmacists, biologists, and administrative and laboratory staffs. Moreover, medical services are fulfilled by advanced facilities, and information and computer technologies. Patients are cared for by an integrated system consisting of the above-mentioned specialists and expensive facilities. The integrated system can function efficiently and effectively only when the individual persons or facilities can be integrated through a communication system.

Communication as a key component for integration requires two elements: channels and interfaces. Channels mean how the persons or facilities are connected. Most medical facilities can offer communication with a local area network (LAN) by applying TCP/IP standard protocol. Therefore, specialists can upload/download or operate the facilities within the LAN. Associated clinics or outside laboratories may be authorized to use the Internet as a channel to obtain data from the facilities of hospitals. For short distance transmissions, WiFi provides a wireless alternative of communication. It is useful for a doctor to display patient records or to give a medical order when checking with a patient in a ward with a mobile/wireless handheld device, personal digital assistance (PDA) for example. Figure 80.3 shows a portable computerized order entry device. It is a WiFi and web ready system. By its powerful computing, communication, and graphic capabilities, physicians can display the test results of patients and give treatment or medication orders when they are checking with patients anywhere in the WiFi coverage zone.

Interface means that facilities speak the same language. Usually an interface is fulfilled by standards. For administrative data exchange in healthcare, Electronic Data Interchange for Administration, Commerce and Transport (EDIFACT) is used in Europe [80.3], whereas Health Level 7 (HL7) is used in the United States [80.4]. With the standards, participants (such as clinics, laboratories, drug stores, and insurance companies) can encode and decode messages by the same format, which speeds up communication and enables integration of processes occurring between units of a hospital or between hospitals. For medical images such as x-ray, CT, and magnetic resonance imaging (MRI), digital imaging and communication in medicine (DICOM) is a standard for image communication [80.5]. DICOM also plays a role of standardizing the image inputs/outputs of medical facilities developed by various vendors.

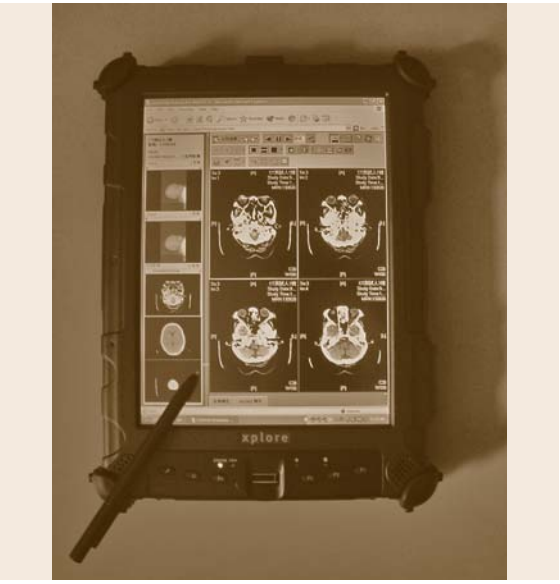

Fig. 80.3 Portable medical order-entry device (photo courtesy of DVNET Technology Co., www.dvnet.biz)

80.4 Database and Data Warehouse

Most healthcare organizations host large databases to maintain the demographical records, complaints and diagnostic records, laboratory tests and inspections, orders of therapy, and insurance and payment records that are associated with each patient. The massive amount of healthcare information requires a database that has a storage capacity of multiple terabytes (TB). There are several reasons why a large storage capacity is required. First, voice, image, and video types of test and inspection data are gradually playing an important role in healthcare. They usually take up large data storage space. Besides, health authorities of government and insurance companies usually demand hospitals to maintain the records for a certain period, which also results in the need for large storage space. Although the cost per byte of data storage is decreasing yearly, larger and more urgent demands on storage space still increase the total cost of database system year by year in modern healthcare organizations.

Though today's object-oriented database (OODB) seems to be a suitable solution to accommodate various data formats, which include text, audio, video, animation, and image, and can manage linked relationships easily, its low performance in transactions hinders the applications of OODB in healthcare organizations. Relational database (RDB) presenting database in flat tables is a typical database for healthcare organizations. The advantages of RDB include supporting the standard structural query language (SQL), scalable performance, and easy maintenance. Besides, because of the abundance of human resource supply in the field of RDB development, operation, and maintenance, RDB is commonly used in healthcare database applications.

However, maintaining large and complicated medical databases may become a financial burden for healthcare organizations, unless the value of medical databases is created. To utilize the value of a large medical database relies on the development of a data warehouse. Data warehouse is a collection of associated databases. Databases in a data warehouse are subject-oriented and nonvolatile. *Subject-oriented* means that the database storage focuses on a special issue, such as patient treatments or medical records for certain cancers. *Nonvolatile* means that the data in a data warehouse should be extracted from the databases and are not changed by online transactions. Besides, the online analytical process (OLAP) is an important function to retrieve useful information from a data warehouse. Basic command functions of OLAP include rolling up, drilling down, slicing, dicing, etc. [80.6]. However, to successfully apply OLAP depends on how well the data warehouse is defined.

A data warehouse is defined by specifying the link relationships among flat tables. Figure 80.4 shows an example to demonstrate link relationships among tables in a data warehouse with fact constellation. It shows that there are many keys for patient order tables. Each

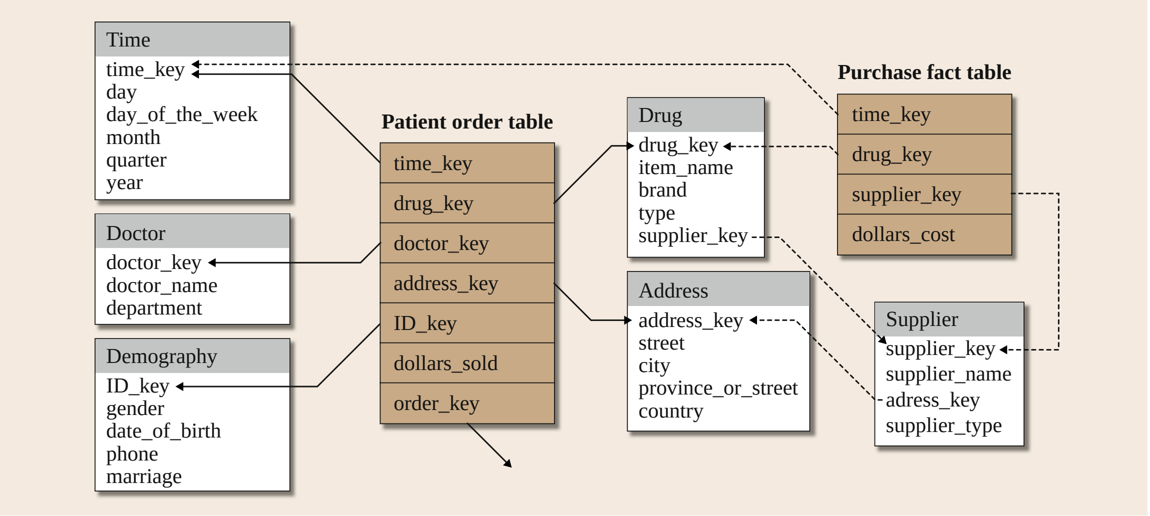

Fig. 80.4 A fact constellation scheme of a data warehouse for patient records

key is linked to other tables. By the links, a user can give an OLAP command. For example, showing the total patient orders for the last month (dicing through time_key), then showing the patients according to the departments they went to visit (drilling down). The drilling down command is possible because the doctor_key links both the patient order table and the doctor table. Through the link, each patient order can find the doctor_key. By querying in the doctor table with the doctor_key, the department is found.

80.5 Medical Support Systems

Today's healthcare activities are supported by information systems and digitized facilities. For this reason, care of patients has become more efficient, timely, and accurate. Medical support systems, besides the hospital information system (HIS) that manages both information of patient care and administration, includes at least four subsystems:

1. Solitary imaging information system
2. Laboratory information system
3. Functions of hospital pharmacy
4. Nursing information systems.

In the following sections, the four subsystems are introduced.

80.5.1 Solitary Imaging Information Systems

Most modern hospitals own expensive solitary imaging systems, such as x-ray, CT, MRI, digital subtraction angiography (DSA), gamma cameras, and positron emission tomography (PET). CT, MRI, and DSA are mostly found in the radiology department, whereas gamma cameras and PETs are found in the nuclear medicine department, since with these radioactive material, which is under government management, is injected into the veins of a patient in the inspection process. Figure 80.5 shows a multislice CT volume scan system. CT is a typical noninvasive examination in today's healthcare services. An examination on a CT involves various kinds of monitor and control of the CT system. Figure 80.6 shows multiple monitoring and control functions on both patients and the CT system. To integrate the solitary imaging systems with HIS requires a standard for exchanging image data. As mentioned in Sect. 80.3, DICOM is a standard for image data exchange. With it, associated healthcare practitioners can view the images across different systems, whether they be inside or outside the hospital. An example of a CT image is shown in Fig. 80.7. Some radiologists even check images of patients in various hospitals through the Internet.

80.5.2 Laboratory Information Systems

Besides solitary imaging systems, many tests may be performed in a laboratory or even a clinical room by portable devices. Equipment in a laboratory may

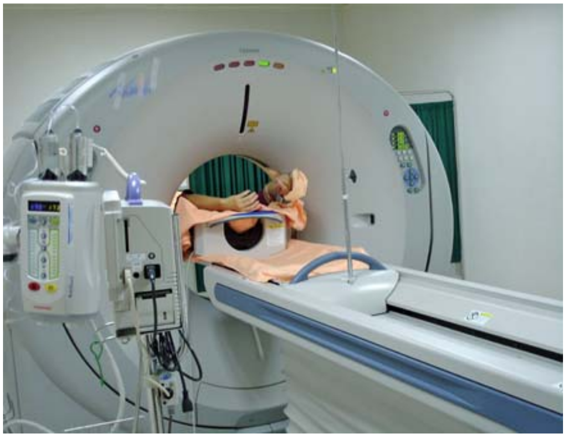

Fig. 80.5 A multislice CT volume scan system (photo courtesy of Cheng Ching General Hospital)

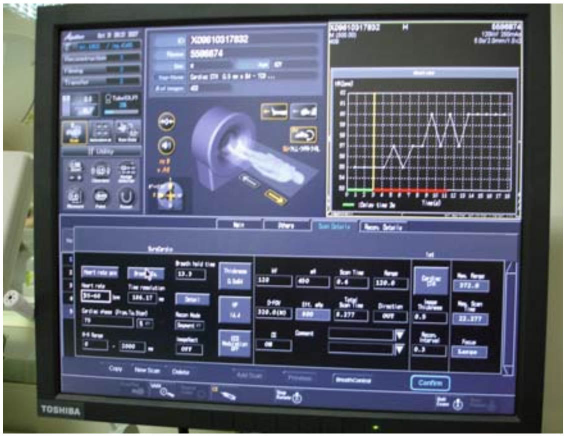

Fig. 80.6 Multiple monitoring and control functions on both patients and CT system

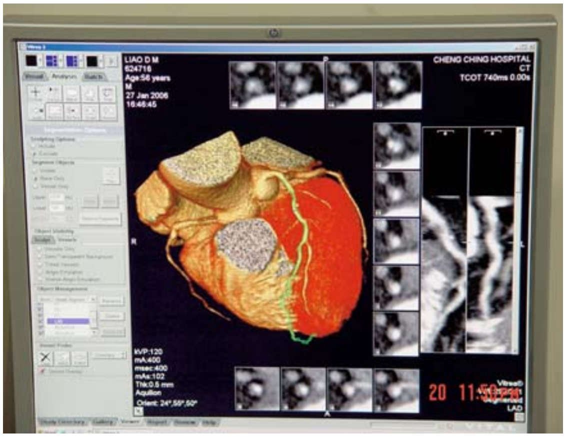

Fig. 80.7 Example of a CT image (photo courtesy of Cheng Ching General Hospital)

include an electrocardiogram (ECG), ultrasound, or spirography. Biosignals produced by the equipment are digitalized and conformed to DICOM, so that they can be integrated into a HIS. Additionally, those biosignals are collected synchronously with patients, which means that the patients must stand by when the biosignals are recording.

Besides the previous synchronous examination, some examinations are asynchronous. In other words, the examinations only need specimens from patients and do not need patients to wait while the equipment is examining. Hospitals host laboratories to give asynchronous examinations of specimens from patients, such as blood and urine. Electron microscopes and centrifuges are typical examples of equipment for laboratories. To perform pathological examinations, the systematized nomenclature of medicine (SNOMED) is a code system that indicates various aspects of a disease [80.7]. It is a checkbook for diseases based on specimens from patients.

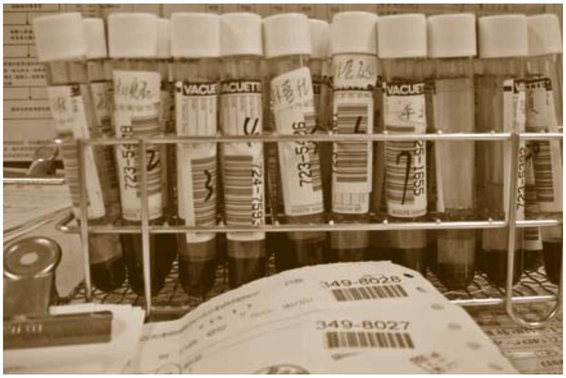

Fig. 80.8 Examples of specimens (each with a barcode)

There are two basic activities that a hospital laboratory has to do for either synchronous or asynchronous examinations. The first activity is about getting samples or biosignals from patients. In the first activity, there must be a system for registering the patient ID and the examinations that were ordered by a doctor. For an asynchronous examination, usually a specimen from a patient is labeled by a barcode that shows the identical patient ID to avoid mismatching with other patients' specimens (Fig. 80.8). As long as the specimens' barcodes are recorded into HIS, laboratory staff schedule a time for the examination. The second activity is to deliver the examination report to HIS. For both synchronous and asynchronous examinations, the examination reports are presented in text, audio, or video and have to be stored in the database of HIS so further diagnoses or therapies can be ordered by a doctor.

Usually a laboratory information system involves various kinds of workflows. Those workflows instruct the administrative and laboratory staffs to efficiently deliver services to patients.

80.5.3 Hospital Pharmacy Information System

The hospital pharmacy is an important service unit that supports care of patients. Usually the organization of the hospital pharmacy is divided into two parts, one for inpatients and the other for outpatients. The information system of the hospital pharmacy includes an inventory planning and control system that monitors the inventory levels of drugs and purchases drugs whenever necessary to maintain high service quality and low inventory cost of the pharmacy. Besides, the pharmacy information system for outpatients should maintain and manage the dispensing information given by clinicians. However, it should allow immediate changes if some other concerns such as drug interactions occur. For inpatients, the information system should monitor the drug usage of patients, so further therapeutic and billing procedures can proceed based upon this information.

A more advanced pharmacy information system has an embedded knowledge base system to detect the problems of drug interactions and mistaken orders issued by doctors. The pharmacy information system is usually a subsystem of an HIS in modern hospitals. Some hospitals may not maintain a hospital pharmacy for outpatients. However, the dispensing information is delivered through the Internet to drug stores designated by outpatients. In this case, an HL7 or EDIFACT protocol will be needed to provide a standard communication between hospitals and drug stores [80.8]. The current version of HL7 relies on an XML based message syntax. Through XML syntax, a doctor can embed required drug dispensing information, e.g., patient, drug product, dosage, etc., into a message, which is then delivered to the designated drug store.

80.5.4 Nursing Information Systems

According to *Murnane* et al. [80.9], three key nursing information modules are required to successfully deliver nursing care to patients:

1. Care plan
2. Workload allocation
3. Resource scheduling/monitoring.

HIS provides general patient information, and treatment and drug orders from physicians. However, the information is not enough for nursing care as soon as a patient enters into a ward or intensive care unit. To detail the nursing care and utilize the nursing human and equipment resources relies on an integrated nursing information system that can seamlessly interact with HIS. A nursing information system can indicate the relationships among ward, patients, nurse, working shifts, and basic nursing requirements of the patient.

80.6 Medical Knowledge and Decision Support System

MYCIN is an early yet typical decision support system that adopts expert systems, or now called knowledge base systems, in medicine [80.10]. It was designed to diagnose infectious blood diseases, and then to give recommendation on the use of antibiotics. There are only few medical cases like MYCIN in today's medical applications. The reason is that to make a knowledge base useful relies on complete and correct knowledge of medicine. Partial or incomplete knowledge may lead to an incorrect decision, which may guide a doctor to a wrong decision on patient care. Besides, because of the advancing medical knowledge and technology, to keep a medical knowledge base system up to date would be a huge burden for medical doctors and computer specialists in debugging the decision rules. However, medical knowledge and management has improved by information technologies in two aspects: evidence-based medicine and data mining. These two aspects are addressed especially in the following two sections.

80.6.1 Evidence-Based Medicine

Evidence-based medicine (EBM) is defined as [80.11]:

> *The conscientious, explicit and judicious use of current best evidence in making decisions about the care of individual patients, based on an integration of individual clinical expertise with the best available external clinical evidence from systematic research and patient's unique values and circumstances.*

Fundamentals of EBM include three major steps:

1. Knowledge findings based on medical evidence databases
2. Applications of the findings to patients
3. Evaluating the applications and modifying the knowledge findings if necessary.

Knowledge findings usually involve many database and statistical operations on the medical data. Most healthcare journals play a role in publicizing medical treatments and knowledge findings for medical doctors and scientists. Unlike traditional healthcare research that usually involves limited number of cases, by the introduction of digital databases and government support for accumulating patient and treatment records, the number of cases involved in the study based on the government support dataset (e.g., the Surveillance, Epidemiology, and End Results (SEER) program [80.12] and NHIRD of Taiwan [80.13]) is very large. The number of cases can be as large as one million or more. Thus, the reliability of the research results increases, which implies that the reliability of such an EBM is also higher.

80.6.2 Data Mining Techniques

Large-scale medical databases not only increase the reliability of EBM research results, they lead to other potential uses of the data. Traditional EBM studies usually applied statistical tools only. By data mining techniques [80.6], medical researchers are able to find other evidence that usually involve more variables and are not based on testing the hypotheses made in advance by people. Notwithstanding, data mining techniques can be applied to investigate medical improvement and patient relationship management in general hospital management based on the records of patient visits.

Major data mining tools that may help healthcare administration or healthcare services include:

1. Classification tools, e.g., decision trees and neural networks
2. Clustering techniques, e.g., K-Means and hierarchical clustering
3. Association rules, e.g., apropri algorithm and rough sets theory.

Classification is a tool to identify the relationships between certain conditional (independent) variables and a decision (dependent) variable. The relationships are mostly specified to a certain range of conditional variables (e.g., age between 20 and 25 or systolic hypertension above 140 mmHg), and certain range of decision variables (e.g., annual cost of medical care between $ 10 000 and $ 15 000). Because tools of decision trees, such as ID3 and CHAID, provide clear IF-THEN rules for presenting the relationships between variables, they are more acceptable, in comparison with neural networks that define variable relationships as weights on connections of neurons.

Clustering is a tool to separate a data set into multiple subsets. A predefined distance that measures similarity between two cases and methods for finding clusters (subsets of data) are the two key elements in clustering. Clustering does not require a dependent variable. Usually it is applied to handle data with a massive number of variables. Clustering methods (algorithms) iteratively check the distance between cases to find clusters. Basically, the distance between two cases that belong to the same cluster should be shorter than the distance between two cases that belong to two different clusters. The results of clusters are usually difficult to interpret and apply, since distance is an unusual concept in medicine, and the cases of each cluster may include a large number of variables. Even so, clustering has been applied as a technique for analyzing gene expression data in the biological field, e.g., [80.14], and problems of clinical and medical care, e.g., [80.15]. For example, *Jannin* and *Morandi* successfully apply decision tree and clustering techniques to predict parts of the surgical procedure for brain-tumor patients based on the pathology-related characteristics of the patient [80.16].

Tools of association rules intend to find causality between variables. For example, patients who have diabetes are also hypertensive (15%, 90%). The 15% represents support for such a rule, whereas the 90% represents confidence. Support defines the proportion of the number of patients who have both diabetes and hypertension over the total number of patients. Confidence defines the proportion of the number of patients who have both diabetes and hypertension over the number of patients who have diabetes. An advantage of association rules is that they can identify a causality that has less support but high confidence. To search for a plausible curable treatment or medication for rare disorder patients is a typical problem that can apply techniques of association rules, for two reasons. First, rare disorder patients mean that the support is small. Second, if the majority of the patients are cured by a common treatment or medication, its confidence is high. Traditional statistical tools that mostly do not allow a large number of variables in the analysis and count on a large number of samples are not able to handle such a problem.

Though data mining provides an opportunity for finding medical evidence that may not be found by traditional statistical tools, few applications are performed in the healthcare fields. Some researchers ascribe the reasons to a large number of false alarms created by data mining. Actually, the credibility of mining results can be proved by cross-validation or some other related tools [80.17]. From the author's perspective, there are two major obstacles for data mining applications in healthcare. First, healthcare practitioners may not be so familiar with data warehouse and data mining. Second, many legacy medical data tables are not normalized. It is believed that both obstacles will be overcome in the near future, because many multidisciplinary research opportunities have been created for both healthcare and computer science professionals.

80.7 Developing a Healthcare Information System

To develop a good healthcare information system relies on at least three elements: the right people, the right project management, and the right strategic plan. Right people means that the healthcare information system should cover the operation needs of major system users (e.g., administrators, physicians, nurses, staff, patients, etc.) Questions like how many people and what kind of people should be included in the information system depend on the budget and strategic plans of the healthcare organization. The development of a healthcare information system is a complicated project. It usually includes stages of requirement analysis, system design or introduction, system implementation, system tests, user training, and system validation. The range of the project duration depends on the type of information and may be one month to one year. Besides, the people involved in each stage vary. Therefore, a well organized project management is required to ensure that the project can be successfully implemented and applied in accordance with the planned schedule and budgets.

The strategic plan for the healthcare information system has to be set right so it can match the organization's goals and external and internal environment analysis. Because today's HIS plays an important role in patient care and costs much in investment, its success depends on how well it meets the healthcare organization's goal. The steps of the development of a strategic plan for a healthcare information system can be summarized as follows:

1. Perform SWOT (strengths, weaknesses, opportunities, and threats) analysis for the organization.
2. Identify specifically how information systems can strengthen the organization's capabilities to catch external opportunity.
3. Identify specifically how an information system can avoid threats from internal and external environments.
4. Identify healthcare information goals of the organization.
5. Evaluate the gap between the healthcare information goals and current information system.
6. Identify long-term information system objective such that the gap can be filled.
7. Identify resource requirements to fulfill the objective.
8. Make a budget plan for the resource requirements.

80.8 Emerging Issues

The advent of modern medical information technologies has largely improved patient care and the quality of care. More specifically, a healthcare organization almost cannot function without the support of information systems. However, there are still many research issues waiting investigation. Some of them are addressed in the following sections.

80.8.1 Quality of Care

How to utilize information technologies to improve the quality of cares is always an issue. Each time a new technology is introduced, the possibility for improvement of care quality evolves. By means of today's radio frequency identification (RFID) technology, errors in drug dispensing and operation rooms have been reduced because an RFID reader system provides an active alarm when a person, an article, a paper order, a medicine, or a specimen embedded with an RFID tag is not in the right place, right position, and right time that he/she/it is supposed to be. Some case studies even suggested using RFID to monitor the walking routes through wards of medical doctors and nurses, so an alert system may be built to control nosocomial infections. However, side effects of introducing RFID system are inevitable, just like the side effects of introducing barcode systems into the healthcare services [80.18].

80.8.2 Security

Today's healthcare organizations carry a lot of information about patients. Securing the digital data today is as important as securing the paper patient records in the past. Hackers and computer viruses are the two major sources that may jeopardize the safety of patient records. It becomes financial and technical burdens for healthcare organizations to secure large patient-record databases. Some hospitals outsource healthcare information systems to IT companies, so they can ease the technology burden. However, ethical and legal issues may arise if patient records are lost or stolen from those outsourcing IT companies, for any reason.

80.8.3 Public-Use Databases for Medical Research

To attract researchers to get involved in medical studies, many governments are systemically building public-use database for medical research. SEER is a typical database that accumulates cancer patients' records (including demographical, histological, and pathological information). The Taiwan government also allows researchers to retrieve patient records (including demographical information, insurance claims, drug dispensing, and hospital information) for medical studies. Such public-use databases give great opportunities for researchers to investigate prevalence, survival analysis, and other medical comparative studies. Since such studies are performed based on a large number of samples, they can avoid errors resulting from a limited number of samples or data sources. Additionally, more data mining technologies are applied to the databases to handle their multiple dimension data tables.

81. Nanoelectronic-Based Detection for Biology and Medicine

Samir M. Iqbal, Rashid Bashir

This chapter is a review of the work in nanoelectronic detection of biological molecules and its applications in biology and medicine. About half of the chapter focuses on the methods employed to immobilize deoxyribonucleic acid (DNA) on solid substrates with particular focus on the electronic detection and characterization of DNA. Charge-transfer properties and theories are explained, as such electronic and electrical sensing of molecular-level interactions are very important in medical applications for rapid and cheap diagnosis.

A special tool called nanopore, which has been used extensively to characterize DNA, is then reviewed. A special distinction is made between the characteristics, capabilities, and impacts of the biological and the solid-state nanopores. Nanopores, when used in the ion current measurement setup, are used to measure the behavior of DNA as it traverses the nanopore. When the DNA traverses the pore, the blockage of the ion current is observed as a pulse. The statistical analysis of the pulses yields trends that are used to sort the DNA based on various properties. The nanopores are strong prototypes for biosensors, and have become a major experimental tool for investigating biophysical properties of double and single strands of DNA. The DNA sequence can potentially be determined by measuring how the forces on the DNA molecules, and the ion currents through the nanopore, change as the molecules pass through the nanopore.

81.1 Historical Background

Nanotechnology, in the last decade or so, has brought together scientists and engineers from a diverse array of fields to collaborate and share their distinct sets of expertise and tools. The confluence of divergent technologies has provided better handles on nanoscale processes and species. Characterization and control at these fundamental limits have shown immense potential to improve existing technologies and provide better tools for understanding at the most basic levels of nature. This has opened horizons wide open for many diverse areas of research. The major impact it has had, and will continue to have, is in medical applications. Biologists have known for decades that cells and biomolecules are selectively managed, regulated, and controlled, but the tools to organize and direct these interactions are only now emerging, tools to *handle* and integrate synthetic structures in diagnostics and therapeutics. The nascent tools of nanoscience are helping unravel the physics of biological processes in unprecedented detail. The detection and sensing of biological entities has enormous promise, and challenges of correspondence size. The challenges are manyfold: the interface of the wet salty biological molecules to dry cold solid devices, packaging of the devices so that only the sensing part is exposed to the analytes, faithful translation of the biophysical and biochemical interactions into electrical or optical signals, selectivity of the device against the analyte of interest in the pool of thousands of entities of no interest, identification of the useful signal amongst unwanted noise, sensitivity of the measurement system all the way down to the fundamental limits, and repeatability of measurements. For any system to interrogate the few copies of the analyte of interest reproducibly and reliably, the interface also plays a key role. These challenges are the major impediments to the integration of nanotechnology in biological and medical applications.

A few industries that use a combination of engineering, physics, chemistry, and biology in very nontraditional approaches to develop devices for medical applications have very recently emerged. Some examples are on-chip DNA hybridization and optical detection, DNA detection at the nanoscale for diagnostics in medical, military, and food safety applications, etc. DNA carries the genetic information for living organisms and has a special, important place in many areas such as genetic engineering, drug discovery, and gene therapy. The methods used for immobilizing DNA on solid substrates and the electrical sensing schemes will be detailed in ensuing sections in this chapter. As we go along, we will focus on biological nanopores, also known as ion channels, which are integral parts of the living organisms at various levels. These have inherent capabilities for ion-transport regulation under transmembrane potentials. Ion channels have been used to measure the translocation behavior of DNA as it passes through the channel. These form an important framework for DNA detection, but have inherent issues and problems regarding the stability. Solid-state nanopores, direct analogues of the biological ion channels, are then reviewed. Solid-state nanopores are stable under various environments. Cheap and rapid DNA sequencing using solid-state nanopore channels is the focus of a number of major initiatives, owing to the promise of focused and effective treatment of diseases, and fast genetic analysis in areas such as forensics and legal examination.

81.2 Interfacing Biological Molecules

This section is an overview of the techniques used to *probe a single molecule*, i. e., to make a stable and reproducible interface with a biomolecule. It is important to make interface contacts to biological molecules for reproducible and robust interrogation and characterization. Various techniques and chemistries are used to attach biological molecules, such as DNA, to solid substrates, either for conductivity measurements, self-assembly of devices, for bottom-up device fabrications, for patterning matter on the nanometer scale, in biotechnology, and even as biosensors. In the crafty bottom-up paradigm, DNA has played a vital role due to its specific base-pair interactions.

At around the dawn of this century, the major thrust in nanotechnology came from the Moletronics program of the Defense Advanced Research Projects Agency (DARPA) and the National Nanotechnology Initiative (NNI) of the US government. The objective of the Moletronics program is *to develop functioning prototype electronic computer processors and memory integrated on the molecular scale* [81.1]. An important avenue that opened with the vision of Moletronics is towards the development of nanoscale biosensors that are robust, small, accurate, cheap, and have high throughput. A biosensor can be defined as a collection of molecular recognition sites and the transduction components. In case of electrical biosensors, the focus has been on direct measurement of the electrical properties of the molecular interfacing sites. The size of typical organic molecules is in the range of 1–10 nm. To do any realistic electrical measurements through such small objects, we need at least two macroscopic metallic electrodes at the same dimensions.

Self-assembled monolayers (SAMs) of molecules are characterized using a large array of direct analysis tools, but there are few direct label-free characterization tools to quantify or qualify the quality of the surface chemistries or the quantity of immobilized DNA. This is understandable, first due to the complexity of the DNA molecule (that increases even with the addition of a single base); secondly the interactions of the surface chemical properties can greatly change the binding quality of the molecules, which may cause more of the nonspecific adsorption; and thirdly because of the mechanical and chemical flexibility (or instability) of DNA, e.g., hybridization, conformational changes, effect of ambient and temperature, its sensitivity to biologically significant entities, and even to slight changes in chemical composition of the buffer. Notwithstanding the challenges in *driving* DNA, the highest degree of selectivity due to complementarity of bases makes it a molecule of choice in a large variety of self- and mediated-assembly experiments and biosensor applications.

A lot of experiments use physical adsorption to immobilize DNA on a variety of devices. Some approaches use deposition of DNA from a buffer solution using catalysts such as $MgCl_2$ for better DNA adhesion to metal electrodes [81.3]. A receding meniscus of a drying droplet has also been shown towards immobilizing 16 μm long DNA on microstructured surfaces (Fig. 81.1) [81.2]. Imaging techniques such as atomic force microscopy (AFM) are done to confirm the presence of DNA before doing electrical measurements. Passive adsorption of DNA has also been shown in 96-well polystyrene plates by incubation of the molecules with cationic reagents [81.4]. In a similar fashion, a high-frequency electric field has also been used to trap DNA and proteins between the electrode gaps [81.5]. Under the influence of DEP, the DNA is known to be stretched into a long, thin configuration, i. e., it is not randomly coiled. Fluorescence imaging is used to prove the presence of the DNA in the gaps between the electrodes.

By far, chemical adsorption and immobilization is considered the most stable, reliable, and reproducible method to attach biological molecules onto substrates and nanodevices. Usually, the molecules are modified with a functional group(s) that has a high covalent affinity to the surface. Most common and well-studied functional pairs are thiol–Au, biotin–(strept)avidin, and the his–tag system. The complementarity of the DNA strands is also employed extensively, where single-strand (ssDNA) is attached to the surface (called the probe), and complementary ssDNA is supplied from solution (the target).

Gold–thiol is a favorite chemistry of choice for a lot of applications and has been employed in a number of studies to immobilize DNA for conductivity measurements, hybridization detection, sequence detection, DNA-templated self-assembly, etc. [81.6–9]. Glass slides and lately thermally oxidized silicon surfaces are also routinely used to immobilize DNA through various silane-, aldehyde-, and amine-modified schemes. Probe DNA molecules are accordingly modified at the appropriate end(s). The functionalized surfaces exhibit various surface energies (wettability) and/or electrical charges. DNA is chemically anchored on substrate surface either directly to a chemical layer like silane or through a hetero/homobifunctional moiety. Figure 81.2 depicts an example of amine-modified-DNA attachment chemistry through a silane layer on a SiO_2 surface. The attachment of the biological entities has been characterized in various labeled or unlabeled ways, e.g., a recent review has summarized various methods and strategies that have been developed to detect nucleic acids with electrical means [81.10], or, direct optical detection of DNA hybridization on the surface of a charge-coupled device [81.11]. Chemical attachment of DNA has been investigated on various surfaces such as carbon, aluminum, indium-tin oxide, SiO_2, Si_3N_4, and most of all, glass slides [81.7, 12].

SAMs of biological molecules have also been used to make reliable contacts. The networks of polysequences of DNA (DNA with the same base repeated) have been shown to self-assembled onto a mica surface. Poly(dG)–poly(dC) DNA networks showed a *uniform reticulated structure* and poly(dA)–poly(dT) DNA formed a cross-linked network [81.13]. DNA has also been shown to aid the construction of functional cir-

cuits, by constructing Ag wires using the self-assembly of a λ-DNA as a template [81.14]. The λ-DNA was uncoiled and stretched to contact two Au electrodes. The Ag^+ ions were deposited along the DNA, through Ag^+/Na^+ ion exchange as Ag^+ formed complexes with the DNA bases, resulting in nanometer-sized metallic Ag aggregates bound to the DNA skeleton. In a similar approach, DNA-templated assembly of Ag clusters has been shown with electrochemical detection [81.8]. The Ag cations were electrostatically *collected* along the gold-surface-tethered DNA duplex. The Ag aggregates were dissolved and the potentiometric stripping of the dissolved Ag was detected on a thick-film carbon electrode.

81.2.1 Guidelines for Preparing Silicon Chips for Biofunctionalization

DNA is immobilized by physical or chemical adsorption, the latter being more robust and stable in a variety of ambient conditions. A number of chemistries have been shown by various researchers for attachment of DNA via chemical bonds. The motivation for such attachments has been wide, ranging from biosensors to integrated circuits; for the detection of chemical or biological species in biosensors; to controlled assembly of nanodevices and structures in nanoelectronics and biophysical studies.

The general scheme of DNA attachment is through surface functionalization of the substrate and the modification of DNA with a linker end-terminus, as shown in Fig. 81.3. The linker end-terminus can then bind to a hetero/homobifunctional molecule, or the chemical structure of the linker itself is exploited to react with surface functionalized moieties due to certain binding affinities. The bifunctional molecules have at least two available chemically reactive positions, one of which attaches to the surface-grafted molecular layer and the other to the end-linker of the DNA.

Homobifunctional cross-linkers have two identical reactive groups thus can be used in a one-step chemical cross-linking procedure. DNA modified with various end groups or even without end groups has been shown to attach to certain functional groups. Attachment of ssDNA to the surface molecular SAM is mostly verified

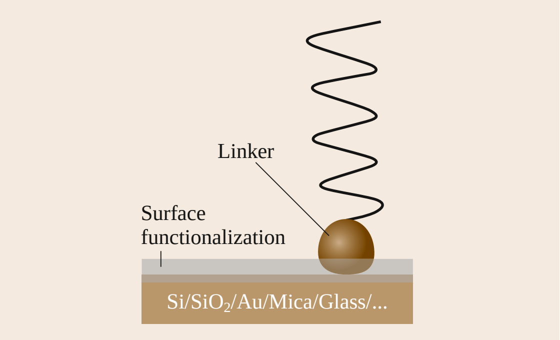

Fig. 81.3 General schematic of DNA attachment via linker molecule

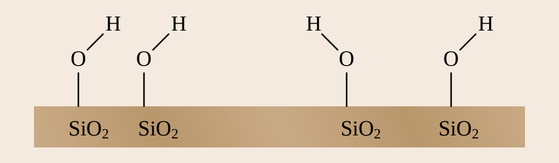

Fig. 81.4 Hydroxylation of SiO_2 surface (after [81.15], by permission of Oxford University Press)

with the fluorescently labeled complementary ssDNA that hybridizes with the adsorbed ssDNA. Other detection schemes involve radioactive dyes such as ^{32}P, phosphor imaging, and chemiluminescence. We present two protocols that can be adapted for covalent attachment of amine-modified DNA to SiO_2 surfaces (adapted from [81.15, 16]).

For direct DNA attachment to the chips, various silanizing agents have been pursued and reported to functionalize SiO_2 surfaces. Generally, the silane-containing chemicals have a tendency to react with hydroxyl groups at the surface of the chips, resulting in silanol groups. The hydroxyl group density at the surface of the SiO_2 thus influences the self-assembly of the silane layer and ultimately the number of attached DNA. The hydroxyl groups on the surface of Si/SiO_2 chips are generally achieved by piranha solution ($H_2O_2 : H_2SO_4$, in various proportions) treatment of the SiO_2 surface, or O_2 plasma etch treatment. Following these treatments, the OH-rich surface of SiO_2 looks as shown in Fig. 81.4.

Exposing the OH-rich surface to a silane results in the reaction of Si of the silanizing chemical with the O group, thus releasing the hydrogen. To directly attach the DNA molecules, an amine modification at the end of DNA can be utilized. The reactive site of the silane (e.g., an epoxide) makes a covalent bond with the amine. The surface coverage of immobilized ssDNA can be verified by using complementary ssDNA tagged with fluorescence. All chip surface processing should be done in a controlled environment, e.g. a glovebox to minimize exposure to ambient moisture and contamination.

For better surface coverage, a homobifunctional linker can be used on top of the surface silane. The chips can be silanized using 3-aminopropyltrimethoxysilane (APTMS), and 1,4-phenylene diisothiocyanate (PDITC) can be used as a homobifunctional agent. Again APTMS hydrolyzes the OH-rich SiO_2 surface thus strongly attached through covalent bonds to it, creating a SAM of amino silane anchors. The amine group at the other end of the APTMS covalently attaches with the C of one of the isothiocyanate groups of the PDITC cross-linker. PDITC has two isothiocyanate sites where its C can react with the NH_2– of APTMS. The other isothiocyanate site on PDITC provides amino-reactive terminus for probe DNA attachment. These PDITC-activated chips are thus immersed in the amine-modified DNA, completing the attachment chemistry for the NH_2-oligo attachment on the SiO_2 surface. The unreacted sites of PDITC are then deactivated by N–N diisopropylethylamine exposure.

81.2.2 Verification of Surface Densities of Functional Layers

The functionalized surfaces can be characterized for adsorbed layers by ellipsometry and contact-angle measurements. The silane layer thickness can be measured by ellipsometry. An isotropic value of $n = 1.50$ for the silane layer and $n = 3.858 - 0.018i$ for the silicon substrate refractive index can be used. The values for monolayers range between 1.45–1.50 in the literature, but this range would give an error of less than 1 Å during measurements. The monolayer thickness can be accurately measured up to ±2 Å. A number of readings should be taken at different places on the chips and compared with control chips.

The hydrophilicity/hydrophobicity of a surface is usually expressed in terms of wettability. Hydrophilicity and hydrophobicity are general terms used to describe relative affinity of materials for water (hydrogen bonding). Hydrophilicity of a surface is a measure of its strong affinity to the water as the polar surfaces form an H bond with water. The opposite hydrophobic surfaces have aversion to water. Contact-angle measurements with deionized water can show functionalized chips to be less hydrophilic than control chips with only SiO_2 and no chemical treatment. The OH-rich surfaces of control chips can make more H bonds with the water and so would be hydrophilic, whereas in relative terms the chemically treated chips would have fewer OH-groups left on the surface and so would be less hydrophilic and can be termed as becoming hydrophobic. A nice example of highly hydrophobic surface is fresh Si surface with no native oxide. Si resists being wetted by water, thus the water forms drops with contact angles $\geq 75°$.

81.3 Electrical Characterization of DNA Molecules on Surfaces

In this section we will review studies on charge transfer and direct measurements of electrical conduction through DNA, along with the various charge transport mechanisms that have been proposed and simulated. It has been established that a number of factors and conditions contribute to the behavior of DNA conductivity [81.17, 18]; the number of base pairs (bp), the sequence and length of DNA [81.3], changes in the distance and angle between bases, the influence of water and counterions, humidity, contact chemistry, surface smoothness, electronic contamination, ambient conditions, temperature, and buffer solution components. The double-helix structure of DNA depends on the hydrophobicity of the bases. The hydrophobic bases turn towards the center, away from the water. The presence of the condensed cations counters the negative charges of the phosphate backbone. The water molecules and cations are thus an integral part of the overall picture and exert nonnegligible forces on the base-pair stack [81.19]. All these factors dictate that DNA is a dynamic and very complex system to simulate owing to its structural, chemical, environmental, and vibrational properties.

81.3.1 Indirect Measurements of Charge Transfer Through DNA

The idea of DNA being electrically conductive can be traced back as far as 1962, when Eley and Spivey hinted at efficient charge transfer through DNA as *... a DNA molecule might behave as a one-dimensional aromatic crystal and show a π-electron conductivity down the axis.* They proposed that the DNA structure was ideal for electron/hole transfer proceeding along a one-dimensional pathway constituted by the overlap between π-orbitals in neighboring base pairs [81.20]. At 400 K, they reported conductivities on the order of $10^{-12}\,(\Omega\,\mathrm{cm})^{-1}$ and energy gaps (ΔE) of about 2.42 ± 0.05 eV. While emphasizing lack of knowledge on the ribonucleic acid (RNA) structure at that time, they reported a similar experimental value for RNA. *Snart*, in 1973, reported a similar and reproducible value of the energy gap (2.4 eV) that was affected by ultraviolet (UV) irradiation [81.21]. Snart's measurement method was very similar to the one employed by Eley and Spivey. These can be considered as the starting points of the quest for DNA conductivity.

In the early 1990s, *Barton* and co-workers performed experiments that suggested long-range electron transfer in DNA [81.22]. The donor and acceptor molecules were intercalated on the DNA strands. When the donor was photoexcited, the fluorescence of the donor was quenched due to electron transfer to acceptor. These results showed very rapid transfer of carriers over > 40 Å via π-stacked base pairs. However other researchers disputed these results, as reproduction of the results with other acceptor and donor candidates was found to be problematic. The starting point of the controversy came the very next year when, in similar experiments, *Brun* and *Harriman* used organic donors and acceptors [81.23] and concluded that charge transfer rates drop off quickly with increasing length of the DNA. *Ly* et al. studied the mechanism and distance dependence of radical anion and cation migration and suggested that the structural flexibility of DNA dictates mixed behavior of hole-hopping and continuous orbital mechanism [81.24]. Such a mechanism in which the injection of charge disturbs the molecular structure is called a phonon-assisted polaron-like hopping mechanism. Such a disturbance in DNA most likely results in the reduction of intrabase distance and unwinding of DNA, giving way to increased π-electron overlap and shift of internal charges inside H bonds. *Giese* and *Wessely*, in 2000, verified these two mechanisms experimentally [81.25]. They reported a coherent superexchange reaction (single-step tunneling) and a thermally induced hopping process for long-range charge transfer, slightly influenced by the number of intercalated adenine–thymine (AT) bases. Generally, in a hopping mechanism, the guanine (G) base is considered the most favorable for landing of holes or trapping, basically because it has the least ionization potential among the four bases: G < A < cytosine (C) < T, independent of nearest-neighbor effects. Since then, more experimental and theoretical research has resulted in seemingly contradictory results.

81.3.2 Direct Measurement of DNA Conduction and DNA Conductivity Models

The sensing of DNA has been a direct result of the electrical characterization studies. DNA has been shown to have metallic-like conductivity [81.26], semiconducting behavior [81.27], and also as an insulator [81.28].

Fink and *Schonenberger* used gold-coated perforated carbon foil as a sample holder to make DNA networks, spanning the holes atop the carbon foil. A low-energy electron point source (LEEPS) was used to image the sample, while a conductive tip contact was placed at the middle of the bundle. They reported an upper value of DNA resistivity of 1 mΩ cm, measured through 600–900 nm-long bundles of λ-DNA in vacuum, concluding that DNA was a good conducting molecular wire [81.26]. *Dekker* and co-workers reported semiconducting behavior of DNA, by measuring the conductivity of 10.4 nm long poly-DNA, electrostatically trapped between two 8 nm spaced metal electrodes, as shown in Fig. 81.5 [81.27]. The first-principles calculations for carrier transport through DNA, as well as experiments performed on 40 nm to 15 μm long λ-DNA suggested exponential decay in conductance with the DNA length [81.28]. In these experiments, electrodes were formed by sputtering gold onto a mica substrate with DNA already immobilized on the surface. Refuting the high conductivity reported by Fink and Schonenberger, similar experiments were carried out and the high conductivity was explained to be an artifact due to electronic contamination from LEEPS. The very next year, these results were challenged by *Kasumov* et al. by their experiments on DNA deposited between 0.5 μm apart rhenium/carbon (Re/C) electrodes [81.29]. The Re/C contacts had superconducting properties. Again, DNA was reported to behave like a metallic conductor. It was suggested that DNA had proximity-induced superconductivity properties at low temperature. It was suggested that the compression caused on the DNA structure due to deposition on surface would change its electronic behavior [81.30]. Simultaneous measurement of the height and conductivity of λ-DNA film formed on mica showed that DNA did not conduct when its height was 1 nm. When the mica surface was functionalized with pentylamine film before DNA deposition, its height was seen to be around 2 nm, and it was conductive. The reduced mica–DNA interaction due to the pentylamine layer ensured that the structure and conductivity was unaffected. *Yoo* et al. measured the conductance through poly-DNA and reported semiconducting behavior with little effect of ambient conditions or vacuum [81.31]. *Storm* et al. reported DNA to be an insulator, as opposed to the previous report of the semiconducting behavior from the same group [81.3]. It was concluded that DNA was insulating at length scales longer than 40 nm and that bare DNA had limited use as a conducting molecular wire [81.32]. The effects of oxygen adsorption on the poly-DNA conductance have also been explored [81.33]. The oxygen content was shown to modulate the resistance. It was also reported that poly(dG)–poly(dC) DNA was a p-type semiconductor and poly(dA)–poly(dT) DNA was an n-type semiconductor. *De Pablo* and co-workers reported a different approach of contactless setup (to avoid possible artifacts caused by the contacts) to investigate DNA electrical properties [81.34]. They reported that the dielectric constant of DNA was similar to that of mica. This study provided a qualitative result of DNA being as insulating as mica.

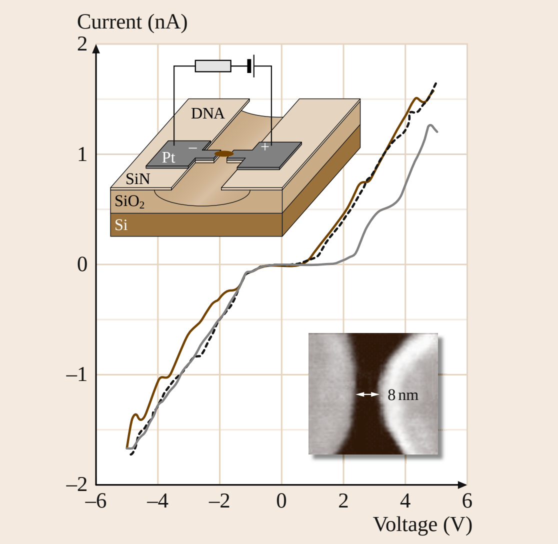

Fig. 81.5 *I–V* curves measured at room temperature on a DNA molecule trapped between two metal nanoelectrodes. Reprinted by permission from Macmillan Publishers Ltd: Nature [81.27], copyright (2000)

A scanning tunneling microscope (STM) tip has also been used to study DNA molecules [81.35]. The STM tip was used to contact the Au electrode in 3 μM thiol-modified dsDNA solution.

Individual molecular junctions were created by moving the tip out of contact with the flat gold electrode with DNA molecules bridging the distance between the tip and the substrate. The conductance showed a series of steps. For 8 bp dsDNA, the conductance histogram showed peaks at near-integer multiples of a fundamental conductance value, $1.3\times10^{-3}G_0$ or $\approx 0.1\,\mu$S, where $G_0 = 2e^2/h \approx 77\,\mu$S. The conductance was also seen to be inversely proportional to the length of $(\mathrm{GC})_n$ sequences (for 8 bp or longer DNA). The insertion of AT bp decreased the conductance with a decay constant of 0.43Å^{-1}. Qualitative differences between the conductivity of ssDNA and dsDNA are also reported, ssDNA being insulating over a 4 eV range between ±2 V, and dsDNA being like a wide-bandgap semiconductor [81.36]. *Iqbal* et al. investigated the effects of the DNA sequence on its conductivity [81.37]. They chemically anchored thiol-modified DNA between gold nanogaps. It was seen that the conductivity through the DNA molecule increased with increasing GC content. Such behavior could be attributed to the increased hole hopping between the hydrogen bonds in the guanine–cytosine pair [81.38]. As the ionization potential of guanine is the lowest ($G < A < C < T$), this would provide the easiest path for the conduction of holes [81.30]. Moreover, the triple hydrogen bonds between the G and C bases as compared with the double hydrogen bonds in the A and T bases putatively result in more paths for the charge flow in higher-GC-content sequences [81.38]. This results in less resistance to the charge flow in the sequence containing more G–C pairs and results in decrease in resistance between various GC-rich sequences by an order of magnitude. They also showed the possibility of using DNA as a reversible fuse, blowing *off* at high temperature and turning back *on* when a conducive environment became available. This was seen by temperature cycling of their devices. Such a framework could also be used as an electrical DNA hybridization sensor. In another report, *Mahapatro* et al. showed that the DNA conductivity scaled with the surface density of chemically immobilized DNA [81.39]. The surface density of the DNA was seen to be higher with high salt concentrations, resulting from better screening of the DNA phosphate backbone charges and reduced electrostatic repulsion. They observed that the conductivity of DNA molecules decreased exponentially as the number of adjacent AT pairs were increased, replacing GC pairs. This also showed that the GC pairs provide a more conductive path to the charge transfer. These finding can have consequences in DNA-based molecular electronics and direct label-free detection of DNA sequence and hybridization.

While the experimentalists have been debating the behavior of DNA, a number of theoretical models have been proposed for the DNA conductivity mechanisms. Almost all the proposed transport ideas rely on the experimental results, and can be broadly categorized as either model simulations or ab initio calculations. The wide variety of these models is understandable due to the large number of variables that affect the conducting properties of DNA. *Jortner* and co-workers suggested two distinct DNA charge transport mechanisms in 1998 [81.40]. They proposed that transport occurs either by the direct unistep hole tunneling from one base pair to another, or by a multistep charge transport through the base pairs, exhibiting a weak dependence on the separation distance between the donor and the acceptor. They further proposed that the charge transport mechanism was determined by the specificity of the intercalating base sequences, which they called bridge. *Yu* and *Song* modeled DNA as a one-dimensional (1-D) disordered system with electron transport occurring between localized states as variable-range hopping [81.41]. These localized states in the sequence would present the candidate landing sites for a hopping electron, while such localization would be enhanced by structural changes in DNA with temperature. They defined a crossover temperature above or below which transport would be either simple nearest neighbor thermal hopping or the carrier would hop different ranges, respectively. Such variable-range hopping mechanism is somehow consistent with the two possible mechanisms proposed by *Jortner* et al. and *Ly* et al. [81.24, 40]. *Yi* modeled the dsDNA molecule as a two-legged charge ladder to render the presence or absence of conductance gaps seen in I–V plots of GC-rich and GC-poor sequences, respectively [81.42]. The gap in conduction plots was explained with strong Coulomb repulsion with eV values much larger than thermal energy. This repulsion is encountered with a screening effect of the cations in the solution. This is a classical example of ab initio calculation. Various reports describing electronic properties of DNA have been published, delving into the coupling strengths between bases, the highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) values and energies, band structures of various dsDNA, effect of doping (specifically, O_2 doping) on conductance, structural effects on conduction, etc. The random and stochastic processes in the complex DNA–electrode system have been identified, explaining the wide claims over values of DNA conductivity (metal, semiconducting, and insulator) [81.43]. As many as 12 parameters have been simulated in adjusting HOMO and LUMO bands in such systems.

Most of the theoretical models assume coherent tunneling to be a major mechanism, with a length (L)-dependent rate of charge transfer R [81.30]

$$R \propto \exp(-\beta L) , \qquad (81.1)$$

where β is the tunneling decay length, the larger β is, the faster the rate of tunneling decreases with increasing distance. There have been various, sometimes contradictory, values reported for β [81.44, 45]. *Berlin* et al. found β to be $0.1\,\text{Å}^{-1}$ for sequential tunneling and about 1 Å^{-1} for coherent tunneling by quantitative analysis using kinetic rate equations [81.46].

The mechanisms proposed in the theoretical models may or may not occur in a system altogether, but there is higher probability for presence of more than one mechanism in any given experiment. The ideal model should take care of the effects of DNA structure, thermal motion of charges as described by classical models, effects of cations in the solution on the structure and on the Coulomb charging, temperature, intermolecular and intramolecular attractions and repulsions, effect of contacting conductors and the chemistries used to contact the DNA, etc. Almost all studies consider charge transport and conductivity on the path along the DNA length. Little, if any work has been done, until lately, on charge transport in the direction perpendicular to the axis of the DNA backbone. *Zwolak* and *Di Ventra* described unique signatures of each base due to their differing electronic and chemical structures [81.47]. They considered a system of electrodes through which a ssDNA passes such that at any given time only one base interacts with the electrodes. Such a system can be visualized as a nanopore made with a very thin membrane, with electrodes on the very edges. With electrode–electrode spacing of 15 Å, they found the ratio of current of A (I_A) and the current of other bases (I_X) to be $I_A/I_X = 20$, 40, and 660 for X = G, C, and T, respectively. This difference in ratios is postulated to stem from relative positions of the Fermi level with respect to HOMO and LUMO, and the density of states at Fermi level. The effects of nearest neighbor were also calculated, with T found to be the most sensitive to such effects. These findings are very interesting as they can be used in conjunction with nanopore measurements of DNA translocation, as will be explained in next section.

81.4 Nanopore Sensors for Characterization of Single DNA Molecules

Biological entities, such as cells, proteins, and DNA, carry charges, and can be forced to move by an electric field in a buffer solution, a phenomenon called electrophoresis. Electrophoresis is usually applied in a gel or capillary to separate biological entities based on their size and charge. Electrophoresis in gel and capillaries has given rise to the idea of characterization by a single pore through which charged entities can be driven. Therefore, characterizations of biological entities by a single pore are actually an analogous application of gel and capillary electrophoresis. The basic design of a nanopore characterization setup consists of two compartments, filled with saline buffer solution, separated by a membrane with the pore, with an anode and a cathode set in each compartment; the pore provides the only path for ionic currents and the electrophoretic movement of DNA or other biological species of interest. When DNA moves electrophoretically from the cathode to the anode, it traverses the pore. As it does so, the ionic current is altered and most typically decreases due to pore blockade. When DNA has passed through the pore, the current recovers to its original level. The characteristics of DNA can possibly be determined from these current fluctuations.

81.4.1 Biological Nanopores

Kasianowicz et al. pioneered the use of a single 2.6 nm diameter α-hemolysin (α-HL) channel [81.48]. α-HL is a protein toxin from the bacterial species *Staphylococcus aureus*. A solvent-free bilayer membrane of diphytanoyl phosphatidylcholine (an artificial lipid bilayer membrane) was formed across a ≈ 0.1 mm diameter orifice. The orifice was in Teflon partition separating two buffer-filled compartments. When α-HL was added to the compartment, it reconstituted into the lipid bilayer, making a channel. A single channel usually formed within 5 min. They used these channels for current fluctuation detection when a single DNA traversed and passed through the pore. The translocation times, or the pulse widths, were proportional to the DNA lengths. A patch clamp amplifier was used to convert current to voltage. In the absence of DNA, applying a potential of -120 mV resulted in ionic currents free of pulses. Following the addition of DNA to the *cis* side of the protein pore, numerous short-lived current blockades occurred (the current was reduced by 85–100%). The blockades lasted from several hundred to several thousand microseconds, depending on the polymer length. For a given polymer length, the total number of pulses was seen to be directly proportional to polymer molar concentration. It was further shown that DNA length, one of the DNA characteristics, was directly proportional to the mean lifetime of the peaks in the signals. This realized determination of lengths of individual RNA or DNA chains using single-channel measurements. Applying the same principle towards a chemical sensor, *Bayley* and co-workers detected organic molecules of relative molecular mass as low as 100 using α-HL pores [81.49]. The innovative step in their study was to equip the α-HL nanopore with an internal, noncovalently bonded molecular *adapter* which mediated channel blocking by the analyte, thus sensitizing the nanopore to specific organic and chemical species. The work showed that β-cyclodextrin (βCD) molecule was sensitive to different guest molecules, as shown in Fig. 81.6. Thus, when bound to βCD, members of the adamantane family of petroleum derivatives could be distinguished, as could the members of the group of tricyclic pharmaceuticals that included imipramine and promethazine. These guest molecules made their presence known by altering the electrical conductivity of the α-HL pore. A single sensing element of this sort could be used to analyze a mixture of organic molecules with different binding characteristics, so that the pore could be in a way *programmed* for range of sensing functions.

Meller et al., extending on the work of *Gu* et al., used the statistical data derived from the patterns of events to show that nucleotides of different sequences could be distinguished from each other [81.50]. Six polymers with the same length but different sequences were measured. Difference between the translocation duration and the temporal dispersion of translocation duration were used to then distinguish between poly(dA)$_{100}$ and poly(dC)$_{100}$ DNA. The translocation times varied among the polymers even if they had the equal lengths, thus different sequences could be discriminated in a mixture. Above 50 °C, the structure of the pore was not stable and measurements could not be performed. In another study, *Bayley* and co-workers covalently attached ssDNA within the lumen of the modified α-HL pores to form a DNA nanopore [81.51]. The ssDNA molecule was attached on the *cis* side of the α-HL channel, resulting in duplex formation with complementary sequences in the internal cavity. The binding of ssDNA molecules to the tethered DNA strand caused changes in the ionic current flowing through the α-HL nanopore. The DNA nanopores were able to discriminate between individual DNA strands up to 30 nucleotides in length differing by a single base. The mean event lifetimes were ob-

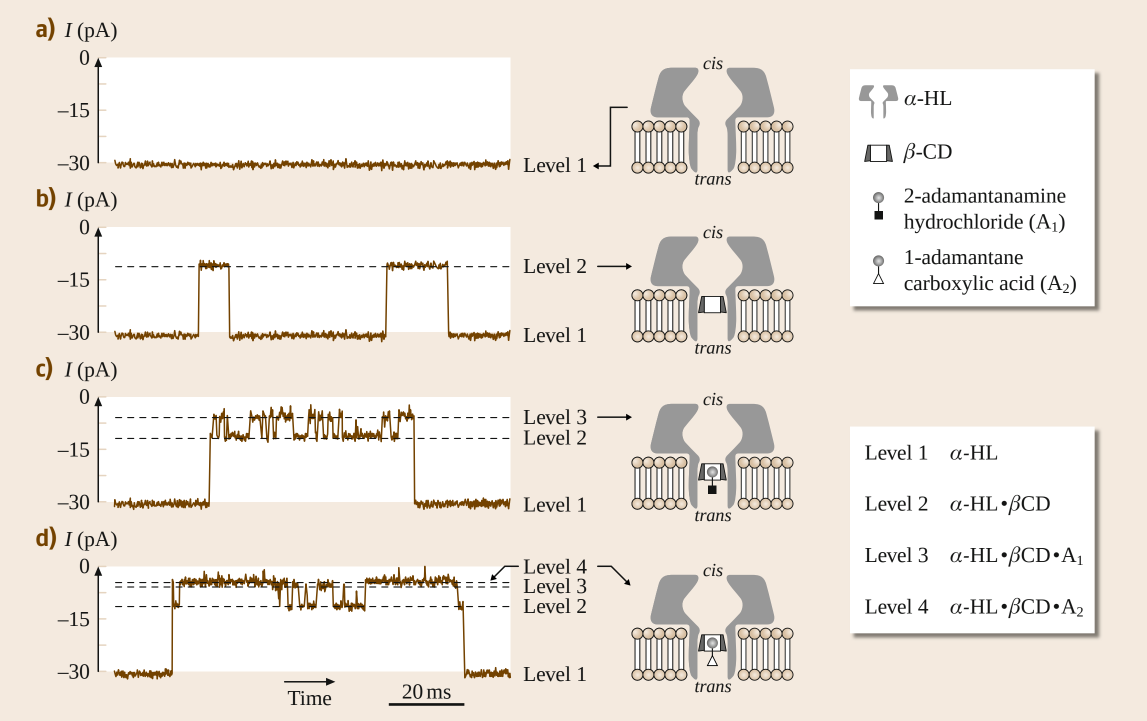

Fig. 81.6a–d Bilayer recordings at −40 mV showing the interaction of a single α-HL pore with βCD and the analytes 2-adamantanamine (A$_1$) and 1-adamantane carboxylic acid (A$_2$). Reprinted by permission from Macmillan Publishers Ltd: Nature [81.49], copyright (1999)

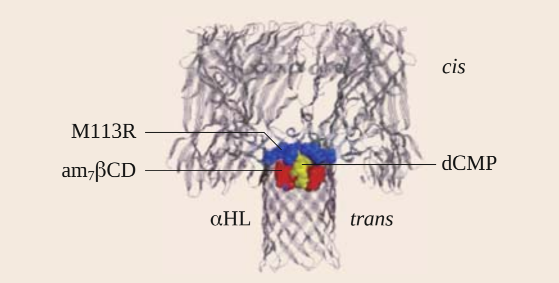

Fig. 81.7 Schematic depicting the α-HL pore, the met-113 substituted with Arg (*blue*), am$_7\beta$CD, and the 2′-deoxycytidine 5′-monophosphate molecule (dCMP). Adapted with permission from [81.52]. Copyright 2006 American Chemical Society

tained by lifetime histogram analysis and it was seen that the type of mismatched base pair influenced the lifetime, and that the mismatch had the most dramatic effect when it was positioned in the middle of the oligonucleotide. Using an array of DNA tethered α-HL pores they sequenced a complete codon in an individual DNA strand. They did not look into any change in the translocation time of a DNA sequence complementary to the tethered DNA as compared with the translocation of the same through an untethered pore. In another report, *Bayley* and co-workers reported another engineered α-HL pore approach to detect individual nucleoside monophosphates (Fig. 81.7) [81.52]. The nucleoside monophosphates are individual bases of DNA (A, G, C or T) with a single phosphate group. The nucleoside monophosphates, like DNA, are also negatively charged thus traverse the pore under the trans-channel bias [81.53]. The α-HL pores were modified with amino-cyclodextrin am$_7\beta$CD as *adapter* and its positive charges altered the translocation time for the nucleosides. They attained accuracy as high as 98% (for G) using this approach.

81.4.2 Solid-State Nanopore

Researchers have been making *point contacts* since as far back as 1977. These were used mainly for material science studies, especially ballistic transport experiments. The schematics of these structures were very much like nanopores, as these stand today, but the aim was quite different [81.54, 55]. The design of current solid-state nanopores was inspired by one such work by *Gibrov* et al. [81.55] and these are the next most ideal replacement for biological nanopores owing to several established and foreseen advantages. First, as for other chemical sensors, sensitive electronic circuitry and photonic sensing capabilities can be integrated directly into a pore–membrane system. Secondly, simultaneous and automated analysis of hundreds of arrays of different channels can potentially be achieved with such an integrated system. Next, they are more robust to withstand wide range of temperature, analyte solution properties, environments, and chemical treatments that might be required for target detection and to eliminate interference. Finally, these can be customized to fit in practical biosensors. These properties have heightened the interest in solid-state nanopores, with particular attention as progenitors of rapid and cheap next-generation DNA sequencing *machines*.

In an earlier report on solid-state nanopores, *Li* et al. utilized a feedback-controlled ion-beam sculpting process to make a nanopore in a silicon nitride membrane [81.56]. A bowl-shaped cavity was made in a silicon nitride membrane and the material was removed from the other side of this membrane using Ar ion-beam sputtering. As soon as the ion-sculpted side reached the bottom of the cavity a hole around 60 nm was opened. Continuous ion-beam exposure reduced the hole to 1.8 nm diameter and ultimately closed it. Two mechanisms were proposed to account for the pore size reduction: surface matter moving due to reduced viscosity to relax the stress caused by implantation, or the creation of adatoms on the surface by incident ions that could diffuse to close the pore. A 500 bp dsDNA translocation experiment was done with a 5 nm diameter pore. Comparative translocation measurements on 3000 and 10 000 bp dsDNA with 3 and 10 nm pores were also reported [81.57]. Longer DNA translocation was noted to be more complex because of folding.

Dekker's group reported the fabrication of a nanopore with electron-beam lithography EBL and transmission electron microscope TEM techniques [81.3]. Their method realized an in situ observation of pore size while the size was precisely controlled at the nanometer scale. *Chang* et al. reported a similar approach, although developed independently [81.58]. They fabricated 50–60 nm long 4–5 nm diameter nanopore channels (NPC), in micromachined Si membranes. The NPCs were fabricated in a double-polished silicon-on-insulator (SOI) wafers. They used EBL to initially define the pore and fabricated 3–4 nm nanopores with standard solid-state processing. The pore was examined visually by using TEM while its diameter shrank to the desired size. The pore shrinkage occurred under an electron beam of high energy. However, their mechanism was completely different from Li's process. In this

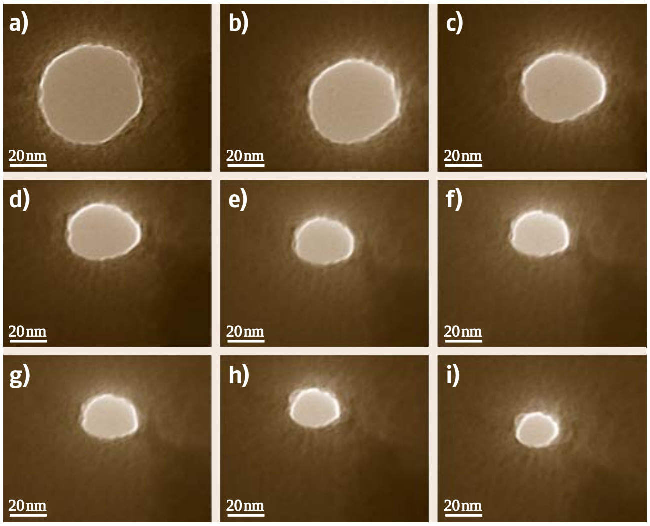

Fig. 81.8 Pore shrinking temporal profile of a nanopore channel ordered alphabetically. All micrographs are taken at 1 000 000 ×. The pore shrinking was stopped at size 16 × 18 nm^2. The pore would shrink further if continuously exposed to the TEM electron beam. The *scale bars* are 20 nm

process, the electron beam (e-Beam) locally fluidized the oxide around the pore, and hence oxide flowed towards the pore and then filled it, as shown in Fig. 81.8. The nanopore die was sandwiched between two silicone rings and placed in a finely milled pocket within Teflon blocks separating the chambers. The Teflon blocks were clamped together and the pore provided the only path for DNA translocation. A 200 bp fragment from the human *CRISP-3* gene was polymerase chain reaction (PCR) amplified and was used for measurements. Ag/AgCl electrodes were used to make the ionic current measurements. As the dsDNA passed through the pore, it modified the bulk and the interface currents, resulting in typical current pulses, but the pulses were upwards, unlike in previous studies. The results were explained, and later confirmed [81.59], by the charge on the DNA which can be detected in the nanopore channel due to an inherent charge amplification. The condensed ions on the DNA backbone amplified the ionic current in conjunction with the mobile surface charges, similar to a field-effect transistor.

Nanopore technology has attracted more attention from a number of research groups in recent years. Research has focused in a variety of directions: towards improving the structures, reducing the time to fabricate, fine-tuning noise parameters, studying the effects of changing voltages, studying force kinetics, exploring conformation changes of molecules, and most importantly the continuous use of nanopores in investigating various biophysical properties of DNA. *Chen* et al. employed atomic-layer deposition (ALD) of alumina to controllably shrink the pore size to required nanometer dimensions. ALD was shown to reduce the noise of the pore and change the surface properties with the passivation effects of deposited alumina film [81.60]. The same group compared dsDNA translocation through nanopores of different channel lengths: nanopore in a thin membrane and nanochannels through a thicker membrane. They showed that DNA of varying lengths (3, 10, and 48.5 kbp) all traveled at the same velocity through both types of nanopores. In contrast to the nonlinearity in mobility versus electric field in gel electrophoresis, they showed that the DNA electrophoretic mobility is independent of the strength of the applied electric field and the length (molecular weight) of the DNA. It is interesting to note here that size separation in gel electrophoresis is based on the length-dependent mobility of the DNA. In another study, the effects of imaging beam of a TEM through nanopores with various geometries have also been studied [81.61]. It was shown that pores smaller than a certain critical size shrank while larger ones expanded, on the same wafer, agreeing with the hypothesis that surface tension effects drove the modifications. The chemical composition in the pore region was also determined, proving that contamination growth was not the underlying mechanism of pore closure. In another approach to make nanopores, *Ho* et al. used tightly focused e-Beam to make nanopores in 10 nm thick silicon nitride membranes [81.62]. They measured the ionic conductance as a function of various conditions and found it to be much larger than the bulk conductivity in case of dilute bath concentrations, whereas it was found to be comparable with, or less than, the bulk for high bath concentrations. These observations were explained in terms of the Debye length, which was larger than the pore radius for the former case. They also reported consistent multiscale simulations using molecular dynamics of the ion transport through the pores. They explained the ion transport by the coupled Poisson–Nernst–Planck and Stokes equations solved self-consistently for the ion concentration, velocity, and electrical potential. The results suggested the presence of fixed negative charges on the pore walls, thus the ion proximity to the pore walls reduced the ion mobility.

In most experiments, DNA translocates the nanopores at speeds as high as 27–30 bases/µs [81.63]. It was reported that the translocation speed could be reduced by controlling the electrolyte temperature, salt concentration, viscosity, and the electrical bias voltage across the nanopores [81.64]. The speed was reduced to 3 bases/μs for 3 kbp dsDNA through a 4–8 nm diameter silicon nitride pore. This significantly reduced the bandwidth requirements on electronic sensing system. However, slowing the DNA also slowed conducting ions, which decreased the current blockage signal. In another study, it was reported that most of the translocation events followed a rule of constant event charge deficit. The experiments compared the distribution of molecular event durations and blockade at various pH values, conclusively demonstrating a large number of long denatured ssDNA translocation in stretched-out conformation [81.65]. The control of the translocation speed and denaturation of dsDNA into ssDNA at high pH is an elegant capability with synthetic nanopores, which would be a challenge with α-HL biological pores. This work showed an ability to detect hybridization from the translocation behavior.

To study pore formation after electron beam deformation, electron energy-loss spectroscopy and high-resolution electron microscopy studies were reported [81.66]. The material composition was studied extensively during pore shrinkage, pore expansion, and pore closure, concluding that pore formation occurred by removal of material at the entrance and exit side of the electron beam. The pore formed had wedge-like edges and contained Si, O, and N. *Heng* et al. investigated the mechanical properties of DNA using translocation of single molecules through the nanopore [81.67]. They used pores with radii from 0.5 to 1.5 nm in 10 nm thick SiN membranes. They also carried out molecular dynamics simulations to explore the stretching and bending of DNA during translocation through such small pores. They reported a pore-dimension- and bias-dependent threshold for translocation. Simulating a 1 nm pore, they calculated forces on DNA to be in the range of 1–300 pN through it and observed the threshold for dsDNA translocation conditioned by its mechanical properties. The same authors also reported the permeation capabilities through various sizes of nanopores by changing the electric fields [81.68]. The electromechanical properties of DNA were studied to define threshold of nanopore sizes that ssDNA or dsDNA could permeate under various electric fields. Previously, the effect of pH on such threshold was also investigated by the same group [81.69, 70]. In the wake of the low-salt current-enhancement studies reported by *Bashir* and co-workers [81.58], *Smeets* et al. reported the effects of salt concentration on ion transport and DNA translocation using 10 nm diameter nanopores [81.59]. They changed the salt concentration by six orders from 1 M to 1 μM, noting a three order of magnitude decrease in ionic conductance, deviating from linear bulk behavior. They carried out 16.5 μm long dsDNA translocation experiments for 50 mM to 1 M salt concentrations, observing downward or upward translocation pulses as a function of ion concentration. They, like *Bashir* and co-workers had explained [81.58], described a model attributing current decreases due to partial blocking of the pore and current increases to the motion of the counterions screening the charge of the DNA backbone. They concluded a threshold KCl concentration of 370 ± 40 mM where two competing effects canceled out. Using the same nanopores, fabrication of point electrodes with radii 2 nm was also reported [81.71]. The nanopores were filled with Au, making conically shaped nanoelectrodes. Metal nanoelectrodes of such high temporal resolution can be used for single-molecule detection and a variety of biological sensors for medical diagnostics. The fabrication of nanopores has also been reported using conventional field-emission scanning electron microscope (FESEM) instead of TEM [81.72]. The irradiation from the electron source of the FESEM showed different shrinking mechanism due to the effects of surface defects under radiolysis and subsequent motion of silicon atoms to the pore periphery. The process was reliable and reproducible, opening the way to parallel fabrication of nanopores in an array format. Another report investigated the ionic current fluctuations associated with the translocation of 1681 bp long DNA as a function of applied electric field. The pulse direction (upward or downward) was investigated to develop a model of DNA counterion ionic current and dipole saturation based on a remarkable work by *Manning* [81.73]. These experiments showed that, at low concentrations, the electrophoretic bias can reverse the pulse directions from upwards to downwards, indicating competition between the mechanical blocking current and the current arising from the condensed counterions on DNA backbone, which saturated at high electric field. The experiments provided a direct way to explore the charge polarization and dipole saturation at the single-molecule level.

Dekker and co-workers have also measured the force on a single DNA while translocating through a nanopore by using optical tweezers [81.74, 75], and ionic transport in electrochemical reactions [81.76]. The optical tweezers were used to slow down and arrest the

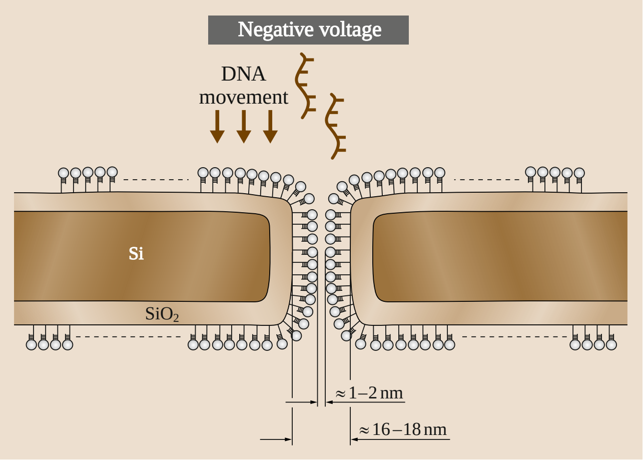

Fig. 81.9 Schematic of the functionalized nanopore channels. The chemical modification and the probe hairpin-loop DNA reduced the NPC diameter. Adapted by permission from Macmillan Publishers Ltd: Nanotechnology [81.77], copyright (2007)

DNA midway through the pore and force measurements were carried out. The study reported effective charge of 0.50 ± 0.05 electrons per base pair, which is equivalent to 25% of the bare DNA charge.

As explained earlier, it is important to slow down DNA to gather more information with reasonable bandwidth requirements on the electronic measurement systems, while still maintaining high signal-to-noise ratio. In a recent report, *Iqbal* et al. chemically functionalized the nanopore channels (NPC) with hairpin-loop DNA [81.77]. The functionalization with known hairpin-loop *probe* ssDNA showed selective transport behavior for *target* ssDNA that was complementary to the probe. This chemical modification of the surface also restricted the movement of the target ssDNA. The hairpin-loop configuration imparted single-base-mismatch sensitivity. Such a single base mismatch between the probe and the target resulted in longer translocation pulses and a significantly reduced number of translocation events. Figure 81.9 shows a schematic of the functionalized NPC and the effective diameter of the NPC after functionalization. They used short ssDNA as target molecules. The target ssDNA were stiff polymers at the length used in this study, thus avoiding the *folding* effect [81.78]. These single-molecule measurements allowed separate measurements of the molecular flux and the pulse duration, providing a tool to gain fundamental insight into the channel–molecule interactions. They discovered that perfectly complementary ssDNA translocated faster and was transported in higher numbers across the pores compared with a target that had even a single base mismatch with the probe molecules. The experimental observations showed that nanopores can be used as selective sensors for genes of interest and that such selectivity could be electrically measured by the translocation signatures at the single-molecule level.

81.4.3 The Promise of Low-Cost DNA Sequencing

The human genome project, completed in 2003, is estimated to have cost US$ 2.7 billion [81.79]. It took more than 12 years to complete. With the advent of novel sequencing technologies and abundant computation power the cost and time needed for sequencing a genome has reduced dramatically, now at ≈ 3 cents/base [81.80]. However, this is an enormous amount for 3 billion bases to be sequenced. Nanopores, in spite of their shortcomings and open challenges, are a hope to achieve the US$ 1000/genome target as set by the National Institutes of Health with more than US$ 70 million in grant monies. The challenges of nanopore technology are both material and electrical. The reproducibility of the nanopore channels is a concern where even an angstromical difference in channel length changes the conductivity of the pore and hence the baseline currents. Although the baseline can be normalized, the noise varies from pore to pore owing to the differences of physical and chemical properties of the pore wall surfaces. There are also issues of bandwidth; DNA passes way too fast for the electronics readout to capture the full details of translocation. The best optimal bandwidth of measurements would still miss too many fast translocation events, significantly skewing the analysis of the pulse behavior, while reducing the noises. The bandwidth issue thus limits the speed of classifications that can be made with nanopores. There are a number of noise sources that are encountered in nanopore measurements; especially $1/f$ (flicker) noise. Tackling such diverse scientific challenges in the nanopore measurements is an uphill task. However, the promise of cheap and fast sequencing machines makes every effort worth pursuing.

81.5 Conclusions and Outlook

This chapter summarized the state of the art in probing the electrical properties of molecules with special emphasis on DNA conductivity. The various techniques for DNA immobilization were discussed. The biological ion channel pores extended to the idea of solid-state nanopore, and the state of the art in nanopore fabrication and its applications, were covered. Very recently, two review articles have appeared [81.81, 82] that cover the history and state of the art of the nanopore research in more detail. For details of laboratory protocols of setting up biological and synthetic nanopores for DNA analysis, a laboratory manual appeared in December 2007 [81.83]. It is the consensus that nanopores have set some ambitious goals for the research community, foremost being the sequencing of the human genome for less than US$ 1000 dollar. The confluence of the sophisticated electronic sensing and nanopore detection techniques has strong potential of achieving the US$ 1000 genome and much more.

82. Computer and Robot-Assisted Medical Intervention

Jocelyne Troccaz

Medical robotics includes assistive devices used by the physician in order to make his/her diagnostic or therapeutic practice easier and more efficient. This chapter focuses on such systems. It introduces the general field of computer-assisted medical interventions, its aims, and its different components, and describes the place of robots in this context. The evolution in terms of general design and control paradigms in the development of medical robots are presented and issues specific to that application domain are discussed. A view of existing systems, ongoing developments, and future trends is given. A case study is detailed. Other types of robotic help in the medical environment exist (such as for assisting a handicapped person, for rehabilitation of a patient or for replacement of some damaged/suppressed limbs or organs) but are outside the scope of this chapter.

82.1 Clinical Context and Objectives

Informatics and technology have dramatically transformed clinical practice over the last decades. This technically oriented evolution has run parallel to other specific evolutions of medicine:

- Diagnostic and therapy procedures tend to be less and less invasive for the patient, aiming at reducing pain, postoperative complications, hospital stay, and recovery time. Minimal invasiveness results in smaller targets reached through narrow access (natural or not) with no direct sensing (vision, touch) and limited degrees of freedom.
- More and more data are handled for each patient (e.g., images, signals) in order to prepare and monitor the medical action, and these multimodal data have to be shared by several participating actors.
- As in many other domains, quality control gets increasingly important and quantitative indicators have to be made available.
- Traceability becomes mandatory, especially regarding the ever-increasing number of legal cases. Traceability is also of primary importance in cost management.

These evolutions make the medical action increasingly complex for the clinician, at both the technical and organizational levels. Computer-assisted medical intervention may contribute a lot to those clinical objectives.

They may provide quantitative and rational collaborative access to patient information, fusion of multimodal data, and their exploitation for planning and execution of medical actions.

82.2 Computer-Assisted Medical Intervention

The development of this area from the early 1980s results from converging evolutions in medicine, physics, materials, electronics, informatics, robotics, etc. This field and related subfields are given several almost synonymous names: computer-assisted medical intervention (the most general), augmented surgery, computer-assisted surgery, image-guided surgery, medical robotics, surgical navigation, etc. We will use the term *computer-assisted medical intervention* (CAMI) herein for this domain.

We define CAMI as aiming to provide tools that allow the clinician to use multimodal data in a rational and quantitative way in order to plan, simulate, and accurately and safely execute mini-invasive medical interventions. Medical interventions include both diagnostic and therapeutic actions. Therapy may involve surgery, radiotherapy, local injection of drugs, interventional radiology, etc. (Some of these medical terms are explained in a glossary located at the end of this chapter.)

82.2.1 CAMI Major Components

CAMI [82.1] may be described as a perception–decision–action loop, as presented in Fig. 82.1. The perception phase includes data acquisition and processing, the development of specific sensors, and their calibration. Data may be acquired pre-, intra- or postoperatively. Images may provide anatomical information or functional one; data provided by the sensors may be one-dimensional (1-D), two-dimensional (2-D), three-dimensional (3-D, sparse or dense) or four-dimensional (4-D, i.e., varying with time). Each imaging sensor brings its specific type of information and multimodality is in general necessary. The need to assist the intervention in a quantitative and accurate way requires the calibration of sensors enabling both the transformation from image coordinates to spatial coordinates and the correction of possible image distortions. Specific sensors such as position sensors (also called localizers) and surface sensors have been integrated into CAMI components. Localizers give access to position and orientation of objects (instruments, other sensors, anatomical structures such as bones). Surface sensors give access to the external surface of an object (an organ, for instance). All those information are potentially useful to plan and control the execution of a medical action.

The main objective of the decision stage is to build an integrated numerical model of the patient and, in some cases, a model of the action. As mentioned previously, many types of information may be useful: data provided by imaging sensors, for instance, but also a priori medical knowledge (for instance, statistical data about organ shapes or occurrence of pathologies, biomechanical models of the limbs, etc.). One very important stage is data fusion, also called registration, which corresponds to the action of representing all the information in a single reference frame. Registration, and in particular medical image registration [82.2], has been a very active domain for three decades. From this integrated model, the medical action can be planned; for instance, one may have to determine the type, size, position, and orientation of a knee prosthesis that provides the best alignment of hip, knee, and ankle joints; or one may decide which number, shape, intensity, position, and orientation of radiation beams would allow to radiate a tumor of a given shape, with a given dose, whilst sparing organs at risks. Planning may involve highly interactive tools where the clinician navigates in the data and specifies the selected strategy. It may also include optimization tools when the medical goal

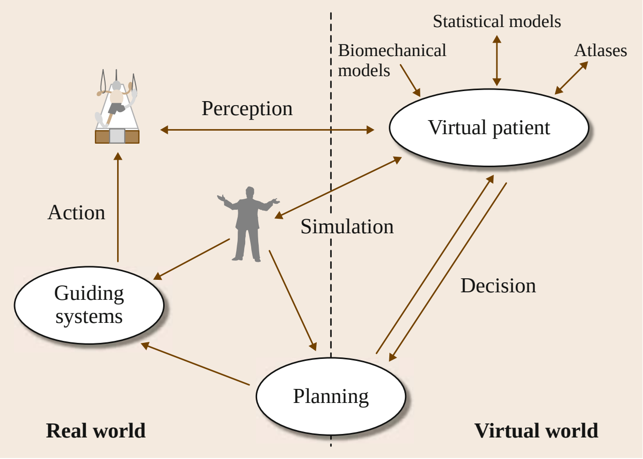

Fig. 82.1 CAMI methodology

can be specified as an optimization problem (radiotherapy planning is an excellent example). In some cases, planning may be very difficult and simulators could provide help for the computation of the clinical outcome of a selected action; for instance, when a bone fragment has to be moved in the patient's face, it may be very useful for the surgeon to foresee the functional and aesthetic consequences of this gesture on soft tissues [82.3]. Registration and planning are included in the decision stage.

Action requires accurate execution of the planned intervention. Often, a registration stage is necessary to transfer the planned action to the interventional conditions; for instance, the action is planned from preoperative data, e.g., magnetic resonance imaging (MRI), and must be registered to the real patient in intraoperative conditions. Two main types of assistance exist: navigational aids and robots. In the first case, the action is monitored using suitable sensors such as localizers; information is rendered to the clinician about the planned and executed actions. The clinician makes use of this information to control his/her action, such systems are called *passive*. The first surgical navigators have been used for neurosurgery [82.4, 5]. The action can also be performed more of less autonomously by a robot. The first application of a robot in CAMI took place around 1985; the application field was also neurosurgery. The medical robot needs to be connected to patient data and models in order to be able to transfer the planned intervention to the robot coordinates; this is the robot registration problem. The medical robot is therefore always an *image-guided robot*.

Simulators may also be developed for training purposes. The advantages are the abilities to provide frequent and rare medical cases, to gain realistic experience with lower stress than with real patients, and to quantitatively evaluate the practitioner. This may facilitate the acquisition of new medical skills, with new techniques and/or tools. This can also be considered a very valuable component of CAMI.

Based on numerical data, tracking of objects (instruments, sensors, and anatomical structures), and positioning of tools with navigation or robotized aids, those CAMI procedures are fully traceable.

82.2.2 Added Value of a Robot

Automation is generally not a primary goal of medical robotics, where the interaction with a clinical operator has to be considered with a very special attention. Indeed, most often medical robots are not intended to replace the operator but rather to assist him/her where his/her capabilities are limited. In general CAMI systems are considered only as sophisticated tools in the hands of the clinician.

In medicine, like in many other application areas, the advantages of the robot are its precision, ability to repeat a task endlessly, potential connection to computerized data and sensors, capability to operate in hostile environments [biological or nuclear contaminations, war or catastrophe areas, space (orbital station) or undersea (submarine), etc.] where clinician presence or abilities may be limited and humans may need medical care.

Navigational aids have already demonstrated their clinical added value in various specialties (neurosurgery, orthopaedics in particular) and their integration in the clinical environment is generally easier than for a robot. Safety issues are also more limited. Moreover navigation systems are very often more cost effective. These are the reasons why it is very important to use a robot only for clinical applications where it can offer functionalities that the navigation system cannot; potential specific robot abilities are:

- To realize complex geometric tasks (for instance, to machine a 3-D bone cavity)
- To handle heavy tools (e.g., radiation apparatus) or sensors (e.g., an intraoperative surgical microscope)
- To provide a third hand to the clinician
- To be remotely controllable and to offer scaling capabilities in terms of transmitted motions or forces
- To filter undesired movements (such as physiological shaking in teleoperation)
- To be force-controllable down to very small force scales
- To execute high-resolution high-accuracy motions (for microsurgery)
- To track moving organs and synchronize to external events based on some signals
- To be introduced into the patient for intrabody actions.

Another aspect that will be further discussed is the absolute necessity to demonstrate the clinical added value of the system, i. e., to prove that it brings a clear clinical benefit at some level (for the patient, hospital, or healthcare system).

82.3 Main Periods of Medical Robot Development

Early medical applications of robotics are characterized by transferring to this domain accurate and automated tool positioning capabilities of robots originally developed in industrial applications.

82.3.1 The Era of Automation (1985–1995)

As mentioned previously the first surgical robots were introduced in neurosurgery. Neurosurgery already had a very long tradition of minimal invasiveness and use of computerized 3-D imaging data; indeed, the first computed tomography (CT) scans in the early 1970s were performed for brain imaging. Stereotactic neurosurgery is a particular type of minimally invasive procedure which consists of *blindly* introducing a linear tool into the brain through a keyhole (3 mm diameter) for biopsies, removal of cysts or haematomas, placement of stimulation (Parkinson disease) or measurement (epilepsy) electrodes, etc. Conventionally, stereotactic neurosurgery is performed with the help of a stereotactic frame whose functions are to immobilize the patient skull, register preoperative data to the intraoperative situation (the frame is installed on the patient's head before the preoperative examination), and finally to offer mechanical guidance for tool insertion. Except for the first function, a robot can advantageously replace the frame: it is easily connected to imaging data, is less invasive, and may offer a larger range of trajectories for tool positioning. Anthropomorphic robots associated to stereotactic frames or robotized stereotactic frames have been developed and clinically evaluated in the early 1980s (for instance [82.6, 7]). Reference [82.7] describes the accurate positioning of a guiding tool with respect to preoperative data in a stereotactic neurosurgery application using a Puma 260 robot. The cited paper reports a series of 22 patients. While [82.8] presents a CAMI system integrating a modified industrial robot (reduced speed, nonbackdrivable joints) for a similar application. The first patient (Fig. 82.2a) was operated on with this system in 1989 and since then hundreds of patients have been treated with this technology. This system was the academic precursor of the Neuromate product (Fig. 82.2b) with which thousands of patients were treated. These systems are called *semi-active* because the robot is only a guiding device and the gesture (drilling the skull and inserting the needle) is still performed by the surgeon through a mechanical guide positioned by the robot.

Reference [82.9] proposed an automated view of the whole process of stereotactic neurosurgery: a robot equipped with different types of tools in a tool-feeder effector was installed in a CT room; after imaging data and planning, the robot performed the drilling of the bone and the placement of the surgical tool. CT enabled repeated image control. The robot was specifically designed for this application. The first two patients were operated in 1993. Eight cases of biopsies are reported in [82.9]. As far as we know, this system has not been extensively used in clinical routine.

In orthopaedics, the placement of prostheses requires the preparation of the bones; for instance a cavity has to be drilled before inserting the femoral component of a hip prosthesis; similarly, planar cuts have to be realized on the tibia and femur extremities in order to place knee prosthesis components. Thus, such stages of the interventions are very close to machining a mechanical part: a 3-D shape has to be accurately realized by sawing or milling with given position and orienta-

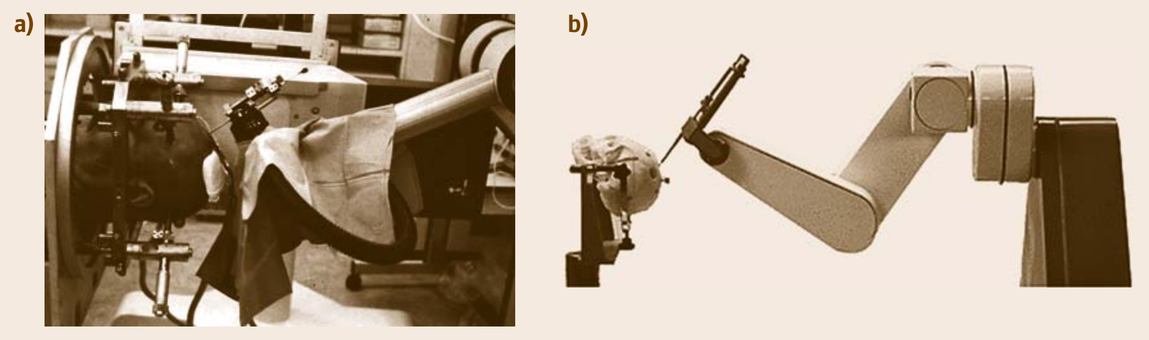

Fig. 82.2 **(a)** Grenoble robot for neurosurgery (TIMC laboratory and Grenoble University Hospital) and **(b)** the Neuromate industrial version

tion. This is why the idea of using a robot came very naturally for such tasks. Robodoc [82.10, 11], used for cavity preparation in total hip arthroplasty, was developed from 1986 first in a laboratory setup. Then, from 1989 to 1991, 29 dogs were operated with the help of the system. The first ten patients were included in a Food and Drug Administration (FDA)-approved clinical research trial between 1991 and 1993; very large series of patients for comparison of traditional interventions with Robodoc-assisted ones were included from 1995 to the early 2000s. Thousands of patients benefited from the use of Robodoc. Robodoc is *active* in the sense that a part of the surgical action (machining the bone) is performed autonomously by the robot under surgeon supervision. Several other systems were developed based on a similar approach.

The underlying idea in this first period was that surgical subtasks such as accurate positioning of a tool or machining, based on numerical data, could be transferred to a robot and automated to a certain extent.

82.3.2 The Era of Interactive Devices (1990–2005)

Whilst the automation era focused on rigid and nondeformable anatomical structures, the second era is characterized by the development of more interactive control schemes for complex tasks, in particular for interventions on soft tissues.

Indeed, in the two previous examples (Sect. 82.3.1), the anatomical structure of interest is rigid and nondeformable; in the case of stereotactic neurosurgery, the brain is accessed through a small hole. The trajectory through the hole is simple (a linear tool is inserted to a given target). Brain motion and deformation can be neglected and the skull is immobilized. As regards orthopaedics, bones are not deformable and can be fixed to external fixtures to avoid any motion. Obviously there are much more clinical situations where the procedures are more complex and concern soft, mobile, and deformable tissues. For such applications automation is often still out of reach or may not be the preferred solution, for instance, when the expertise of the clinician is so complex that it cannot totally be transferred to the robot.

In contrast to earlier automated robot control, robotic development in the mid 1990s was characterized by more direct operator control. In particular, efforts were applied towards teleoperation; this form of robotic application was traditionally used in the nuclear industry. In this situation, the surgeon is totally in control of the surgical tool through a master–slave apparatus. The distance between the master and slave components is highly variable: although the main use is for very close teleoperation (in the same room), some very long distance (thousands of kilometers) experiments have taken place. The function-transferring movements from the master to the slave may involve scaling down (forces and/or motions) and filtering. The main clinical applications are in endoscopic surgery where instruments and optics are introduced into the patient's body through small incisions. Those entry points limit the instruments' possible motions [four degrees of freedom (DOFs) instead of six] and the surgeon has to operate under video control. In a first stage, the motion of the optical system – the endoscope – alone was robotized: instead of requiring one assistant to move the endoscope for hand–eye coordination, the robot is controlled by the surgeon himself/herself by different means: voice control (AESOP [82.12]), head movements (Endoassist [82.13]) or high-level image processing software (Sect. 82.4). More recently the displacement of instruments has also transferred to robots, potentially offering extra DOFs; this is the case of the DaVinci multi-arm system that offers intrabody DOFs of the instruments [82.14].

From the mid 1990s synergistic devices [82.15] also named *hands-on* robots [82.16] were proposed. The rationale for such systems is that the clinical application is generally so complex that it can only be partially embedded in numerical models and data. Therefore relying both on the clinician for his/her very high skills, capacity of judgement, intelligent perception, and on the computerized robot for its quantitative knowledge of the planning, accuracy, and sensors is potentially very fruitful. In the PADyC [82.17, 18], Acrobot [82.16, 19], and Makoplasty [82.20] systems, the surgical tool is attached to the robot effector and the surgeon holds it. The motions proposed by the human operator are filtered by the robot in order to keep only the part of the motions which is compatible with the surgical plan; for instance, the tool has to keep in a plane or in a given region. Different technologies implement this principle of constrained motions: clutchable freewheels, backdrivable motors, controlled brakes, etc.

82.3.3 The Era of Small and Light Dedicated Devices (2000 to Present Day)

This era tends toward a miniaturization of robots up to the stage where they can be attached to a body

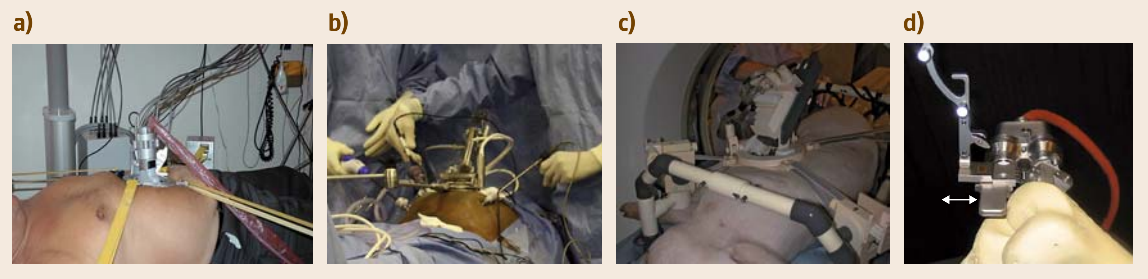

Fig. 82.3a–d On-body and on-bone robots at Grenoble: **(a)** TER slave robot for tele-ultrasound examination (TIMC, Grenoble University Hospital); **(b)** LER-Viky endoscope holder (TIMC, EndoControl-Medical Company, Grenoble University Hospital and Paris La Pitié Salpétrière Hospital); **(c)** LPR MRI- and CT-compatible robot for image-guided punctures (TIMC, Grenoble University Hospital); **(d)** Praxiteles robot for total knee arthroplasty (PRAXIM, TIMC, Brest University Hospital)

part, inserted into the patient's body or integrated into mechatronic surgical instruments.

In systems presented in Sects. 82.3.1 and 82.3.2, the robot mechanical architectures were inspired by traditional industrial robotics: general-purpose anthropomorphic six-DOF (or more) arms are used. Systems are very versatile and can adapt to a variety of tasks. However, this generality has a cost: these robots are also very often quite cumbersome and are attached to the floor, bed or ceiling. Their working space may be quite large and not easily manageable in an operating room (OR) that offers limited space and in which people (patient and staff) are very close. This is why new generations of robots have been specifically designed and developed for limited application areas.

This new generation of systems has produced robots so small that they can be supported by the patient body or attached to one of his/her bones. Because of their size these robots are more easily integrated into the OR and are designed to be very well suited to a specific task. These two factors offer potential advantages over traditional systems by providing a safer operating environment and cost effectiveness. The Grenoble Techniques for Biomedical Engineering and Complexity Management (TIMC) laboratory was a pioneer in small-scale robotics, and Fig. 82.3 illustrates four such pioneering works. TER [82.21] (Fig. 82.3a), a robot for tele-ultrasonic examination, has been clinically validated for remote examination of abdominal aortic aneurysm and for emergency care of abdominal traumas; LER [82.22], a light endoscope holder, has been validated on pigs and corpses, and VIKY, the corresponding industrial product (Fig. 82.3b) is European Community (EC)-marked and has been used on patients; LPR [82.23] (Fig. 82.3c), a CT/MRI-compatible robot for punctures, has been validated for CT on pigs and for MRI on volunteers (but without puncture); Praxiteles [82.24] (Fig. 82.3d), a robot for total knee arthroplasty, has been validated on corpses and recently entered multicentric clinical evaluation on patients.

Following the same philosophy, the Mars system (now called Mazor [82.25], a product) is presented in detail in Chap. 78. It is being clinically evaluated on patients for spine surgery. This list of *body-supported* or *bone-mounted* devices is not exhaustive.

Other systems are sufficiently small to be completely introduced into the body of the patient. Some groups focus on locomotion issues; for instance, several versions of an inchworm-type compact robot that moves inside the intestine have been proposed [82.26]. The aim is to replace the long, quite rigid, and painful endoscope traditionally used in colonoscopy; experiments on pigs have been carried out successfully. With a rather similar locomotion principle, a robot that moves on the surface of the heart has been developed [82.27]; experiments on live animals have been carried out. A robot rolling on soft tissue organs in the abdomen has also been described [82.28]; this robot carries a camera and experiments on animal organs have been carried out. Finally, a smaller and simpler device actuated from outside of the body using external magnetic fields has been proposed [82.29]; such a robot would be injected into the eye, for instance, for drug delivery to retina vessels.

Other research groups aim at giving extra DOFs to traditional instruments: the domain of active catheters that can adapt actively to vessel curvature has been investigated for several years [82.30, 31]. Recently, some of these systems have reached the market (Table 82.1). Finally, the field of articulated tools for endoscopic surgery is also very active; the aim is to develop surgical

Table 82.1 Industrial medical robots

System name	Clinical specialty	Type	Last distributing company	Estimated number of installed systems	Status
Neuromate	Stereotactic neurosurgery	Semiactive (mechanical guide)	Schaerer Mayfield	$15 < \mathrm{nb} < 20$	Unknown
PathFinder	Stereotactic neurosurgery	Semiactive (mechanical guide)	Prosurgics Ltd.	Unknown	Unknown
Surgiscope	Microsurgery	Surgical microscope holder	ISIS	$15 < \mathrm{nb} < 20$	No longer distributed
MKM	Microsurgery	Surgical microscope holder	Carl Zeiss	Unknown	No longer distributed

tools equipped with intrabody DOFs to recover full mobility of the tools with respect to the organs. The specific area of intrabody devices raises very challenging issues related to biocompatibility, safety, power supply, and data transmission. Smart pills such as the M2A [82.32] or Norika [82.33] ones, which are swallowed by a patient and enable visualization of the gastrointestinal track, do not yet integrate active devices but can be seen as precursors of future highly integrated mechatronic intrabody devices.

82.4 Evolution of Control Schemes

Evolution from *bone applications* to soft tissues also resulted in the evolution of control schemes providing a more active role for the surgeon or aiming at a real-time perception–decision–action control loop.

A large number of the oldest systems integrate a *single-shot* perception–decision–action process; for instance a planned trajectory is selected from CT data and transferred to the intraoperative conditions after registration of preoperative to intraoperative data. To guarantee that the plan is still valid intraoperatively, the anatomical structure of interest must not move. This approach has been largely used for neurosurgery and orthopaedics surgery; in both cases the structure is fixed using a stereotactic frame or external fixtures. The operator is often limited to the role of a supervisor when the robot moves the tool.

More recently (Sect. 82.3.2) the operator has been given a more active role in the execution of the task. In the case of *comanipulation* the robot and the operator participate simultaneously to the motions of the tool. In the Acrobot system [82.19] the proportional–integral–derivation (PID) coefficients of the control law are given by functions that depend on the position of the tool with respect to a region of allowed motions, which corresponds for instance to the bone to be removed for prosthesis implantation: inside the region, the motions proposed by the operator and detected by a force sensor are transmitted to the tool without significant modification; in an intermediate region the motions are more or less transmitted depending on their direction; motions outside the planned region are strictly forbidden. The Steady Hand [82.34] works similarly: the operator manipulates a handle and proposed motions are detected. In contrast to the Acrobot, the Steady Hand does not select permitted directions of motions but rather scales down motions and forces for microsurgery or biology applications. In the case of PADyC the principle is slightly different [82.17, 18]; PADyC is a passive arm for which each joint is equipped with two freewheels than can be independently clutched or unclutched using a motor; the motor is velocity controlled, and this velocity determines the range of allowed motion of each joint in each direction at each instant. This range of motion is computed from the representation of the task (position to reach, trajectory to follow or region to keep inside for instance) and from the current position of the robot. No force sensor is necessary. For teleoperation, the operator interacts with a master device and the slave robot reproduces the motions proposed by the operator. Transfer functions may enable scaling and filtering of disturbing shaking motions like in the DaVinci. Teleoperation can integrate a force feedback to the operator like in the Sensei system for endocardial robotized catheter control.

Few systems integrate hybrid force–position control of the robot. One application case is external ultrasound examination, which requires constant contact of the ultrasonic probe on the body of the patient. Thus several robotic systems for ultrasound examination (remote or automated) have been developed with a hybrid control scheme [82.35, 36]. They generally combine position control in the main direction of motion with force control in order to maintain contact during probe motion. Dermarob [82.37], developed for skin sampling for skin grafts in burnt patients, follows a similar hybrid control scheme.

Some of the systems developed for orthopaedics and neurosurgery offer some basic tracking abilities using a localizer and markers attached to rigid structures of interest. This is, for instance, the case of Caspar, which is used for ligamentoplasty in knee surgery, and the case of a frameless version of the Neuromate. Systems such as Mazor or Praxiteles which are mounted on the anatomical structure of interest move with it and therefore suppress the tracking problem. Recently other systems have been developed with evolved abilities for tracking of soft tissues. Instead of having a fixed target, the robot has to track it in real time, in general from information extracted from imaging data. Typical examples are related to organ motions induced by cardiac or respiratory cycles. In those cases, a real-time perception–decision–action loop must be developed. The Cyberknife system (Sect. 82.5) developed for radiotherapy [82.38, 39] determines the current position of a tumor moving with patient respiration by using external markers localized in real time [82.40, 41]. Alternative approaches consist of coupling motion in the image information to motion of the robot at a low level through visual servoing. Pioneer work was described in [82.42]; from high-speed camera data, the motion of relevant fiducials on the heart surface was computed and fed back to a slave robot for teleoperation, giving the operator the feeling of a stable target. More recently several groups have applied visual servoing to image-guided minimally invasive actions. Video images are used for robotized endoscopy [82.43,44]; ultrasonic images have also been introduced [82.45, 46] for cardiac and vascular applications. Directly coupling motion detection in the images to motion of the joints requires very careful robustness analysis.

82.5 The Cyberknife System: A Case Study

This system is described in more detail to make the intrinsic complexity of a robotic CAMI system a bit more visible. This section is also intended to introduce the potentially long road from an initial paradigm and a first prototype to a clinically used product. Specific issues relating to medical robotics and explaining this long road are discussed in Sect. 82.6.

The Cyberknife system, distributed by Accuray Inc., has been developed in the context of radiotherapy. Usually, when treating a patient with conventional linear accelerators, the patient is positioned onto a couch that has four main DOFs (three translations and one rotation), and the linear accelerator allows orientation of the radiation beam using two more rotational DOFs. The convergence point of the radiation beams is termed the *isocenter*. A reference frame R_{iso} centered on this point is associated with the complete radiation system. The DOFs enable positioning of the tumor on the isocenter and orientation of the radiation beams properly with respect to the tumor in order to execute the planned treatment (Sect. 82.2.1). In practice, due to the complexity of positioning the patient and orienting the beams with such machines, treatments generally consist of rather simple ballistics with rather few radiation beams. The Cyberknife concept proposes to install the radiation source on a six-DOF robot in order to avoid repeated combined motion of the couch and linear accelerator. This enables the execution of complex treatments with hundreds of beams distributed around the tumor without having to move the patient. Using such a large number of small beams enables sculpting of the dose distribution to the tumor shape with high accuracy.

The first version of the Cyberknife [82.38] was installed at Stanford Medical Center in February 1994, and the first patient was treated with the system on June 8, 1994. The current version of the system integrates a Kuka robot (Fig. 82.4a). In early May 2008, the Accuray Company reported 134 installed systems worldwide and 40 000 patients treated, mostly for brain, spine, lung, prostate, liver or pancreas tumors.

Regarding patient data, preoperative CT is traditionally used for treatment planning; other modalities can

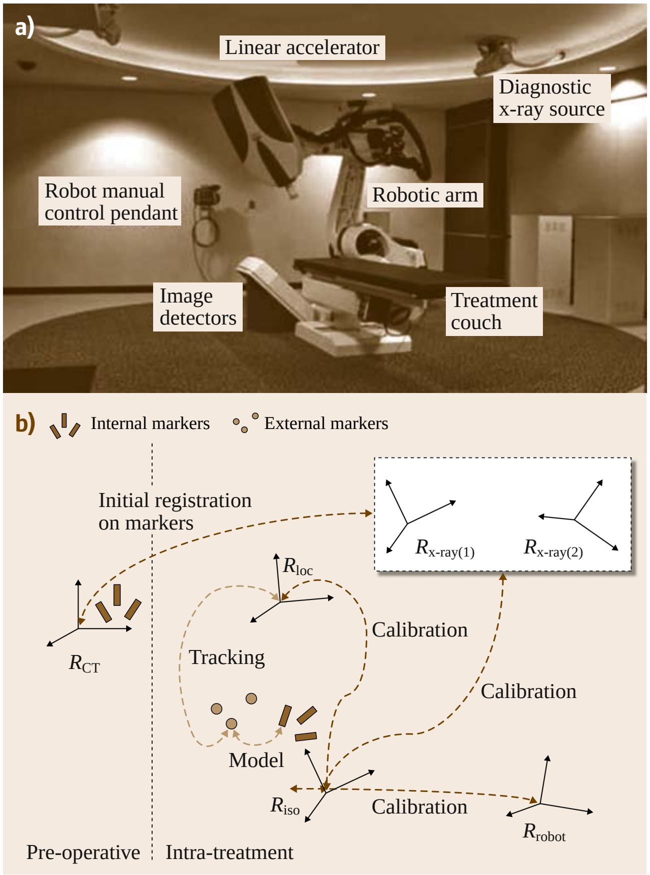

Fig. 82.4a,b The Cyberknife system: **(a)** the treatment room setup, **(b)** functional description of tracking functionalities

be fused to CT data such as MRI or positron emission tomography (PET) for planning refinement. Intraoperative x-ray imaging produced by two x-ray systems enables initial patient positioning and participates in tracking. The system is calibrated, which means that the spatial relationships between the different reference frames R_{iso}, R_{robot}, and $R_{\text{x-ray}}$ (associated, respectively, with the isocenter, robot, and x-ray devices) is determined using specific procedures and calibration objects. Such calibration is necessary to transform intratreatment imaging information into robot positions with respect to the radiation system. The transfer of planning information from R_{CT} to R_{iso} is possible due to image registration procedures described in more detail in the following sections.

In the first version of the system, dedicated to neuro applications, after initial setup, patient motion was detected and corrected before each dose delivery from a single beam. Thanks to the CT exam, two synthetic x-ray images called digitally reconstructed radiographs (DRRs) are computed. They correspond to what would be seen by the two x-rays machines in the treatment room for a perfect position/orientation of the patient with respect to planning data. Two real images are acquired just before dose delivery and automatically compared with the DRRs; this results in the computation of the patient's shift from the ideal position/orientation. For small errors, the robot position/orientation with respect to the patient is automatically corrected by combining this information with calibration data. For larger discrepancies, a replanning phase is necessary to avoid any collision during robot repositioning.

A later version of the system enables real-time tracking of organs that move with patient respiration (lung, liver, and kidney, for instance) [82.40]. As regards patient respiration during treatment, several approaches are used in conventional radiotherapy: the less accurate method consists of enlarging the targeted zone to account for tumor motion; irradiating healthy tissues is more acceptable than missing cancerous cells. This enlarged zone can be computed by combining information from two scanners acquired at the end of the exhale and inhale phases. A second approach consists of synchronizing dose delivery to a given stage of the respiratory cycle (end of inhalation, for instance) but this stage has to be reasonably repeatable and detected reliably. In a more sophisticated approach, such as that developed in the Synchrony version of Cyberknife, the system tracks the organ motion and the robot follows this motion during dose delivery in order to execute the planned treatment properly [82.41]. Since it is not possible to obtain tracking information from x-ray images – as such organs may not be visible on radiographs and continuous imaging would result in overirradiation of the patient – a localizer is introduced into the treatment room. This localizer, associated to R_{loc} and calibrated with respect to R_{iso}, is used to track passive markers placed on the patient's chest; it delivers the marker positions about 20 times per second. X-ray images can be acquired about every 10 s. Because the motion of internal organs is different from chest external motion internal radiopaque markers are implanted close to the tumor before the preoperative CT examination. The relationship between the tumor position and the internal markers is determined using the CT data; the internal markers enable initial patient setup by registration of CT data to x-ray images. The relationship between internal markers visible on x-ray images and external markers tracked by the localizer is learnt in a preliminary stage where both data are acquired during several breathing cycles. During dose delivery, between two successive x-ray acquisitions, the position of internal markers is interpolated from the position of the external markers and from the model; each new acquisition enriches the model by adding a new couple of synchronous positions of internal and external markers. Finally, the position of the tumor can be deduced from the internal markers and fed back to the robot for tracking and accurate dose delivery in spite of organ motion. The different components of the tracking function are illustrated in Fig. 82.4b. Current work deals with noninvasive alternatives to the implanted internal markers.

As can be seen in this example, a lot of hardware and software components are associated with the robot and many stages are involved in real-time determination of the robot position with respect to the patient. To provide the required accuracy for precise dose delivery, errors have to be reduced as far as possible for each of these elements; this is especially demanding. Moreover, because the robot develops very large forces and torques in the immediate vicinity of the patient, reliability and robustness are mandatory. Unfortunately, as for many other commercialized systems, due to intellectual property issues few data are available concerning detailed industrial developments and technical testing.

The Cyberknife approach supposes the ability to install a linear accelerator as end-effector of the robot; the Cyberknife robot typically carries 6 MeV accelerators which are quite compact and light compared with other radiation devices. When higher power is necessary or when radiation beams are produced by synchrotrons and/or cyclotrons – for proton therapy, for instance – the radiation source cannot be positioned and oriented by a robot. Alternative systems [82.47] have been proposed to position the patient robotically relative to the radiation beam by means of parallel robotized seats or robotized couches.

82.6 Specific Issues in Medical Robotics

As has been briefly introduced in the previous sections, medical robotics raises specific issues at the technical, clinical, and organizational levels in a very intricate way. This section discusses those issues in more detail.

Firstly this type of robot has to be used in a human environment. Because these robotic systems generally require close collaboration with a clinician, specific man–machine interface questions have to be resolved. In the case of surgery, the operator cannot interact easily with classical man–machine interfaces because he/she has to work under sterile conditions. This motivates the development of specific interfaces such as voice control or foot pedals. In the case of comanipulation, the part of the robot that is held by the clinician must be made sterile before each intervention. Because the robot is used in close proximity to human beings – at least the patient – safety issues are mandatory. Safety has to be demonstrated both at the hardware and software levels. Various approaches are possible [82.48]. The choice of specific architectures of robots or comanipulation control modes may solve part of the problem. Norms and regulations are intended to guarantee that the system is safe. However, it would certainly be interesting to develop such systems using specific design methodologies introduced in critical applications (aeronautics, nuclear plants, etc.) to really anticipate the behavior of such a complex system and avoid any misuse. This direction is still to be explored.

The clinical use of the robot also requires electromagnetic compatibility with the environment, in particular in the OR. When the robot is used in specific environments such as inside a CT or MRI imaging sensor, the robot must not disturb image acquisition or corrupt the data. This may significantly constrain design choices and selected materials: for instance in the MRI environment no ferromagnetic parts should be integrated into the robot. Sterile cleaning of the robot is also an issue. Bone-mounted robots, which come into very close contact to the patient, must be completely cleanable. This is the case, for instance, for the Praxiteles and LER-VIKY systems (Sect. 82.3.3), which are autoclavable. In the case of larger robots, their end-effector may be introduced inside sterile disposable plastic bags. However, the robot connection with the tool that is in contact with the patient has to be cleaned in a sterile way. Finally, the system and the robot must be designed such that the robotic procedure can be easily and rapidly converted into the conventional intervention, at any time, in case of problems. This may also have important design consequences.

As mentioned previously, introducing a new medical device requires demonstrating the added value over existing techniques from a clinical perspective; for instance, using the robot could enable performing less-invasive interventions, resulting in shorter stay of the patient in the hospital. In the same way, using a robot to hold the endoscope may save one assistant who can be transferred where his/her skills are used in a much better way. However, evaluating such organizational benefits obviously requires very precise cost and resource management: all necessary human or material resources participating in the intervention, from diagnosis to long-term follow-up, have to be taken into account. On a more medical level, using a robot to machine bone for prosthesis placement may result in longer lifetime of the prosthesis and/or fewer joint disjunctions (for the hip, for instance). In a similar way using a complex radiotherapy treatment delivered using a robot may allow dose escalation and may result both in better control of a tumor and fewer complications. In general, it is not easy to predict how accurate and sophisticated a robotic procedure should be to make a significant difference on the clinical level. To prove this may also be very challenging. The evaluation of clinical benefits may require long-term trials involving several centers and many patients. Those clinical trials have to be conducted in accordance with the ethical standards and regulations of the country concerned; those standards and regulations may be very strict, but they vary from country to country. Finally, added value may also be evaluated in terms of commercial advantage for a hospital that may attract more patients when high technology is used for painless, minimally invasive procedures. This added value should be significant enough to compensate for drawbacks related to the introduction of a robot such as the increase of procedure duration, which is often observed even when the learning period is finished. (See Chap. 77 for additional content on automation in hospitals and healthcare.)

Cost is obviously another issue; indeed, several of the distributed systems are quite expensive. If we consider some of the systems (for instance, Robodoc, Caspar, DaVinci, and Cyberknife) listed in Table 82.1, costs average in the range US $1 000 000–2 000 000. Aesop cost around US $100 000. Frequently a maintenance cost of 10% per year has to be added, and some of these systems generate an extra cost per intervention (for instance, about US $1000–2000 for the DaVinci system). This may be quite a heavy cost for hospitals and clinics. Moreover, depending on healthcare funding models in different countries, some of those costs may not be affordable by health insurances. The higher the investment, the more significant the added value has to be to justify the expense. More recently developed systems (smaller and simpler robots, disposable devices) are likely to propose more affordable solutions.

82.7 Systems Used in Clinical Practice

For 20 years many medical robotic systems have been developed in laboratories and evaluated to a certain extent. Evaluation is twofold: at the technical level it consists of characterizing accuracy, reliability, robustness, etc. This stage may be realized on laboratory setups using phantoms that mimic, more or less realistically, the concerned part of the body. At the clinical level, experiments with corpses or animals enable a first approach to a more realistic evaluation of clinical feasibility and performance. Finally, a study on series of patients is always necessary to fully evaluate the system and its clinical added value. Relatively few medical robots have undergone the whole evaluation process, reached the market, and gone into wide clinical use. There are indeed two major challenges: how to turn a laboratory prototype into a certified product, and how to make this product an industrial success. The reasons for this still limited diffusion of medical robotics in the clinical world certainly come from the specific constraints of medical robotics discussed above and probably from the questionable added value of the robot in a number of cases. The complexity of clinical evaluation, certification, and marketing also makes the process very long and expensive; for instance, in orthopaedics, demonstrating the advantage of robots over competing techniques may take more than 10 years since the stability and life duration of prostheses cannot be demonstrated any earlier. At the same time, to evaluate them it is necessary to install robots in hospitals, sometimes at the company's expense. Convincing a hospital to buy such expensive devices before any medical evidence of their added value is available is particularly challenging.

Table 82.1 attempts to list as largely as possible the industrial systems that are, or have been, significantly clinically used in routine and emerging products; this table is intended to give a flavor of the clinical spread of the technique. Numbers of systems are estimates established in early 2008. As can be seen several systems are no longer distributed: this deserves further comments. Surgiscope and MKM, which are both *surgical microscope holders*, probably faced a limited *added value versus cost* ratio. As regards Robodoc, this system had not yet demonstrated a clinical benefit when misuse of the robot resulted in many clinical complications and legal cases in Germany; this ended up with the removal of the robot from the US and European markets. Caspar, which offered functions very similar to those of Robodoc, probably suffered from the same unproven added value issue and from the failure of Robodoc. Aesop and Zeus are no longer distributed due to intellectual property conflicts. Aesop was, however, very successful in clinics and could certainly be considered as an industrial success.

The success of DaVinci is probably due to its ability to offer intrabody DOFs for endoscopic surgery; laparoscopic radical prostatectomy is one of the main clinical vectors of the large dissemination of the DaVinci system. As regards Cyberknife, the ability to perform complex dose distributions with tens of small radiation beams and the capacity to radiate the tumor accurately during patient respiration are probably the keys to its success. Moreover, conventional radiation apparatus are expensive devices and cost issues may be less critical in the case of radiation therapy than for surgery.

Table 82.1 also shows that emerging systems are often based on quite different design philosophy: small dedicated systems with more interactive control schemes. As can be seen, favorite applications are in endoscopy and knee arthroplasty, where the market is large (6 000 000 laparoscopic surgeries per year worldwide, and 600 000 knee prostheses per year worldwide).

Many other systems are somewhere in between the academic and industrial worlds and are not included in this table. Several of those forthcoming devices concern the introduction of needles into the body (for biopsies, punctures, brachytherapy, etc.).

82.8 Conclusions and Emerging Trends

In this chapter, we have introduced the main motivations for computer-assisted medical interventions and presented the place of medical robots in this general paradigm. Different generations of robots have been proposed and evaluated worldwide, ranging from systems inspired from industrial automation to more specific clinical robots. In parallel to those evolutions in terms of robot architecture and application areas, we have shown that the control modes also evolved in different directions: giving a larger place to the operator through real cooperation or closing the control loop with real-time imaging data for tracking mobile and deformable targets. The future is probably in the merging of such type of controls; for instance, the robot might handle synchronization with a moving organ while the operator would control the fine motions with respect to the stabilized target.

As regards industrial products resulting from this domain, the evolution has been very similar. The future will tell if those new design choices will result in a much larger spread of medical robots. Reference [82.49] reports 39 000 service robots for professional use installed worldwide up to the end of 2006, among which 9% (about 3500 devices) would be medical robots. However, this report does not tell precisely what is included in this category (for example, integration of haptic devices, integration of mechanical localizers or others). From the numbers mentioned in Table 82.1, our estimate of installed robots in 2008 would be closer to 2500, which is probably less than half the number of installed navigation workstations. Increasing this ratio requires careful selection of applications with significant added value and the development of user-friendly cost-effective systems. Intrabody highly integrated mechatronic devices potentially open the range of applications in a dramatic way. This domain has still to be largely explored.

82.9 Medical Glossary

- Aneurysm: a local hernia on a blood vessel potentially resulting in vessel rupture and internal haemorrhage
- Autoclavable: being cleanable in the autoclave (pressured vapor sterilization with temperatures greater than 100 °C)

- Arthroplasty: plastic surgery of the joints involved, for instance, in joint replacement (e.g., hip, knee)
- Biopsy: the action of taking samples of a tissue with a needle for further analysis
- Brachytherapy: the introduction of radioactive seeds into an organ for tumor destruction
- Catheter: a flexible tube introduced into the body, typically blood vessels, for instance, to inject drugs or to place dilatation devices. Generally, the end of the catheter can be slightly curved by the physician from the outside of the body
- Colonoscopy: endoscopic examination of the colon
- Computed tomography (CT): 3-D imaging from x-ray acquisition, enabling good visualization of bony structures and air cavities
- Digitally reconstructed radiograph (DRR): a synthetic x-ray projection image computed from a CT volume being given the position of a virtual source and virtual image plane
- Endoscopic surgery: surgery involving a minimal access to the body through natural cavities or incisions and visualization of the internal organs using rigid or flexible optical sensors (the endoscope)
- EC marking: the certification from the European Community necessary for marketing a products of any type in the Economic European Community; it insures that the product complies with the European regulations in terms of safety, health, environment, etc.
- FDA: Food and Drug Administration; the US administration in charge of controlling the safety and efficacy of health-related products (http://www.fda.gov)
- Interventional radiology: a category of therapeutic or diagnostic procedures executed under imaging control
- Magnetic resonance imaging (MRI): 3-D imaging from magnetic resonance of hydrogen protons in the body, enabling detailed visualization of soft tissues
- Neurosurgery: brain or spine surgery
- Operating room (OR): also called operating theater
- Orthopaedics: a surgical specialty dealing with skeleton bones and joints
- Positron emission tomography (PET): a functional imaging modality in which a radioactive marker is associated to a metabolically active molecule and injected into the body of the patient; the metabolic activity is traceable thanks to the radioactive marker and can be reconstructed in 3-D thanks to tomography techniques similar to the one used for CT
- Puncture: the action of inserting a linear tool (a needle or an electrode for instance) into the body
- Preoperative, intraoperative, postoperative: before, during, after the intervention
- Prostatectomy: surgical removal of the prostate in case of cancer; laparoscopic prostatectomy is the minimally invasive version of this surgery
- Radiopaque: visible on x-ray images
- Radiotherapy: the destruction of pathologic tissues (mostly tumors) by ionizing particles
- Stereotactic neurosurgery: a minimally invasive access to the brain requiring very accurate localization of intracranial structures
- Stereotactic frame: a mechanical device for perfect immobilization of a patient's skull, also used for transferring the surgical plan and for guiding the surgical tool
- Ultrasonic examination: an imaging modality (2-D or 3-D) based on the propagation of ultrasound in the body; it visualizes tissue interfaces.

Home, Of

Part I Home, Office, and Enterprise Automation

Home, Office, and Enterprise Automation. Part I This part is about functional automation areas at home, in the office, and in general enterprises, including multi-enterprise networks. Common to these areas is the power of automation appliances, such as home and office appliances, and of Internetworking, such as collaborative decision support and scientific exploration, collaborative work, and e-Activities, from service to business, banking to home-office, laboratories, schools, government and tele-work. Chapters also cover the automation theories, techniques and practice, design, operation, challenges and emerging trends in education and learning, banking, commerce. General automation principles and functions include decision support, collaboration, integration, planning, services for unique needs such as disabilities, and business process automation. An important dimension of the material compiled for this part is that it is useful for all other functional areas of automation, for instance, office and school automation, interoperability, client relations management, enterprise resource planning, and collaborative decision support (all subjects of this part) are directly applicable to industrial, infrastructure, agriculture, medical, transportation, service, and other domains of automation.

83. Automation in Home Appliances

T. Joseph Lui

Home appliances, by their very nature, represent realizations of the principles of automation. Home appliances exist for the purpose of automating otherwise manual processes in the home. The operation of home appliances has been refined over the years, though the machine function has remained essentially the same. Advancements in the areas of microprocessor-based controls, sensors, displays, and interconnectivity, however, are enabling a new generation of appliances with advanced automation capabilities. Smart refrigerators, smart cooking appliances, and smart cleaning appliances are already appearing on the market. Along with these appliances we observe the viability of advanced applications in home automation. Software-based controls, appliance area networks (AANs), and display devices capable of creating a rich user experience are enabling advances in refrigeration automation, cooking integration automation, automated home utility management, automated fault and performance monitoring, and more. In this chapter we explore the enabling technologies and applications of advanced home appliance automation.

Convenience – in the form of home chore automation – has always been the primary justification for a consumer to purchase a home appliance. Major home activities including refrigeration, cooking, and cleaning have enjoyed substantial levels of automation for many years. In this chapter, we explore the history of home chore automation, enabling technologies for advanced automation, and several applications thereof. We will not address heating, ventilation and air-conditionning (HVAC), lighting, entertainment, or security systems. Interested readers can refer to Chaps. 62 and 71 for treatment of these topics. Here, we focus specifically on major appliances, namely, refrigerators, dish washers, cook tops and ovens, clothes washers and dryers, and microwave ovens. We do not address smaller appliances such as food processors.

83.1 Background and Theory

83.1.1 History

Home appliances, by their very nature, automate an otherwise manual process. The clothes washer automates the manual process of fabric care. The food processor automates portions of the manual processes of food preparation. The list goes on. So, in a sense, the home was the first place in which automation received mass-market appeal. The automatic clothes washing machine was introduced in the USA commercially in 1911 and was a common feature of US homes by the close of the 1920s. Today, 80% of US homes have a clothes washer [83.1]. Moreover, though the microwave oven was only introduced in 1967, the convenience provided has resulted in around 85% of households having the appliance today. 1967 is the year of introduction of the first commercially viable countertop microwave oven: the *Radarange* from Raytheon/Amana. The first microwave oven of any kind was introduced in 1947, also by Raytheon [83.2].

Home appliances are on a long evolution path in which they have been improved aesthetically, refined operationally, and cost-reduced. However, the degree of automation of the fundamental processes has not changed substantially: a refrigerator still essentially keeps food cold; a water heater still basically keeps water hot. Typically, the quantum leaps in home appliance automation have not occurred within existing appliances, but with the introduction of new appliances. Examples include the microwave oven in 1967 and the trash compactor in 1969. However, opportunities for increased automation of the processes performed by existing appliances do exist and are under development.

Advanced automation opportunities for home appliances appear on two fronts: convenience and precision. Existing processes can be made more convenient for the user, for example, by reducing the amount of user input and intervention required by the process. Processes can be made more precise and, in particular, more efficient by transferring some decision-making responsibilities from the user to the appliance itself.

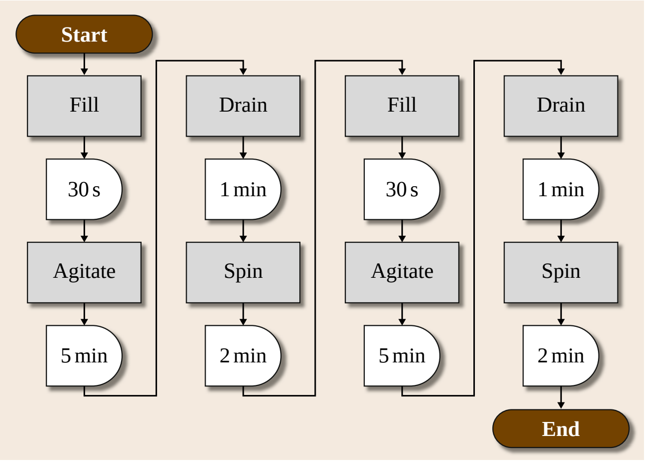

Fig. 83.1 Simple clothes washer algorithm

83.1.2 Enabling Technologies

Microprocessor Controls

The fundamental enabler for advanced home appliance automation has been the introduction of microprocessor-based control systems and associated software. In the past, electromechanical control systems have made dramatically increased automation either infeasible or impractical. However, virtually all modern major appliances – spanning refrigeration, fabric care, and cooking – are now equipped with a programmable microprocessor, thus setting the stage for quantum leaps in automation.

Sensors

Microprocessors ostensibly can implement their processes without environmental inputs; for example, a clothes washer could operate based on the simple algorithm presented in Fig. 83.1.

However, advanced automation and, in particular, increased efficiency are dependent on retrieval of information from the process environment. Thus, another key technological enabler is environmental sensors. Examples of important sensors include:

- Temperature sensors
- Flow meters
- Optical cameras
- Infrared sensors
- Chemical sensors
- Radiofrequency identification (RFID) receivers.

Temperature sensors give the microprocessor access to, for example, the temperature of inflowing water, ambient or internal air, and food in the case of refrigeration and cooking appliances. Flow meters are employed primarily to provide data on water volumes, which can be crucial to achieving a desired water temperature. Optical cameras provide inputs to, for example, food doneness determination algorithms. Infrared sensors provide noninvasive means to evaluate temperature, while chemical sensors provide key data for evaluating things such as detergent concentrations.

The sensors introduced above generally serve to evaluate the physical characteristics of some element of the process being executed, or the thing on which the process is operating (food, clothing, etc.). However, an RFID receiver provides access to stored data about the item being processed which is not otherwise accessible – at least not cheaply and conveniently. For example, RFID tags embedded in clothing could contain informa-

Spin
Read water outflow & detergent concentration
Water outflow, detergent concentration OK?
End

Fig. 83.2 More advanced clothes washer algorithm

tion on the composition and care of the garment, such as parameters dealing with appropriate water temperature, detergent type, and washing cycle. RFIDs contained in prepared food packaging could contain information on composition and instructions for preparation, such as cooking temperature and time. Thus, RFIDs provide access to a rich cache of information which can be leveraged for automation. The term *RFID* in this context is not intended to pertain to any specific radio technology or technical standard, but to the general concept of wireless, short-range, passive information retrieval.

Now, returning to the algorithm presented above, given a sufficiently capable array of sensors, we might be able to automate the process as shown in Fig. 83.2. This revised algorithm is critically dependent on the availability of sensors. Modern home appliances are being equipped with ever more sensors to enable cycle optimization and efficiency, as well as process automation.

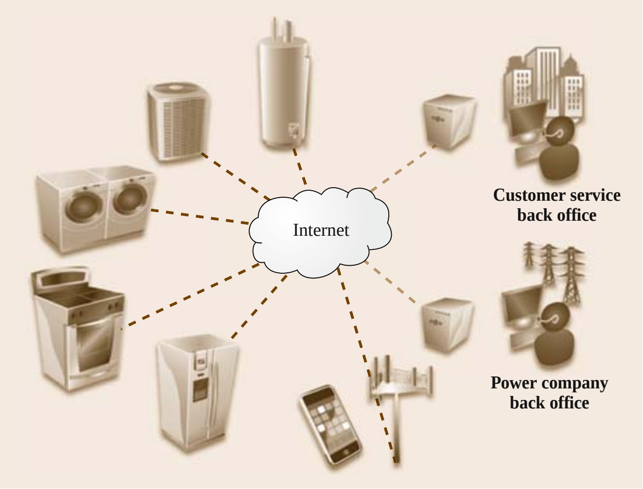

Fig. 83.3 Remote appliance communication

Connectivity

In addition to collecting and processing information within the home appliance, automation opportunities are further expanded if the home appliance is able to communicate information externally. It can be advantageous to exchange information locally with other appliances, or remotely with other entities such as the user, the appliance vendor, or a third party such as a utility (Fig. 83.3).

These appliance area networks (AANs) can be realized in any of a number of topologies, such as star, mesh, and ring (Fig. 83.4).

In order to communicate with entities outside the AAN, though, an Internet gateway is often required. The AAN's Internet gateway could be something as simple as a broadband modem, or it could be something more intelligent, for example, in the case that the appliances and/or the networking technology do not natively support a full suite of internet protocols such as transmission control protocol/Internet protocol (TCP/IP), dynamic host configuration protocol (DHCP), and domain name system (DNS).

AANs can utilize any number of communication protocols including IEEE 802.3 Ethernet, IEEE 802.11 wireless local-area network (LAN), IEEE 802.15.4 low-rate wireless personal area network (PAN), and a multitude of public cellular networking technologies.

Once home appliances are networked together and connected to the Internet, boundless opportunities for automation exist. Some of these include:

- Automatic distribution of information amongst the appliances, for example, time of day
- Automatic coordination and optimization of electric power, water, and natura-gas usage
- Automatic status reporting and remote appliance control
- Automatic performance analysis and reporting
- Automatic fault detection and reporting.

At the time of this writing, home appliance Internet connectivity and some of the applications given above are becoming available commercially.

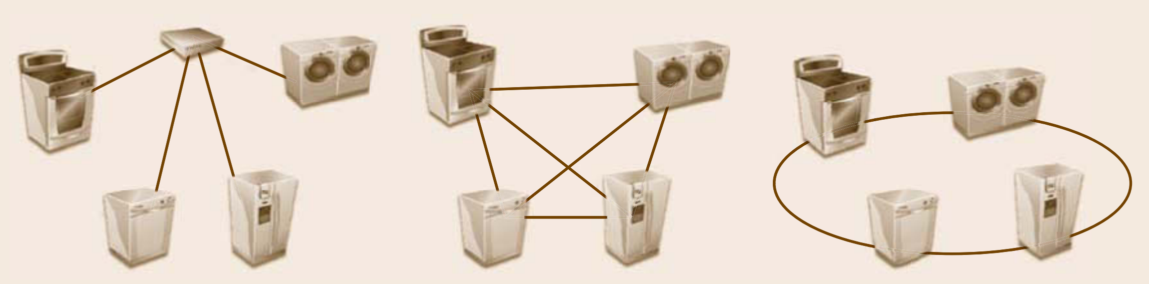

Fig. 83.4 AAN topologies

83.2 Application Examples, Guidelines, and Techniques

83.2.1 Refrigeration

It has been stated previously that the basic function of the most widely used home appliance – the refrigerator – has not changed significantly since its inception. There are, however, opportunities to automate the fridge's function significantly. The penultimate in refrigeration – the *smart* fridge – would possess at least:

Table 83.1 Smart refrigerator food inventory

Type	Subtype	Instance	Inventory date	Expiry date	Capacity	Fill level
Milk	2%	1	23-Apr	10-May	4 L	30%
Milk	2%	2	01-May	18-May	4 L	100%
Olives	Green	1	23-Apr	06-Dec	200 g	100%
Beer	Duff	1	23-Apr	N/A	6	17%
Carrots	N/A	1	23-Apr	N/A	0.5 kg	80%
...	...	...	...	...	...	...

- Automatic food inventory
- Automatic quality management.

In the basic implementation of the smart fridge concept, the type and quantity of refrigerated food would be stored in a database by the refrigerator. As items are placed in the fridge, an identifier – such as an RFID tag – is read. Similar functionality could be implemented via universal product code (UPC) symbol instead of RFID, but this would require some user intervention (the scanning of the symbol) and would this represent a semiautomatic process. The tag indicates the food type, the product brand name, the container size or weight, the use-by date, and any other information relevant to the inventory process. To this the fridge adds each item's purchase date, physical location, and other information (Table 83.1). As food is consumed, the relevant database entry is updated; for example, a half-gallon container of milk weighing 900 g is determined to be just under half full.

Several conditions trigger the ordering of food. If the food container is not returned to the fridge within a certain period of time, then the food is presumed to be fully consumed and the smart fridge flags the item for replacement. Similarly, if the container is returned to the fridge, but the fridge determines that the con-

Food item returned to fridge?
Yes
No
Add food item to shopping list
End

Fig. 83.5 Smart refrigerator inventory maintenance

tainer's contents have reached a critically low level, then the item is also flagged for replacement (Fig. 83.5). Further, if the item is nearing its use-by date, then the item is marked for replacement.

Either automatically or pursuant to a demand by the user, a shopping list can be generated. Using Internet connectivity, the list can be sent directly to an online grocer for delivery, or to a bricks-and-mortar grocer for preparation and eventual collection by the user, or to the user's computer or mobile phone. Alternatively, the list can be sent over the AAN to a printer and hand-carried by the user to the market, or simply displayed on the fridge's own video display device (Fig. 83.6).

The smart fridge concept further is conducive to maximizing food freshness and safety. Detailed knowledge of the fridge contents permits optimization of temperature and humidity so as to extend food freshness. And since the smart fridge has retained the use-by date for each item in its database, any food nearing its end-of-life can result in safety alerts to the user and automatic reordering or addition to the shopping list.

Advanced implementations of the smart fridge concept include recipe cognizance. In one realization, digital recipes – utilizing extensible markup language (XML) or an appropriate means to identify information elements within a recipe – are downloaded to the fridge over the Internet/AAN, with the fridge alerting the user as to which ingredients are lacking, and ordering them (or adding them to the shopping list) as necessary. In another realization of recipe cognizance, the smart fridge alerts the user as to which recipes can be prepared with the ingredients on hand by searching the Internet for digital recipes which are matches to the fridge inventory.

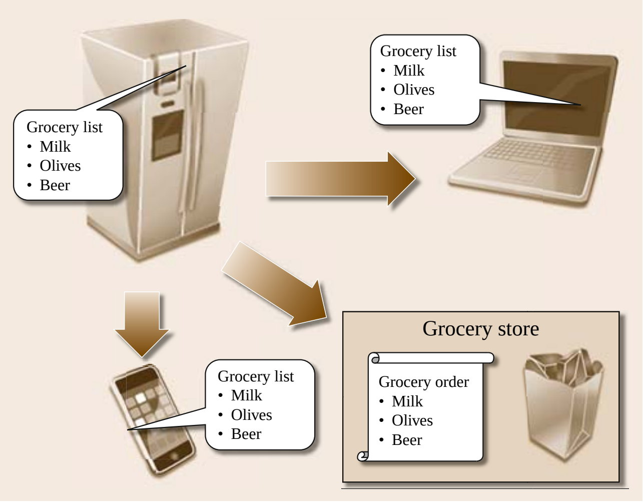

Fig. 83.6 Shopping list generation and notification

Clearly, the smart fridge is dependent on all of the enabling technologies described previously: a comprehensive array of sensors, microprocessor control, and connectivity.

83.2.2 Cooking

Cooking is, by its very nature, a labor-intensive process. However, there are several opportunities for further automation of the processes performed by each of the major cooking appliances, namely, the cook top (stove), microwave oven, and convection oven. Some possibilities are as follows.

Often, the temperature of convection ovens and cook tops is not regulated, but controlled indirectly. Rather than controlling the temperature, the appliance controls the amount of energy dissipated. The vessels used for cooking in convection ovens – and on cook tops in particular – while not part of the appliance per se, are critical components in the cooking process. Given the nature of temperature regulation, the cooking vessel is not integrated into the appliance's temperature regulation mechanism. Thus, as ingredients are added to the cooking vessel, temperatures fluctuate. With appropriate sensors, vessel temperature can be stabilized, with heat being added as sudden drops in temperature are detected, thus automating what would otherwise be the manual process of raising and lowering the energy consumption rate.

For all cooking appliances, automated doneness detection is possible. Optical sensors and internal temperature probes can be used to cook precisely to the desired doneness; for example, most meats are cooked to a desired internal temperature, depending on personal preferences for doneness. Temperature sensors can be used to cook precisely to this temperature, without over- or undershooting, with the appliance subsequently keeping the meat warm without continuing to cook it. (Note that, while temperature probes are often available from third parties, they are strictly external and not integrated with the cooking appliance's temperature control logic.)

Further, a sufficiently rich portfolio of probes enables more refined cooking cycles; for example, traditionally, we might set a convection oven to 232 °C for 10 min, then turn the temperature down to 163 °C for 2 h. A *smart* oven could be programmed to first sear, then cook to an internal temperature of 60 °C, with the appliance itself making all necessary decisions about time and temperature, thus automating the process.

In a still more advanced realization of cooking automation, the cooking appliance would be provided with detailed cooking instructions by the food itself. The food's packaging – a box or wrapper – could be equipped with an RFID tag which would be read by the cooking appliance, either as it is placed into the appliance or when it is passed near a sensor manually. This approach is clearly most feasible in the context of prepared foods. The RFID tag would contain details of the nature of the food (e.g., its type and weight), cooking time, and cooking temperature. The only required user intervention would be selecting the desired doneness, if applicable, and pressing *start*, substantially automating the process. When integrated with temperature probes and sensors, the cooking appliance could automate the entire process, from defrosting to cooking, simply taking the desired meal time as an input.

Extending the concept of a digital recipe to cooking, the power of the AAN could be leveraged to coordinate the functions of the cooking and refrigeration appliances and substantially automate food preparation from end-to-end: The smart fridge would manage the ordering and inventory of ingredients, while the smart cooking appliances would manage the cooking based on XML-encoded instructions (time and temperature) in the digital recipe or a similar information classification protocol (Fig. 83.7).

83.2.3 Cleaning

Cleaning appliances – clothes washers, clothes dryers, and dish washers – again offer a substantial degree of process automation by their very nature. However, further levels of automation are possible. Some examples are as follows.

Washing appliances – clothes and dish washers – are optimized by their users according to the nature of the task at hand. The number of cycles offered by each machine is limited, and users sometimes utilize only one or two of the available cycles. Thus, there exists the opportunity to automate the decision-making process further. With an appropriate array of sensors – such that the fabric/dish type, volume, and soil level can be assessed – the washer can automatically optimize its cycle. Among the variables which can be adjusted are the wash, rinse, spin, etc. durations, the nature of the chemistry (such as the detergent type and volume), and optimal water temperature and volume.

Fig. 83.7 Semiautomated food preparation

In an even more advanced implementation, clothing and dishes would be equipped with RFID tags which would inform the appliance as to the nature of the item as well as specific care instructions. The cleaning appliance could then determine the optimum washing/drying cycle based on all the contents loaded into the machine, perhaps suggesting, for example, that certain items should not be washed together, or should not be machine washed (or dried) at all (Fig. 83.8).

It is easily observable that water-consuming appliances such as clothes washers and dish washers can cause a substantial drop in household water pressure during their operation. They can also consume a substantial portion of the household hot water reserve. The power of the AAN can be leveraged automatically to coordinate the operation of water-intensive processes; for example, the clothes and dish washers can communicate over the AAN to ensure that they do not both operate at the same time, and both devices can communicate with the water heater to ensure a sufficient reserve for other water-intensive activities in the home (Fig. 83.9). Both appliances further could be configured to avoid operation during bathing times.

83.2.4 General Appliance Automation

Thus far we have examined the automation of the specific processes performed by individual home appliances. We now examine automation as it pertains to home appliances in general. Microprocessor control, sensor arrays, and connectivity enable a number of generic automation functions in any so-equipped home appliance. Some possibilities include:

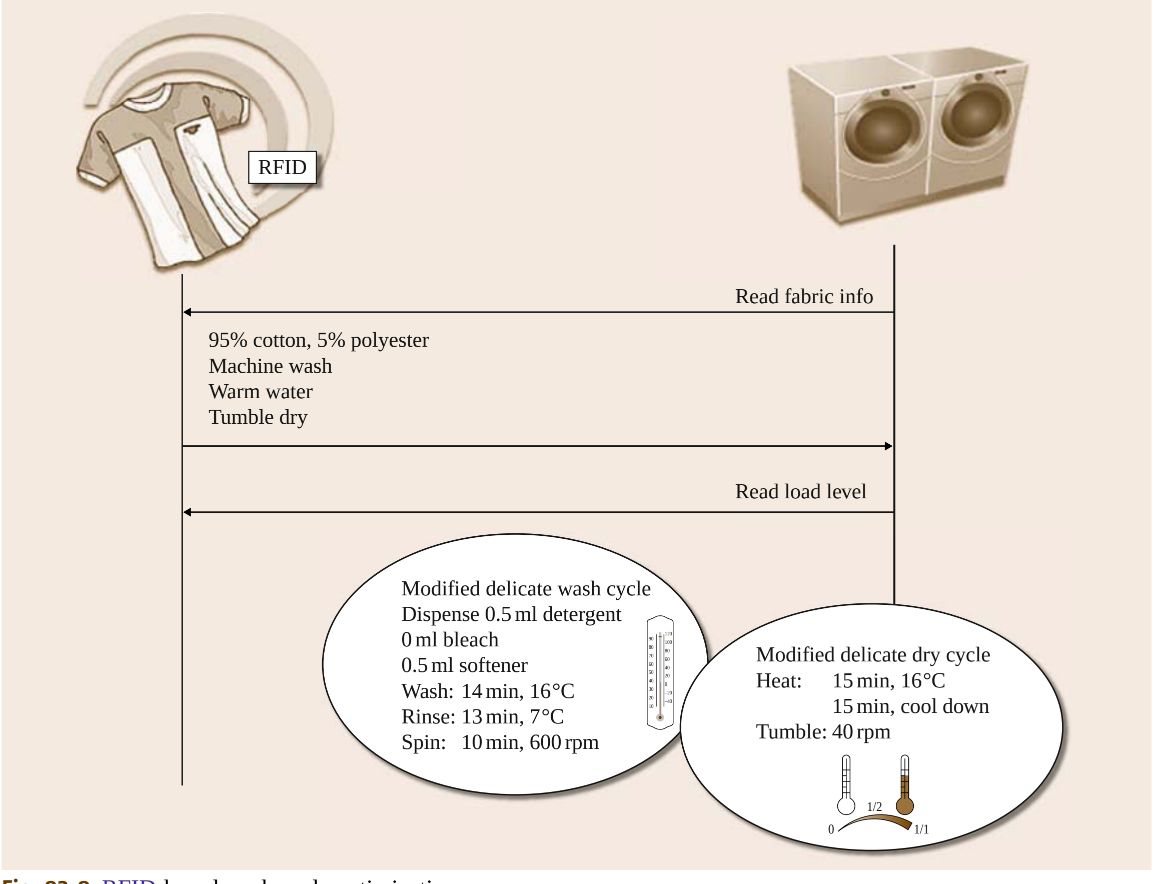

Fig. 83.8 RFID-based wash cycle optimization

- Performance monitoring
- Fault monitoring
- Software maintenance
- Consumables monitoring.

Performance Monitoring

Traditionally, poor appliance performance is not detected and acted upon until it degrades to a catastrophically-low level; for example, a refrigerator evaporator fan becomes clogged with debris and the fridge fails to cool effectively and begins to consume inordinate amounts of energy. As performance continues to degrade, the fridge is unable to maintain a sufficiently low temperature and food spoils, resulting in a risk to the user's health. Usually only when this near-fault condition occurs is the user alerted to the problem. However, advanced automation techniques permit home appliances to monitor various internal performance metrics continuously. In our example, this might include:

- The electric current drawn
- The condenser fan *on* time
- Time during which the cooling chamber exceeds the desired temperature.

These metrics could be compared against their long-term average values, or against some factory-programmed limits. If performance, as determined by these metrics, degrades below the desired level, the user or the appliance service center is automatically alerted – by the appliance – to the need for maintenance (Fig. 83.10), thus avoiding a catastrophic outage and food spoilage.

Fault Monitoring

Similarly, appliance faults which are not preceded by gradually degrading performance can be acted upon automatically. Appliances can execute internal diagnostic testing periodically and can detect when subsystems

fail. This information can both be shown on the appliance's video display and be reported to the appliance service center. Armed with exact knowledge of the fault, the responding technician can be dispatched with all necessary tools and parts, minimizing the time to repair and the need for a follow-up visit to the user premises.

Critically, large volumes of fault and performance data – gathered from an appliance vendor's installed base – can be aggregated and analyzed to spot trends. Subcomponents which have unusually high fault rates can be swapped in the manufacturing process to reduce the incidence of the fault in future appliances (Table 83.2). Similarly, appliances showing trends in a certain mode of performance degradation can be redesigned to minimize the likelihood of occurrence in future units.

Software Maintenance

Once home appliances are functional Internet nodes, it becomes possible to automate appliance software maintenance. Just as a home personal computer (PC)'s operating system and application software are updatable automatically via the Internet, so can an appliance's software be updated. As software bugs are discovered, new loads containing the bug-fix can be pushed out to the connected appliances, eliminated the need for a service call, the need to disassemble the appliance, or even the need to connect tools – such as a PC – to the appliance. Beyond bug-fixes, this technique can be used to deploy new software-based functionality, such as new or optimized machine cycles. This is a particularly powerful capability when used in conjunction with the aforementioned large-scale performance data analysis, which might indicate that certain software parameters – such as performance thresholds – need to be tweaked.

Consumables Monitoring

Some home appliances utilize *consumable* items – items which have a limited useful life and must be replaced periodically. Examples include filters and additive or detergent cartridges. When an appliance is

under microprocessor control, the remaining life of consumables can be monitored precisely. When this metric falls below a predetermined threshold, the connectivity capability can be used to reorder the consumable automatically, thus eliminating the possibility of appliance downtime or degraded performance.

83.2.5 Household Energy Management

For a number of reasons, household energy usage – primarily electric power usage – has been brought to the forefront of the energy debate. Concerns over climate change, energy supply stability, and national energy independence have refocused government and public utilities on the issue.

A particular concern of electric utilities is transient peaks in demand which exceed the utility's ability to produce power. In such situations, the utility is forced to purchase energy on the open market from a third-party supplier. Since such suppliers know that electric power in such *overload* conditions is extremely valuable to the utility, they charge relatively high prices for the electricity, negatively impacting the utility's margins, in some cases to the extent that the utility loses money, after having sold the electric power for less than it cost to acquire it. In order to minimize their loss, utilities some-

Table 83.2 Trending using aggregated performance data

Type	Subtype	Model	Revision	Units in field	Fault code	Fault instances
Refrigerator	Side-by-side	K123	2	67 839	1	0
Refrigerator	Side-by-side	K123	2	67 839	2	0
Refrigerator	Side-by-side	K123	2	67 839	3	42
Refrigerator	Side-by-side	K123	2	67 839	4	690
Refrigerator	Side-by-side	K123	2	67 839	5	0
...	...	...	...	...	...	...

times must cut their supply of power. In order to *spread the pain*, this is done for brief periods within a number of geographic regions, producing the infamous *roving brownouts*.

In other industries, if a supplier runs out of capacity, it simply builds or otherwise procures additional supply capacity. In the case of a manufacturer of goods, a new factory might be constructed. However, electric power generation facilities are both expensive to build and sensitive politically. So increasing supply is difficult and sometimes infeasible. In order to address the electric power supply–demand problem, utilities have taken a demand-side approach. This approach entails direct control of power consumption by the electrical devices – including appliances – in the home, as well as in load-based, real-time pricing of electricity. Thus we introduce the concept of automated electric power usage in the home.

Direct Load Control

Direct load control (DLC) refers to the ability of the electric power utility to reduce the amount of power consumed by electrical equipment in the home by communicating directly with the equipment, without the need for resident intervention [83.3]. Examples of home electrics which are key to the DLC strategy include HVAC systems, electric water heaters, and major appliances.

With DLC, as the utility approaches its capacity limit (Fig. 83.11), it sends signals to the home electrics which indicate the need to conserve power; for example, the HVAC system can be requested to operated at a higher (in summertime) or lower (in wintertime) temperature. Likewise, the water heater can be requested to switch off temporarily, resulting in power savings with a slight reduction in water temperature. Electrical appliances – which sometimes have complex operating cycles – can be requested to operate in high-efficiency mode, or to delay starting until the power demand has subsided.

Many architectures exist for realizing DLC-based automated home energy usage control. In one implementation, the electric utility operates a server which monitors instantaneous power demand. As demand continues to rise toward the utility's peak capacity, the server sends signals to *smart* power meters in participating homes, which in turn send signals – perhaps wirelessly – to the subtending appliances, indicating the need to conserve power (Fig. 83.12).

If the number of participating households is large, and if the aggregated power savings are sufficient, then the utility can avoid going to the open market to procure power and the associated possibility of a brownout. As demand begins to wane, the utility's server signals the smart power meters with a signal indicating that power consumption can return to normal. Thus, home power demand control is automated.

DLC is most applicable in markets where retail pricing is regulated, i. e., real-time pricing is not possible. Consumers are offered incentives to participate in DLC programs in the form of rebates from the electric utility.

Real-Time Pricing

Real-time pricing refers to the electric utility's ability to vary pricing for electric power over relatively short periods of time, for example, on a per-hour basis [83.4].

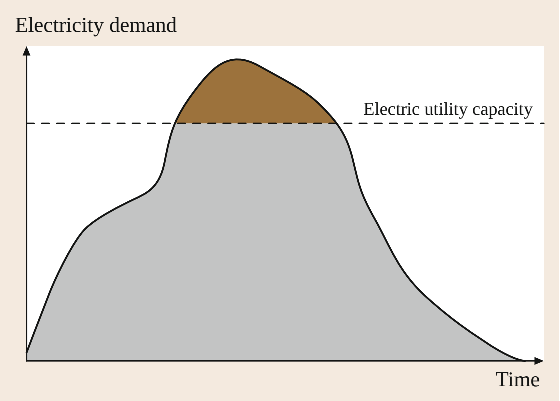

Fig. 83.11 Hypothetical electricity demand versus electric utility capacity

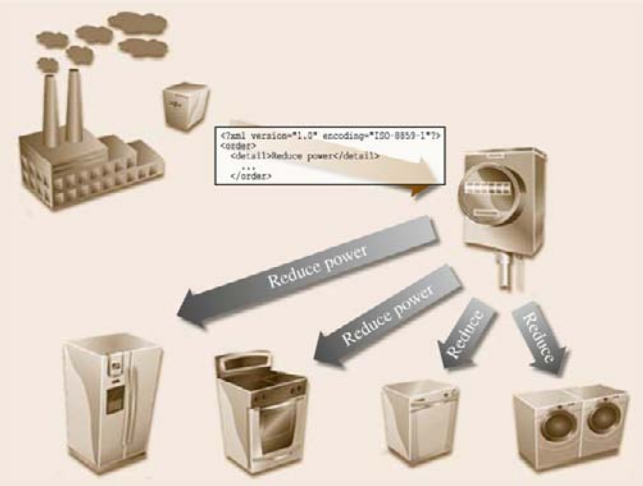

```

  <detail>Reduce power</detail>
    ...
  </order>
```

Fig. 83.12 Direct load control using smart power meters

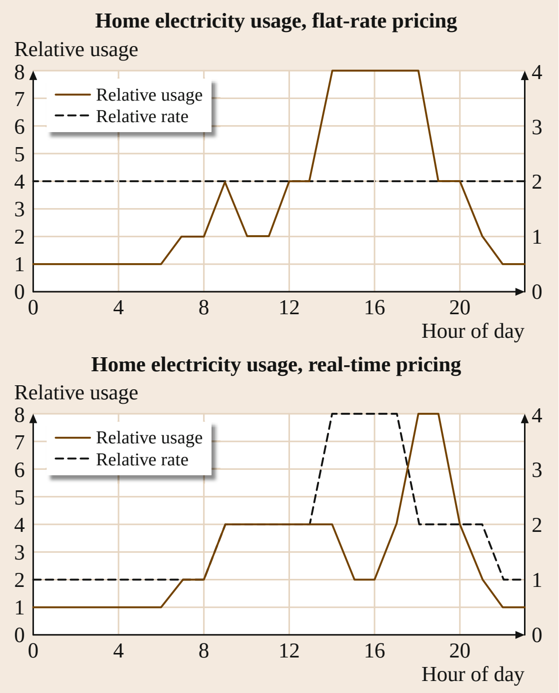

Fig. 83.13 Home electricity usage: flat-rate versus real-time pricing

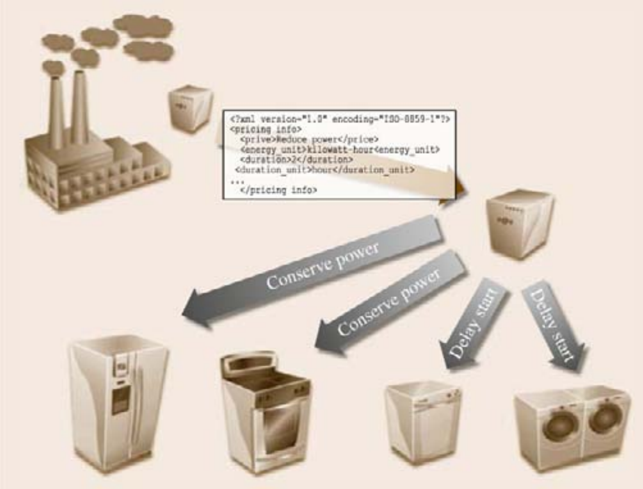
Real-time pricing can be used – among other things – to disincentivize power consumers from using power during periods of peak demand. This reduces the probability that the utility's own capacity will be exceeded, and minimizes the likelihood that the utility has to purchase additional power on the open market.



```
<?xml version="1.0" encoding="ISO-8859-1"?>
<pricing info>
  <prive>Reduce power</price>
  <energy_unit>kilowatt-hour<energy_unit>
  <duration>2</duration>
 <duration_unit>hour</duration_unit>
...
  </pricing info>
```

Fig. 83.14 Real-time pricing using appliance control node

When real-time pricing information is relayed to consumers, they make decisions about how to use their home electrics so as to keep their electric bill within their spending limits. So, for example, during peak hours in summertime, residents can choose to set thermostats to a higher temperature in the mid-afternoon, when energy prices are highest. Likewise, certain household activities – such as laundry and dish washing – can be deferred until pricing is more amenable (Fig. 83.13). With enough participating households, the aggregated power demand on the utility is eased to the point that it does not have to purchase additional power from a third party.

We have described a mechanism by which electric utilities can *automate* demand control by manipulating the retail price of power. However, further power consumption automation opportunities exist on the consumer side. If the pricing information is relayed directly to appliances – for example, via a smart meter – then compatible appliances can automatically adjust their cycles so as to minimize the net energy cost; for example, the clothes washer, after having received a *start* signal from the user, could delay starting its cycle until energy prices are more favorable.

Alternatively, if pricing information is relayed to a hypothetical appliance control node located in the home, the control node can schedule appliance (and HVAC, water heater, etc.) operation so as to meet consumer-configured criteria regarding comfort, convenience, and cost (Fig. 83.14).

For example, the user could decide that he wants to:

1. Minimize cost during weekdays
2. Balance cost with comfort and convenience during weeknights
3. Maximize comfort and convenience on weekends.

The control node would then configure and schedule tasks accordingly. This could mean, for example, switching off the air conditioning during weekdays, raising the temperature slightly on weeknights, and operating it normally all weekend.

A more sophisticated energy control node algorithm might look something like that shown in Table 83.3.

Thus the user can achieve the optimal balance of electric power cost and comfort and convenience in an automated way.

Table 83.3 Appliance energy control node algorithm

	A/C	Water heater	Clothes washer	Clothes dryer	Dish washer	Fridge
Weekdays high price	Temperature: – 6.67 °C	Temperature: – 6.67 °C	Deferred operation	Deferred operation	Deferred operation	High efficiency
Weekdays low price	Normal	Normal	High efficiency	High efficiency	High efficiency	Normal
Weekends high price	Temperature: – 16.1 °C	Temperature: – 12.2 °C	High efficiency	High efficiency	Deferred	Normal
Weekends low price	Normal	Normal	Normal	Normal	Normal	Normal

83.3 Emerging Trends and Open Challenges

83.3.1 Trends

Display Devices

Advancements in home appliance automation are driving – and are enabled by – advancements in display devices. More and more appliances are available with advanced light-emitting diode (LED), monochrome liquid-crystal display (LCD), and full-color LCD display devices (Fig. 83.15). These user interfaces (UIs) facilitate the richer user experience required for advanced status and control (input/output, I/O) functions, such as those required by advanced automation techniques.

For example, with either the DLC or real-time pricing modes of energy management, the appliance user must be informed of in-process energy management activities. In the case of DLC, the user must know when the utility is actively managing the appliance. For real-time pricing, the user needs to be apprised of the current price of power. In either case, the user must have the ability to control the appliance's behavior. A user might want to override DLC or the real-time pricing program if some process, e.g., laundry, needs to be performed immediately due to some immanent need. All of these functions required the rich I/O facilities which advanced display devices provide.

Interconnectivity

Most advanced appliance automation techniques require remote transmission of information to, or remote retrieval of information from, the appliance. This implies that appliances must interconnected – to each other, and most importantly to the Internet. Household energy management, remote performance analysis and fault detection, and remote software maintenance are all critically dependent on interconnectivity. Thus, in-

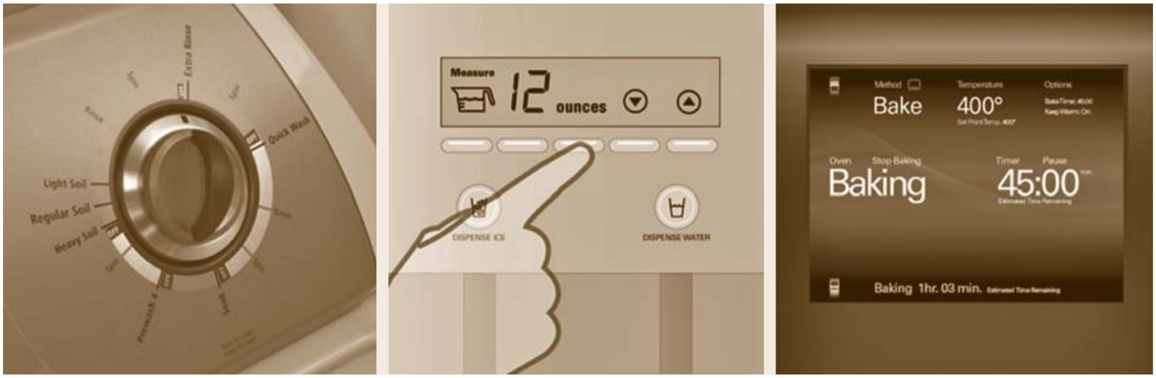


Fig. 83.15 Appliance I/O device evolution

terconnectivity is emerging as a major area of research and development in the home appliance industry.

Smart Resource Usage

We have discussed at length the initiatives on the front of home appliance automated electric power conservation. While home appliances become more convenient, they are simultaneously becoming more efficient and more intelligent in their use of electricity, the culmination of which being automated energy management.

Beyond electricity, questions about supply and price of water and natural gas are driving improvements in efficiency on those fronts. From the user's perspective, such savings are automated, realized internally by advanced software algorithms, mechanical techniques, and materials within the home appliance.

83.3.2 Challenges

Retail Cost

Home appliances are consumer products and, as such, are highly dependent on sales volumes. In some cases, an appliance only becomes profitable to produce if hundreds of thousands – or millions – of units can be sold. Competition is fierce and only grows more intense as time goes on. Thus, tremendous efforts are put into minimizing costs.

All the technology presented here – sensors, displays, and communication electronics – add cost to the appliance. This creates a significant barrier to the introduction of such advancements on a large-scale basis. Consider that a mere dollar of additional cost to an appliance could result in the loss of hundreds of thousands of dollars of revenue for the manufacturer. (Note that retail prices are set by the market, not by the manufacturer, so additional manufacturing costs cannot necessarily be passed onto the consumer.)

Thus, costs represent a significant challenge to the deployment of advanced automation techniques in home appliances. Whereas the value of having – say – a clothes washer is obvious to most consumers, the value of having an interconnected washer is less so. The home appliance industry is thus tasked with convincing consumers that the added value provided by advanced-automation appliances justifies the incremental cost.

Personal Control and Privacy

Consumers are used to having full control over their appliances: When the *start* button is pressed, the machine should start operating. Advanced automation requires that users cede some of this control either to the local machine or to some other remote device. Consumer acceptance of this paradigm will require significant education on the part of appliance manufacturers. It is likely that, in order to achieve consumer acceptance, the ultimate control for appliance behavior will have to remain in the hands of the consumer, with the appliance and other control systems simply providing *suggestions* for machine operation.

Further, the introduction of interconnectivity might present privacy concerns. It is not clear whether consumers would be receptive to the notion of their home appliances automatically relaying information to the Internet, nor to the idea of an Internet node (e.g., the electric utility) remotely accessing information in their appliances. In order to gain consumer acceptance, appliance manufacturers will need to assure consumers of the nature and security of the information being exchanged. This will almost certainly involve using common Internet information security techniques to ensure data privacy.

Standardization and Interoperability

Particularly in the case of interconnectivity, standard implementation methods are required. If, for example, the electric utility is to implement DLC, it is not practical for the utility to use a different communication protocol for each appliance vendor and each appliance model. Further, in the case in which appliances from different vendors within a single home must communicate with each other, the appliances cannot be expected to know each other's proprietary protocols. In sum, a universal communication protocol is required. At the time of this writing, standardization efforts are underway both within the International Electrotechnical Commission (IEC) and within the Association of Home Appliance Manufacturers (AHAM) on this topic. The outcome should be a standard for home appliance communication that permits full intervendor interoperability.

84. Service Robots and Automation for the Disabled/Limited

Birgit Graf, Harald Staab

The increasing number of elderly people is resulting in increased demand for new solutions to support self-initiative and independent life. Robotics and automation technologies, initially applied in industrial environments only, are starting to move into our everyday lives to provide support and enhance the quality of our lives. This chapter analyzes the needs of disabled or limited persons and discusses possible tasks of new assistive service robots. It further gives an overview of existing solutions available as prototypes or products. Existing technologies to assist disabled or limited persons can be grouped into stand-alone devices operated by the user explicitly such as robotic walkers, wheelchairs, guidance robots or manipulation aids, and wearable devices that are attached to the user and operated implicitly by measuring the desired limb motion of the user such as in orthoses, exoskeletons or prostheses. Two recent developments are discussed in detail as application examples: the robotic home assistant Care-O-bot and the bionic robotic arm ISELLA. One of the most important challenges for future developments is to reduce costs in order to make assistive technologies available to everybody. On the technological side, user interfaces need to be designed that allow the use of the machines even by persons who have no technical knowledge and that enable new tasks to be taught to assistive robots without much effort. Finally, safe manipulation of assistive robots among humans must be guaranteed by new sensors and corresponding safety standards.

In the last years, the percentage of elderly people in our society has grown rapidly. Out of 82.5 million people living in Germany in 2005, according to numbers from the German Federal Statistical Office, around 19% were seniors above 65 years [84.1]. With this demographic development continuing, by the year 2050 those above 65 years will comprise 33–36% of Germany's population. Similar numbers are reported from other industrial nations all over the world, in particular the USA and Japan. Many disabilities come with age. In order to provide sufficient support for the growing number of disabled persons, new solutions to assist these people are required.

84.1 Motivation and Required Functionalities

Technical aids enable people in need of support and care to live independently in their accustomed home environments for a longer time. As not all homes are suitable for installing intelligent home technologies as described in Chap. 83, mobile service robots able to navigate and operate in existing homes without modifications to the environment provide a more flexible solution. Such service robots not only fulfill the user's desire for independence and autonomy, but also help to avoid the high costs of individual treatment in nursing homes that might otherwise be necessary.

The task of a service robot or other automation technologies for the disabled and limited is to provide support and instructional help in a person's daily life and to promote self-initiative. The group of target users for such new technologies includes:

- Elderly and frail persons
- Disabled persons (physically, psychically)
- Severely sick persons (heart attack, plastered leg)
- Chronically sick persons (diabetes, epilepsy)
- Severely restrained persons (e.g., pregnancy).

Due to the fact that humans have for a long time dreamt of an assistant to relieve them of difficult handling tasks, the basic concept of service robots assisting people in their daily life has been presented and their functionalities been described long before they were actually built. The requirements that a service robot to assist the disabled must cope with and the corresponding technical abilities can therefore be specified precisely [84.2, 3]. Some of the most important tasks, identified by a study done with elderly people and their care-givers, are summarized below.

Household Tasks

- Execute everyday jobs such as serving drinks, setting the table, operating the microwave, simple cleaning tasks
- Fetch and carry objects, e.g., books, remote control, medicine
- Support in grasping, holding, and lifting objects and tools
- Control of the technical home infrastructure, e.g., heating system, air-conditioning, lights, windows, doors, alarm system, etc.

Mobility Aid

- Support for standing up from the bed or a chair
- Controlled motion
- Obstacle detection and guidance to a target.

Communication and Social Integration

- Media management (videophone, TV, stereo, interactive media, etc.)
- Daytime manager (daily routine, time for medicine, etc.)
- Communication with medial and public facilities (physician, authorities, etc.)
- Supervision of vital signs and emergency call functionality.

84.2 State of the Art

In recent decades, and continuing to the present day, service robots for the disabled and limited is an active field of research and development, performed in many countries throughout the world. Main research is carried out at universities and research institutes, covering a brought range of ideas, approaches, and technologies. The landscape of companies in this branch seems to be twofold: on the one hand there are a few large players, who have been providing orthopaedics solutions in large numbers and for many years already, trying to introduce robotics into some of their high-end products. On the other hand there are many smaller high-technology companies, often launched by researchers in this field, focusing on a few or a single product solution.

This section provides a representative overview of the state of the art in the field of assistive robotic devices for the disabled and limited. The following examples may be understood as representatives of many more but similar developments. For further insights one may refer to proceedings of international conferences such as those on Robotics and Automation (ICRA), Intelligent Robots and Systems (IROS), Robotics and Applications (RA), and others that usually host large sessions on assistive and rehabilitation robotics. The International Conference on Rehabilitation Robotics (ICORR)

Fig. 84.1 Classification of service robots and automation for the disabled

is focused on this topic alone. Other sources may be periodicals such as the quarterly *International Journal of Rehabilitation Research* (IJRR), the monthly *International Journal of Therapy and Rehabilitation* (IJTR), the quarterly *International Journal of Medical Robotics and Computer Assisted Surgery*, and others.

Existing service robots and assistive devices for the disabled and limited can be grouped into stand-alone devices, operated by the user explicitly such as robotic walkers, wheelchairs, guidance robots or manipulation aids, and wearable devices that are attached to the user and operated implicitly by measuring the desired limb motion of the user such as in orthoses, exoskeletons or prostheses. A similar classification is found in [84.4]. Figure 84.1 summarized this classification of service robots and assistive devices for the disabled and limited.

The review of existing solutions starts in Sect. 84.2.1 with mobility aids such as robotic walkers or robotic wheelchairs providing autonomous or semiautonomous navigation capabilities. Section 84.2.2 describes existing guidance robots that may be applied for blind persons or those suffering from dementia and other mental disorders. From the technical viewpoint they are quite similar to robotic walkers but the focus of these systems is on cognitive, not physical support. Section 84.2.3 describes existing manipulation aids that may be either static, such as in desktop-mounted manipulators, or mobile when attached to a wheelchair or to another kind of mobile platform.

Finally the group of wearable devices is reviewed. Section 84.2.4 describes orthoses and exoskeletons for users who need direct support in moving their limbs. Prostheses worn by a user to replace amputated limps are increasingly incorporating robotic features and are reviewed in Sect. 84.2.5.

84.2.1 Mobility Aids

Robotic Walkers

Robotic walkers are enhanced off-the-shelf walkers equipped with robot technology such as environment sensors and drives. Using these technologies, they are able to provide additional support to their user, ranging from audio or visual information on the environment to autonomous or semiautonomous navigation. For existing robotic walkers, two basic types can be distinguished: passive and active robotic walkers.

Passive robotic walkers do not have any driven wheels and move directly according to the applied user forces (direct user control). Examples of passive walkers are the COOL Aide [84.5] (Fig. 84.2a) and PAMM-AID [84.6] systems, which use motorized steering of the wheels to lead the user around obstacles. The RT-Walker [84.7] uses special servo brakes to steer the device in a collision-free direction. In case no obstacles are detected the user has full control of the device and can move it, similarly to a conventional walker. Most passive systems are equipped with brakes to stop them if they get too close to an obstacle or step. A guidance system for Guido, the commercial successor of PAMM-AID, has been presented [84.8] (Fig. 84.2b). After a target has been set, the robot will plan and follow a path to the target. During guidance the desired direction indicated by the user input will be ignored. The successor of the RT-Walker, ORTW-II [84.9], uses a *potential canal* method which only allows deviations up to a certain distance from the optimal path to the target. The robotically augmented walker developed at Carnegie Mellon University (CMU) [84.10] (Fig. 84.2c) does not use its motors when traveling with a user but tracks its position and displays the optimal direction

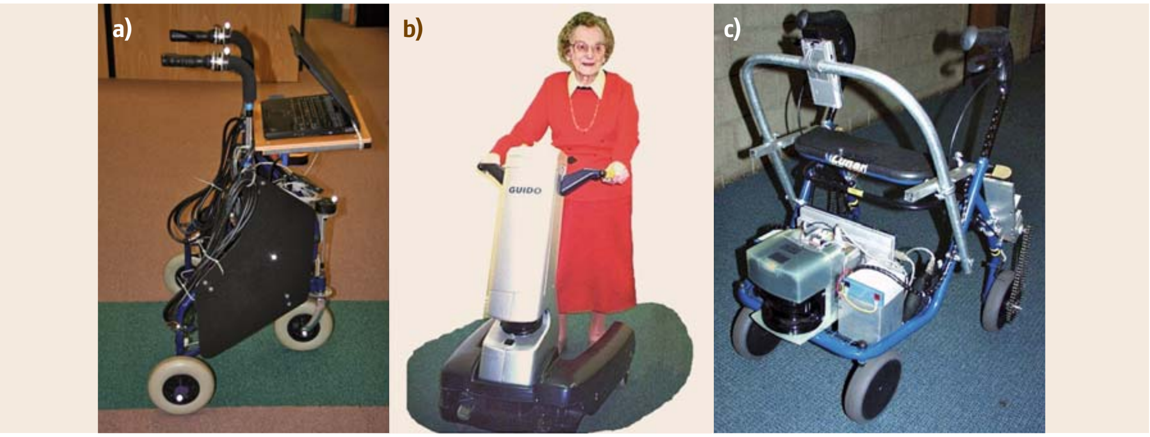

Fig. 84.2a–c Examples of passive robotic walkers: **(a)** COOL Aide (courtesy of the University of Virginia, USA), **(b)** Guido (courtesy of Haptica Ltd., Dublin, Ireland), and **(c)** CMU robotically augmented walker (courtesy of Carnegie Mellon University, Pittsburgh, USA)

of travel on a screen to guide its user to the selected target.

Active robotic walkers are equipped with motorized wheels. Force or force-torque sensors of different kinds are used to determine the forces applied to the system by the user. These forces are used to calculate the desired driving direction and speed of the walker (indirect user control). Some systems (Silbo [84.11] (Fig. 84.3a), Hitachi walker [84.12], RT-walker) are equipped with angle sensors, enabling the required force input to be adapted on slopes. All systems are able to detect obstacles and stop in front of them; most of them adapt the traveling direction to surround obstacles in advance. The PAMM smart walker [84.13] (Fig. 84.3b) and the CMU robotic walker [84.14] (Fig. 84.3c) are able to localize themselves in their environment and thus plan an optimal path to a given target. The shared control system of PAMM creates a virtual force, leading the robot to the given target, which is combined with the real forces applied to the device by the user. The gains of each control input are set depending on the observed user abilities. Whereas for PAMM an interface providing feedback to the user on the planned path has not been presented, the CMU robotic walker displays the desired direction of travel on a screen. The user is free to move in any direction; however, if the deviation from the planned path is too large, the velocity of the walker will be reduced to force the user back to the path.

Other robotic walkers focus their works on additional support functions such as lifting assistance (Hitachi walker, Monimad walker [84.15], MOBIL Walking & Lifting Aid [84.16], Walking helper II [84.17]), person tracking (MOBIL Test Bed [84.18]) or moving out of the way when not used (CMU robotically augmented walker).

Robotic Wheelchairs

Similar to robotic walkers, robotic wheelchairs provide enhanced safety and/or improved navigation capabilities using mobile robotics technologies. Robotic

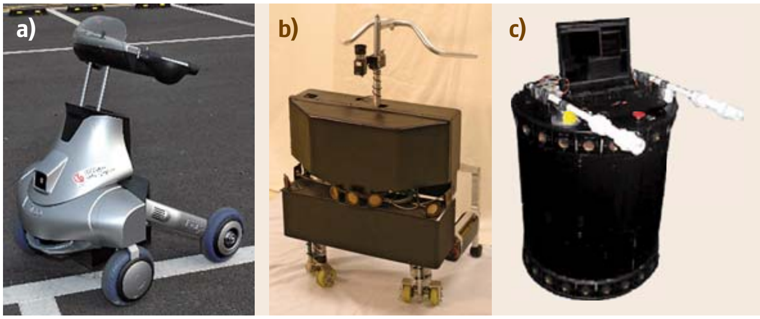

Fig. 84.3a–c Examples of active robotic walkers: **(a)** Silbo (courtesy of Intelligent Healthcare Laboratory, Korea), **(b)** Smart walker PAMM (courtesy of Massachusetts Institute of Technology, USA), and **(c)** CMU robotic walker (courtesy of Carnegie Mellon University, Pittsburgh, USA)

wheelchairs are based on electric wheelchairs where control over the drives is at some point taken over by the integrated personal computer (PC). In order to perceive the environment, robotic wheelchairs are equipped with environment sensors such as sonar sensors or laser scanners. Existing control systems for robotic wheelchairs can be divided into two basic types [84.19]: model-based approaches and behavior-based approaches.

Model-based shared control systems analyze the input of the user and the measured environment data in order to identify the intended travel direction of the user and thus adapt the motion of the wheelchair. To identify the intention of the user, the current sensor input of the user, e.g., the position of the joystick, is compared with a previously recorded motion model and an appropriate action is selected. The robotic wheelchairs NavChair [84.20] or VAHM [84.21] use a method that generates a histogram of the environment identifying the optimal direction of travel (minimum vector field histogram, MVFH). The user is responsible for high-level control of the system, such as route-planning and some navigation actions, while the machine overrides unsafe maneuvers through autonomous obstacle avoidance. It can provide addition assistance, e.g., for safely passing narrow passages such as doors. The MVFH algorithm ensures that the input of the user is considered at all times and thus the user always feels in control of the wheelchair. SmartChair [84.22] is another representative of model-based shard control systems. This robotic wheelchair is not only able to adjust the input of the user for collision-free motion; it further provides localization and path-planning capabilities to guide the user to a previously specified target. SmartChair uses a potential field method to calculate a suitable motion direction to the given target. MAid [84.23] is an autonomous wheelchair able to safely pass crowded environments, however, at the cost of not considering the input of the user during motion.

Behavior-based shared control systems assume that the driving behavior of the robotic wheelchair can be classified into a few basic tasks such as high-speed driving, close-quarter manoeuvring, and docking manoeuvres. From the input of the user and the measured environment data, a suitable motion behavior is selected. The crucial factor in behavior-based shared control systems is to find out which behavior is currently most appropriate. Wheelsley [84.24] is a robotic wheelchair based on the well-known behavior-based subsumption architecture [84.25]. In free space, the robot moves along with maximum velocity in the direction indicated by the user. If an obstacle in the desired motion direction is detected, obstacle avoidance behavior is activated to pass by the obstacle. Similar approaches are applied in the Rolland [84.26] (Fig. 84.4a), RobChair [84.27], and Sharioto [84.28] projects. Some motion behaviors conflict with each other, such as passing a narrow passage and obstacle avoidance. Another conflict occurs if the user wants to dock to an object while at the same time collision avoidance is required. For docking to an obstacle, in [84.28] the user's confidence when guiding the wheelchair in a specific direction is evaluated. Only if the user moves straight and without fluctuations towards an obstacle will the direction be maintained.

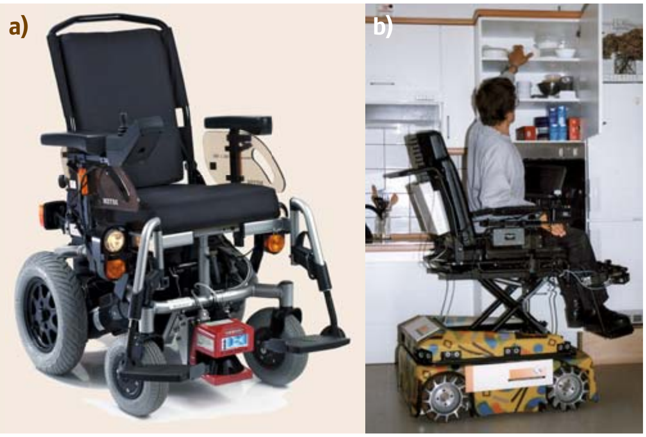

Fig. 84.4a,b Examples of advanced robotic wheelchairs: **(a)** Rolland III (courtesy of the DFKI-Labor, Bremen, Germany) and **(b)** OMNI (courtesy of Forschungsinstitut Technologie und Behinderung der Evangelischen Stiftung Volmarstein, Germany)

Other robotic wheelchairs such as the office wheelchair with high manoeuvrability and navigational intelligence for people with severe handicap (OMNI) [84.29] (Fig. 84.4b) provide advanced assistance through omnidirectional navigation capabilities and height adjustment. The special mechanics of the iBOT (http://www.ibotnow.com/) enable stair-climbing. Even legged chairs such as i-foot, one of the partner robots by Toyota designed to assist people [84.30], which is able to move along in uneven terrain, have recently been introduced.

84.2.2 Guidance Robots

Guidance robots are used to assist people with mental weaknesses and diseases or blind people. Guidance robots for the blind require direct physical contact to the user. One of the first robotic guidance systems

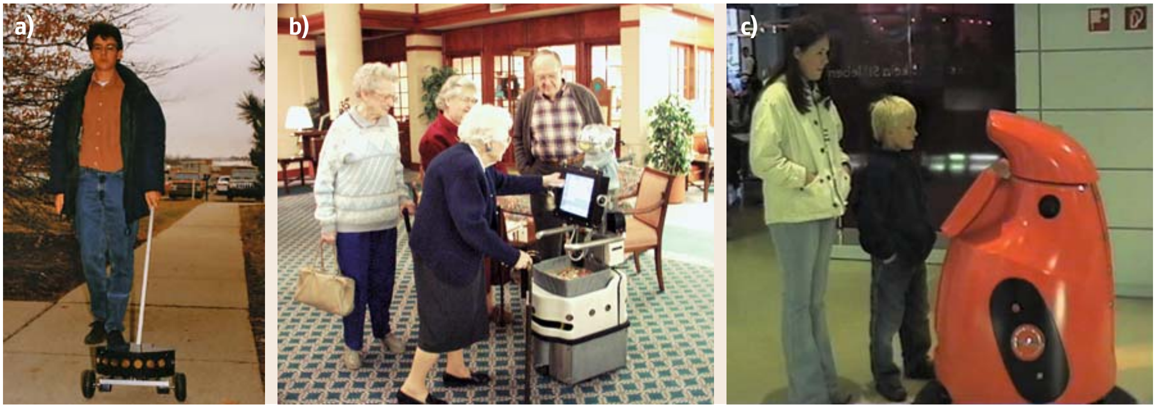

Fig. 84.5a–c Examples of guidance robots: **(a)** GuideCane (courtesy of University of Michigan, USA), **(b)** Nursebot (courtesy of Carnegie Mellon University, Pittsburgh, USA), and **(c)** exhibition guide MONA by Fraunhofer IPA, Germany

is the NavBelt [84.31], a device worn by the user. Equipped with sonar sensors, NavBeld is able to detect obstacles in front of the user and issue a warning. GuideCane is the cane-based continuation of this research (Fig. 84.5a). In contains a small mobile robot as a base that carries the environment sensors and a cane that the user can hold onto. Using a small joystick, the user indicates the desired travel direction and is led along by the robotic base. If an obstacle is detected by the sensors, the path will be modified to lead the user around the obstacle safely.

Other guidance robots are designed to assist the elderly, for example, to guide them to specific locations in elderly care facilities. In this case, no direct contact with the user is required. Nursebot [84.32] (Fig. 84.5b) is a development that targets this application. Guidance robots with similar capabilities are also applied in museums or exhibitions [84.33] (Fig. 84.5c).

84.2.3 Manipulation Aids

Manipulation aids are applied to assist disabled users in eating, drinking or object replacement. This Section describes existing fixed- or portable-platform manipulators as well as existing autonomous mobile robots with manipulation skills.

Fixed-Platform Manipulators

The professional vocational assistive robot (ProVAR) [84.34] is a research prototype designed to assist individuals with a severe physical disability. The system consists of an industrial manipulator attached to an overhead track suspended above a worktable and is able to handle objects for a user who has difficulties in handling these objects himself. The manipulator is controlled by voice commands or head motion inputs. The robot to assist the integration of the disabled (RAID) [84.35] is a robotic workstation for use by individuals with little or no upper-limb function in office environments. It is based around a custom-designed mechanical structure providing storage for books, manuals, paper documents, and other reference materials. A robot arm is mounted on a linear track in front of the storage zones. It is able to assist the user, e.g., to transport books or diskettes or to hold a book and turn pages when reading it. The arm's working envelope includes a large proportion of the desk area but does not reach to the user for reasons of safety.

Portable-Platform Manipulators

Portable platform manipulators include manipulators attached to a mobile base with castor wheels that can be rolled around and wheelchair-mounted manipulators. Handy1 [84.36] (Fig. 84.6a) is an example of the first group of assistive manipulators. It consists of a robot arm and a tray that can be selected for several applications such as feeding, cleansing, and make-up. The robot is controlled by a switch input used in conjunction with a linear scanning control system which is suitable for different disability groups. The assistive robot service manipulator (ARM), which is also known as *Manus* [84.37] (Fig. 84.6b), is a $6+2$ degree of freedom (DOF) robot that assists disabled people with a severe handicap of their upper limbs. It compensates their lost arm and hand function. It can be mounted on an electric wheelchair (or mobile base) and allows numerous daily living tasks to be carried out in the home, at work, and outdoors. By means of an input device such as a keypad (4 × 4 buttons), a joystick (e.g., of the wheelchair) or another device attached to a nondisabled body part, the manipulator can be operated to grasp objects with its gripper.

Mobile Autonomous Robots with Manipulation Skills

Mobile autonomous robots with manipulation skills are a popular topic of current research. Even though research in this field has grown significantly over recent years, no commercial products have been placed on the market so far. Among existing prototypes, two basic approached can be observed: human-like robots equipped with legs and arms and wheel-based robots.

Humanoid robots with legs are most popular in Japan. Most of the currently existing prototypes are not specifically designed to assist disabled people. However, for many robot developers, this application is seen as one of the most important for future products. The partner robots developed by Toyota [84.30], for example, were first demonstrated at EXPO 2005 AICHI, Japan. During the EXPO they were applied to entertain the visitors of Toyota's pavilion by playing different instruments. However, this was only the first step towards the creation of robots that can use tools, assist people, and live in harmony with us. According to the partner robot developers, currently, new robots are being developed that can provide elderly care to help Japan cope with its rapidly aging population. The goal of the ASIMO [84.38] (Fig. 84.7a) development of Honda is quite similar: to develop a robot that can duplicate the complexities of human motion and genuinely help people. Even though ASIMO is mainly used as a research platform at the moment, someday ASIMO might help with important tasks such as assisting the elderly or a person confined to a bed or a wheelchair. HRP-2 [84.39] (Fig. 84.7b) by Kawada and the US-American SARCOS [84.40] humanoid robot are similar platforms that can be used for experiments to further develop robotic technologies developments.

One of the first wheel-based robots able to assist disabled people with daily tasks is MOVAID by the Scuola Superiore Sant'Anna in Italy [84.41]. The robot is able to navigate in homelike environments and to perform simple manipulation tasks. Another early development is Hermes [84.42], developed at the Bundeswehr University Munich. Hermes is able to explore unknown environments, to fulfil transportation and manipulation tasks in spacious human-populated areas, and to interact and communicate even with novice users in a natural and intuitive way. Research on assistive robots is currently being performed in several projects in Germany such as the Collaborative Research Center on Humanoid Robots in Karlsruhe [84.43], where several generations of the ARMAR platform (Fig. 84.7c) have been set up in the last years. One of the most advanced developments in wheel-based robotic home assistants is the German Care-O-bot [84.44] which will be described in detail in Sect. 84.3.

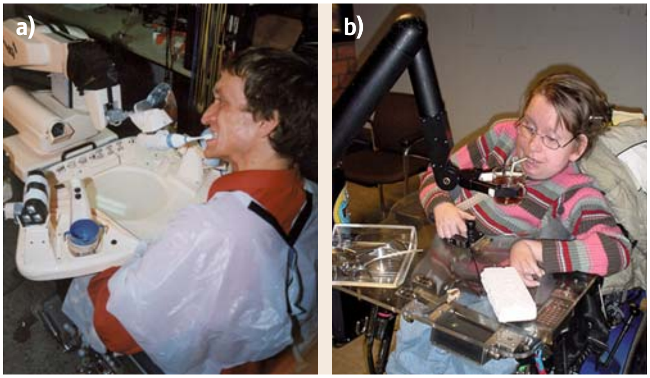

Fig. 84.6 (a) Portable-platform manipulators Handy1 (courtesy of Forschungsinstitut Technologie und Behinderung der Evangelischen Stiftung Volmarstein, Germany) and **(b)** ARM (courtesy of Exact Dynamics BV, Netherlands)

Recent developments of wheeled robots in Japan include the excellent mobility and interactive existence as workmate (EMIEW) by Hitachi [84.45] and Smart-Pal by Yaskawa [84.46]. At the EXPO 2005 AICHI, Japan, they were introduced in a bar scenario, where they demonstrated their abilities to serve drinks to visitors. By now, for each robot, the second generation has recently been introduced. Another interesting Japanese development is enon (*exciting nova on network*) by Fujitsu [84.47], designed for duties such as providing guidance, transporting objects, and security patrolling. In Japan, limited sales of enon have already been announced.

84.2.4 Orthoses and Exoskeletons

Orthoses are understood as orthopaedic devices to support parts of the body with reduced mobility. There are those for fixation at reversible or nonreversible deformations and bad postures as well as for recovery (e.g., ruff). Others are used to support, e.g., arch supports and orthopaedic corsets. The latter are said to be passive if they support only, and active if they force the body

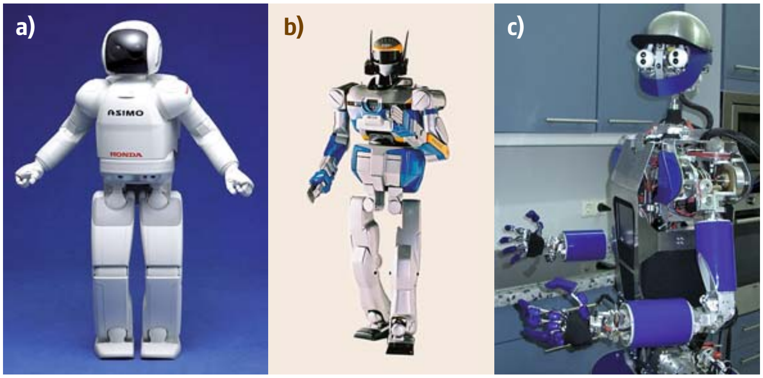

Fig. 84.7a–c Popular humanoid and wheel-based robots with manipulation skills: **(a)** ASIMO (courtesy of Honda Motor Co., Ltd., Japan), **(b)** HRP-2 (courtesy of National Institute of Advanced Industrial Science and Technology, Japan), **(c)** Armar 3 (courtesy of the Collaborative Research Center 588 Humanoid Robots – Learning and Cooperating Multimodal Robots, Karlsruhe, Germany)

to actively correct, e.g., mis-statics of the spine. Any orthoses usually requires significant fine-tuning in order to meet the body conditions as well as the medical demands of an individual.

Utilizing robotics for orthoses is limited to a few application examples and there is a fuzzy border towards the prostheses domain, however there is some research and development (R&D) purely for orthoses. Most researchers focus on rehabilitation, e.g., of stroke patients. Sometimes an orthosis may look quite simple at first sight, but there may be a lot of *complexity* and careful thoughts behind any combination of materials, part design, and choice of mechanisms. An earlier example is the Wilmer elbow orthosis [84.48], a passive foot-drop orthosis from the University of Hawaii-Manoa, USA [84.49], and numerous stationary passive or motor-powered *gravity-compensation* rehabilitation devices for the upper extremities such a dynamic arm support [84.50], Freebal [84.51] (Fig. 84.8a), and iPAM [84.52]. Some orthoses are equipped with elaborated spring and lever mechanisms, brakes, and may also be motor-powered with advanced control algorithms such as a foot orthosis from the University of Osaka, Japan [84.53], and a knee orthoses from the Vrije Universiteit Brussels, Belgium, powered by pneumatic artificial muscles [84.54].

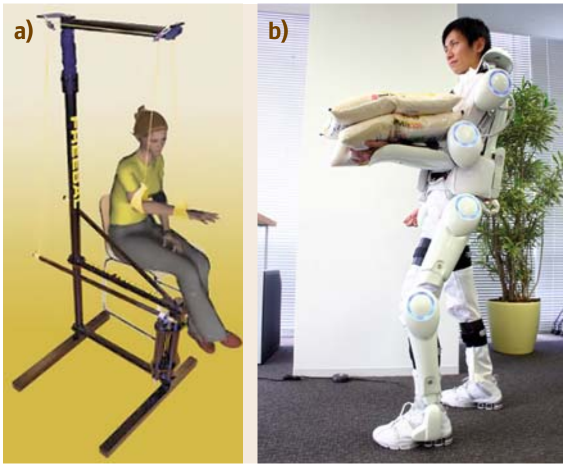

Fig. 84.8 **(a)** Freebal (courtesy of Baat Medical, Hengelo, Netherlands) and **(b)** Hybrid Assistive Leg (HAL, courtesy of Tsukuba University/Cyberdyne Inc., Japan)

There are also quite complex, full-body gait rehabilitation systems such as HapticWalker [84.55], STRINGMAN [84.56], and LOKOMAT [84.57], which are composed of a stationary frame, a hanging harness for the patient to put on, and possibly a treadmill. Current R&D covers mechanical design as well as extending the functionalities of existing systems regarding sensing, control, haptic feedback, artificial intelligence, and virtual reality.

The term *exoskeleton* is also often used for powered orthoses, but it is not only limited to medical applications. There are those for a single extremity (upper or lower), or covering one or few joints, e.g., knee and ankle. And there are those for full-body motion support, either stationary or mobile. Some examples are ALEX (stationary, for gait rehabilitation) [84.58], BLEEX (mobile, for military use to increase payload of a soldier carrying equipment) [84.59], and the Hybrid Assistive Leg (HAL, mobile, full-body exoskeleton, Fig. 84.8b) [84.60].

84.2.5 Prostheses

While orthoses and exoskeletons are attached to existing parts of the body, prostheses are replacements of lost extremities. Most sold prostheses of arms and hands are purely cosmetic, whereas most prostheses of legs and feet are passive but functional, i. e., they enable patients to walk. However, scientific R&D as well as commercial high-end products clearly aim at coming close to the functionality of the replaced body part. This means motorization, haptic perception, and reliable and comfortable control by the patient. Some advanced commercial prostheses of fingers or the entire hand are the i-LIMB [84.61] and the Fluidhand [84.62], and of the leg are the c-leg [84.63] and the Powerknee [84.64].

Beside commercial developments there are a number of prostheses in research. Focus is placed on powered prostheses and their mechanical and mechatronic design, signal interfaces to the human body for control and feedback, and advanced motion control. There are developments for upper [84.65] (Fig. 84.9) and lower limbs; some examples of recent lower-limb developments are powered ankle–foot and knee prosthesis as described in [84.66] and [84.67].

84.3 Application Example: the Robotic Home Assistant Care-O-bot

84.3.1 History of Care-O-bot Development

Care-O-bot is a mobile robot assistant designed of Fraunhofer IPA, Germany to assist people in daily life activities. Three Care-O-bot robots have been developed so far: The first Care-O-bot prototype (Fig. 84.10a) [84.68] was built in 1998, when the idea of building rehabilitation robots was still new. Care-O-bot I is a mobile platform with a touchscreen, able to navigate autonomously and safely in indoor environments, and communicate with or guide people. As a mobile platform alone, it can be used for transportation and safeguarding tasks; however, it is unable to execute complex manipulation tasks as required from a home assistant. Care-O-bot II (Fig. 84.10b) [84.69], built in 2002, is additionally equipped with a manipulator arm, adjustable walking supporters, a tilting sensor head containing two cameras and a laser scanner, and a handheld control panel [84.70]. The manipulator arm, developed specifically for mobile service robots, provides the possibility of handling typical objects in a home environment. A flexible gripper attached to the manipulator is suitable for grasping various objects such as mugs, plates, and bottles. A handheld control panel is used for instructing and supervising the robot. In addition to all mobility functions already solved in Care-O-bot I, the second prototype is able to execute manipulation tasks autonomously and can be used as an intelligent walking support. Care-O-bot 3 (Fig. 84.10c), built in 2008, is the latest generation of this successful development series. It is equipped with the latest state-of-the-art components including omnidirectional drives, a seven-DOF redundant manipulator, a three-finger gripper, and a flexible interaction tray that can be used to safely pass objects between the human and the robot. Its moveable sensor head contains range and image sensors enabling autonomous object learning and detection and three-dimensional (3-D) supervision of the environment in real time.

84.3.2 Key Technologies

Autonomous or Semiautonomous Navigation

All Care-O-bot prototypes are able to navigate autonomously to a given target [84.71]. Autonomous navigation is a key issue in order to execute a fetch and carry task or to guide the user to a specific location. Chapter 16 has additional insights in automation mobility and navigation. A static environment map is used to plan an optimal path to the given target. Different approaches for global planning have been implemented and can be selected according to the geometry, kinematics, and current operation mode of the robot [84.72]. The generated path is smoothed and eventually modified in reaction to dynamic obstacles or other external forces. A laser scanner attached to the robot is used for continuous and dependable obstacle detection.

Automatic Object Detection

In order to grasp an object, the robot must be able to detect relevant objects in the environment. This task is solved by combining a range imaging sensor [84.73] with a color camera. The recognition algorithm is based on scale-invariant feature transform (SIFT) descriptors that are recorded for each object and fed into a learning algorithm (a one-class support vector machine, SVM) [84.74]. Using the data of the range imaging sensor, feature keypoints can be segmented from the background. A region in space is effectively masked out in the color image of the scene using the range measures for the corresponding pixels in the range image. New objects are taught to the robot by placing them in front of the sensors and by recording the relevant SIFT keypoints for the object [84.75]. Figure 84.11a displays the teaching of new objects using the proposed range segmentation. Figure 84.11b–d illustrates the learning process and resulting representation of an object: several images of the object are recorded and for each the feature points are detected. In a second step the feature points of all images are fused into a 3-D feature point cloud which again can be used to detect and compute the position of the object in a given scene.

Object Manipulation

Based on the data from the range imaging sensor and the identified location of the object to be grasped, a collision-free trajectory for moving the manipulator to the detected object can be computed. To solve this, the robot and scene are modeled using *oriented bounding boxes* (OBBs). For the robot a distinction is made between static components (e.g., the robot's torso) and dynamic components (e.g., its manipulators). The dynamic components are mapped by articulated models which are updated with each robot movement. The model of the scene is obtained by generating corresponding OBB models from the point cloud obtained by the range sensor. The obstacle model is used as the basis for online collision monitoring. The algorithm consists of two main phases: determination of potentially colliding objects by a rough distance check based on the velocity vectors of all moving parts, and subsequent elaborate collision tests for all objects in the determined potential colliding sets. Figure 84.12a shows the velocity vectors of a moving arm. Figure 84.12b shows the manipulator about to collide with the robot torso; the respective joints are marked in red color. Figure 84.12c shows successful collision detection for simultaneous movement of two manipulators.

In addition to the online collision monitoring, the obstacle model provides the basis to compute

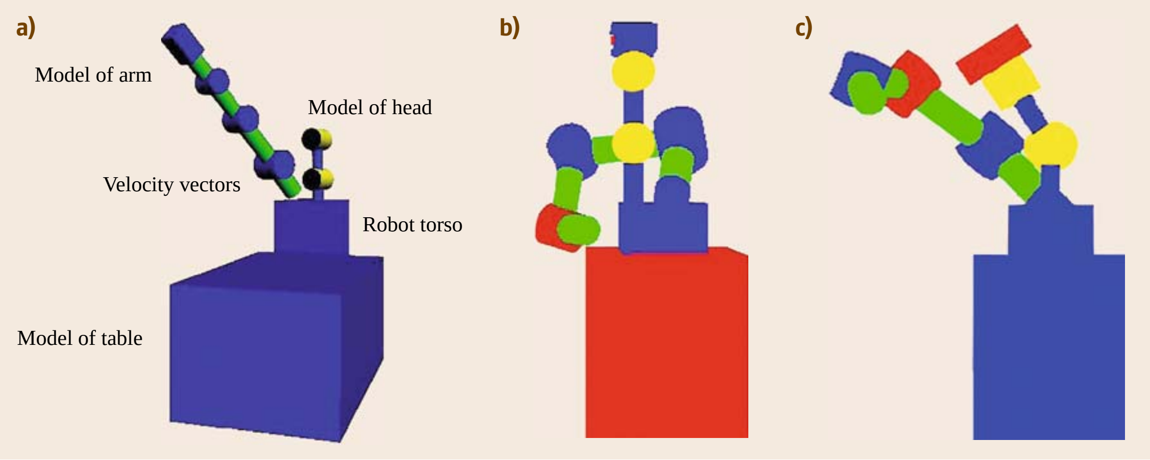

Fig. 84.12a–c Velocity vectors of moving parts (**a**), detection of potential collisions between different parts of the robot illustrated in red color (**b,c**)

a collision-free trajectory for moving the manipulator to grasp a previously detected object. The entire obstruction model is used as the basis for the path search. As a result the determined path is guaranteed to be collision free with respect to both the robot's components and also the robot's environment. The implemented method is based on path planning with rapidly exploring random trees [84.76], and smoothing of the calculated path.

User Interface

In order to enable all users to operate Care-O-bot without difficulties, the user interface must be suitable even for users without any prior technical knowledge [84.77]. For simple man–machine communication without misunderstanding, multiple sensing channels (speech, haptics, and gestures) are addressed. Commanding the robot, for example, is done by speech input, gestures, and touchscreen. The necessary feedback about the robot system state is given by speech output and graphical presentations on the monitor. The user interface of Care-O-bot II is implemented on a handheld, lightweight control panel, which the user can retain – even while the robot moves around. Care-O-bot 3 provides a moveable tray to pass objects to and from the user. A touchscreen integrated in that tray provides the necessary visual input and output.

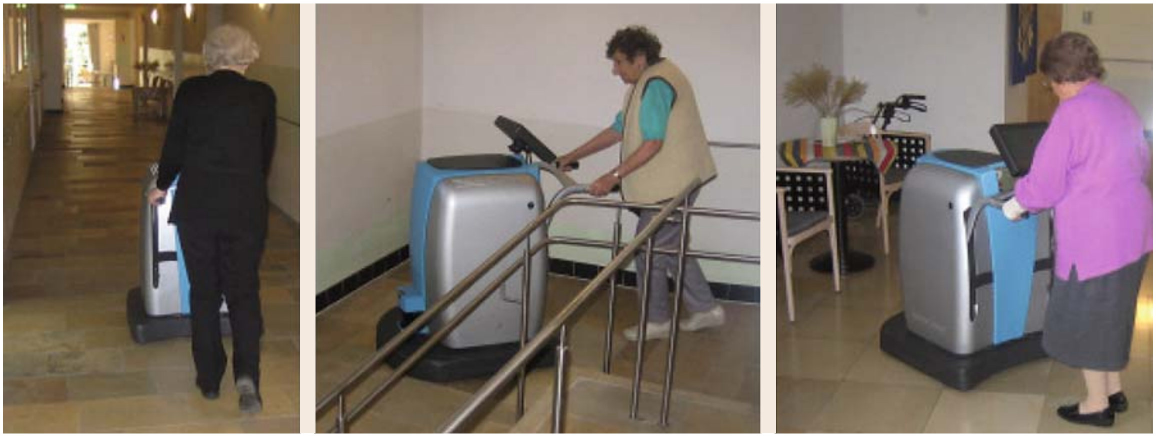

Fig. 84.13 Field tests of the walking aid function

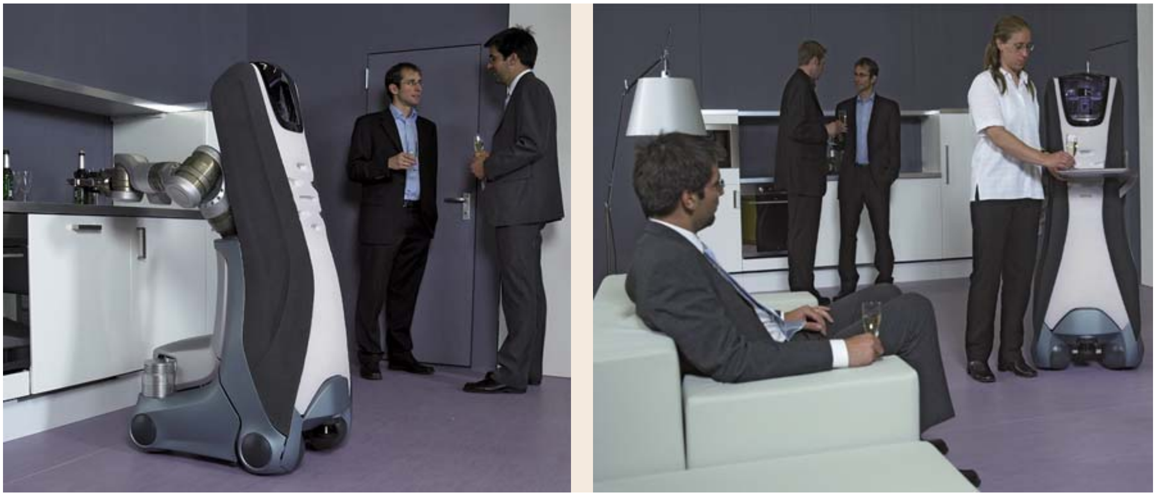

Fig. 84.14 Care-O-bot 3 fetching a drink in the kitchen and serving drinks to visitors

84.3.3 Applications

Walking Aid Function

Using the walking supporters attached to the rear of Care-O-bot II, the robot can serve as an intelligent walking aid able to lead a user to a given target [84.78]. The velocity of the robot during guidance is adjusted to the walking velocity of the user by measuring the user forces applied to the handles. Several user tests in elderly care facilities have proven the capabilities of the guidance system. Figure 84.13 displays some elderly users during the latest field tests. In order to enable a clear view ahead, the sensor head and manipulator of the robot was taken off for the walking aid tests.

Dependable Execution of Fetch and Carry Tasks

The fetch and carry capabilities of Care-O-bot II and Care-O-bot 3 have been tested and evaluated on several occasions during fairs and exhibitions. A sample home environment containing different furniture and objects is used to test, demonstrate, and evaluate the performance of the robots. They are already able to detect, grasp, and move different objects in the environment or bring them to the user (Figure 84.14). Care-O-bot II has also been tested in a real home environment. The robot was ordered to get a drink from the kitchen. It was able to grasp a box of juice from the refrigerator, and a glass from the kitchen shelf and place it on the living room table. Direct user interaction was tested by handing a box of pills to the user.

The tests and demonstrations have proven the dependability of the fetch and carry task execution system: the underlying execution framework ran to our complete satisfaction. Error detection and error recovery of the framework enabled detection and grasping of objects to function without any failures.

84.4 Application Example: the Bionic Robotic Arm ISELLA

84.4.1 Service Robot Arms and Drive Technology

Robot arms of service robots may also act as a paradigm for artificial limbs and rehabilitation aids. Some key features are:

- Low ratio of weight to payload
- High energy efficiency and applicability to battery-powered operation
- Moderate costs of manufacturing and materials in series production.

Conventional arms of service robots have a geared electrical motor for each joint as drives, sometimes built with a sleeve shaft as a cable duct for other drives and the gripper. Based on this layout it was possible to bring down the ratio of weight to payload to approximately 3 : 1 to 1 : 1 with designs highly optimized in weight and careful selection of materials

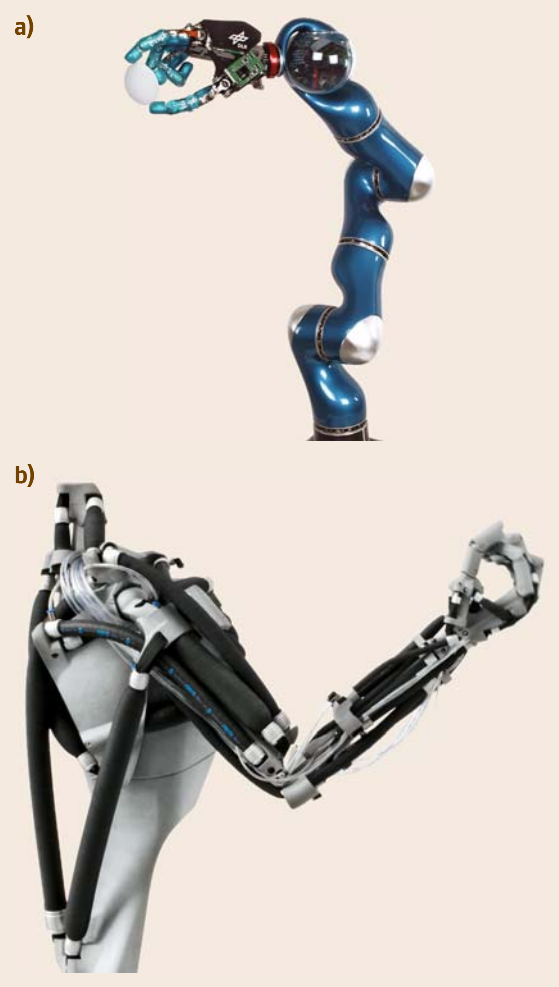

Fig. 84.15a,b Robot arms with high ratio of weight to payload: **(a)** lightweight arm (courtesy of DLR, Wessling, Germany), **(b)** bionic robot arm with fluidic muscles (courtesy of Festo AG, Germany)

(Fig. 84.15). However, costs of production, especially of their high-quality and high-precision drive units, still exceed what may be attractive and affordable for private users, even for medical devices. Moreover, prostheses should have properties similar to their biological counterparts rather than properties of industrial robots. Among others, these properties are variable stiffness of the joints, often smaller ranges of the joint angles, and less precision in forward-controlled positioning of the end-effector. These properties may be easier to achieve with a bionic-oriented approach of mechanical and kinematic design. Secondly, a different approach to drive technology is required, which may be more suitable for variable stiffness and – above all – less expensive.

Something that may be thought of immediately is using artificial or technical muscles, i. e., technical actuators with properties of biological muscles. In recent years and decades a number of different types have been proposed and developed. Most of them are in a state of research, although some are already commercially available. Details and comparisons can be found in several publications [84.79, 80]. The pneumatic muscle, also known as the McKibben muscle [84.81], is a rubber tube covered with a braided tissue that contracts when pressurized. Since some of its properties are different from those of pneumatic cylinders, it is more advantageous for some industrial applications, and has also been used in some bionic robot applications [84.82, 83]. Figure 84.15b shows Airic's arm – an experimental bionic arm by Festo AG, designed like the human arm and shoulder. However, pneumatic systems generally have low energy efficiency compared to electric drives, and also motion control requires precision valves and pneumatic regulators. Another group of artificial muscles is shape-memory alloys (SMA), which change their shape with changing temperature. They are sparsely used for bionic robot applications [84.84]. Electroactive polymers (EAP) are materials with piezoelectric properties. Several hundreds of such polymers are known and some seem promising for use as technical muscles [84.85, 86]. A few demonstrative examples can be found in the field of robotics [84.87]. Beyond these there are some other principles of technical mus-

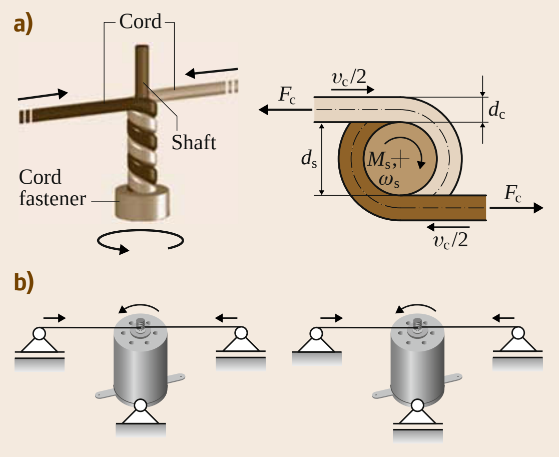

Fig. 84.16 **(a)** Details of the DOHELIX mechanism, **(b)** setup of the DOHELIX muscle

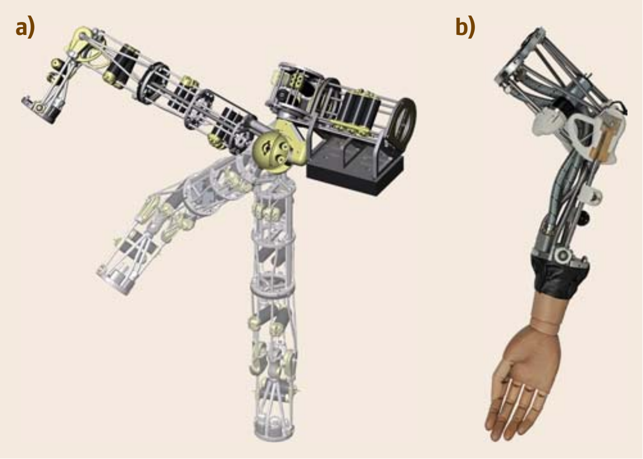

Fig. 84.17a,b The ISELLA robot arm in different poses, assembly of elbow part with a dummy hand

cles [84.88, 89], but these are also in the state of research.

84.4.2 The DOHELIX Muscle

A recent development of Fraunhofer IPA, Germany in the field of artificial muscles may overcome all disadvantages of the above-mentioned drives and may be most suitable for battery-powered articulated mechanisms, including consumer service robot arms, prosthetic devices, and rehabilitation aids. This development was introduced in [84.90] and [84.91], and is shown in Fig. 84.16a. The sketch in Fig. 84.16a illustrates parts and functionality: a highly flexible and high-strength cord is attached to a turning shaft with a cord fastener and it coils onto the thin shaft while pulling both ends of the cord towards the shaft – the muscle is contracting. Using a shaft with a small diameter, high contraction forces with small torques as well as low contraction velocities can be obtained. The torque and rotational speed can be produced by small-size electrical motors and the force can be taken by high-performance plaited cords such as those used in sailing, fishing, and kiting. However, this only works if the cord coils in a single layer, forming a double helix as shown in Fig. 84.16a. For better illustration, the left and right part of the cord are shown in different greyscale, although it is a single cord. The double-helix shape is the origin of the name DOHELIX.

Figure 84.16b shows how the mechanism may be set up in practice, using a simple electrical motor to drive the shaft. Either the motor or one cord end is fixed; the other two assembly points must be linearly moveable. This is a muscle-like actuator in many respects: It can only contract and must be stretched externally, it may be repeatedly overloaded by a multiple of its nominal power, only the motor-coils must not overheat and need time to rest and to regenerate. This is similar to its biological counterpart – a skeletal muscle. After exhausting physical work or sports activity we need time to rest and regenerate our muscles. Unlike gearbox drive solutions, the DOHELIX muscle is only built of a standard motor, a standard cord, and some simple mechanical parts. It is scalable in many respects – size, speed, power, quality, and price.

84.4.3 The ISELLA Robot Arm

When using DOHELIX muscles to design a robot arm, there will be some significant differences to conventional designs, as shown in Fig. 84.15a. Figure 84.17 shows a full design study of the human-arm-like bionic robot arm ISELLA in different poses: hanging down straight and lifted to the side with the elbow bent. It consists of a total of ten DOHELIX muscles, providing a flexor and an extensor for each articulated joint, four situated in the elbow and six in the upper arm. ISELLA is an abbreviation for *intrinsically safe lightweight low-cost arm*. Additional safety compared to conventional design is a consequence of the fact that a single joint only moves with coordinated control of at least two drives. Failure of a single drive control loop is very unlikely to produce uncontrolled motion of the entire arm, since the counterpart of the malfunctioning drive will counteract the motion, trying to maintain the desired joint angle.

Like a human arm without the wrist, ISELLA has five degrees of freedom. The DOHELIX muscles are composed of direct-current (DC) motors and small-ratio planetary gearboxes. With some muscles there are two or three drives in parallel to multiply power while using the same type of motor, cord, and other parts. The elbow part of ISELLA is shown in Fig. 84.16b with a dummy hand attached.

84.5 Future Challenges

The number of assistive devices required will increase with the continuously increasing number of elderly persons. At the same time, the budget available for such assistive tools will be extremely limited. Therefore, one main effort of future developments will be to obtain maximum functionality at minimum cost. One solution could be the use of components already established in other markets such as sensors or motors used in the car industry or industrial applications that are already available at low prices.

Another target for future developments is the design of new human–machine interfaces in order to enable intuitive interaction with technical devices. Current developments deal with speech interaction, gesture recognition or other human-like communication channels. Another aspect for assistive service robots is their ability to continuously learn new tasks. Current developments deal with autonomous robots exploring their environment autonomously or ways of instructing new tasks to a service robot by demonstration or leading it *by the hand*.

A third important aspect of future developments is the issue of safety. Whereas for mobile robots without manipulation capabilities, safety regulations can be derived from industrial applications, specifically the rules for safe navigation of autonomous guided vehicles (AGVs), no rules are yet available for safe manipulation among humans. Currently available products such as the Manus ARM solve this problem by limiting the power of the motors, however, at the cost of not being able to lift heavy objects. In order to provide enhanced support, new sensors have to be applied to supervise the workspace of mobile robot arms in direct interaction with humans.

85. Automation in Education/Learning Systems

Kazuyoshi Ishii, Kinnya Tamaki

The information technology (IT) revolution which began in the latter half of the 20th century has brought great changes to education and learning. The spread of the Internet has made information ubiquitous, changing the emphasis of education from the transmission and acquisition of knowledge to knowledge creation [85.1], and shifting the focus from group to individual education. Since the perspective for discussions of education systems is moving from instructors to learners [85.2–4], in place of *education systems* we adopt the expression *education/learning systems*. When considering the automation of education/learning systems, along with the impact of information and communications technology (ITC), the effects of educational psychology and educational technology cannot be ignored. This field overall is referred to as instructional design (ID) [85.5]. This chapter examines the history and present conditions of automation in education/learning systems, centered on e-Learning, from the perspectives of information and communication technologies and instructional design. The chapter also introduces two examples from the field of industrial engineering and management systems concerning projects to develop education/learning programs to train Japanese manufacturing management personnel. These examples are both ongoing industry–government–academia collaboration projects aimed at the transmission and development of Japanese manufacturing *kaizen* (continuous improvement) knowhow and the education and training of management personnel.

The chapter concludes with a summary of future issues concerning the automation of education/learning systems and a list of reference materials in related fields for readers who seek further details.

85.1 Technology Aspects of Education/Learning Systems

85.1.1 Overview of Instructional Design (ID)

There has been a great deal of discussion regarding the definition of instructional design (ID). (Refer to *Martin Ryder*'s site [85.5] for a comprehensive review.) Here, we introduce two definitions; the first one is from the Applied Research Laboratory (ARL) at Penn State University [85.6]:

> *Instructional design as a process is the systematic development of instructional specifications using learning and instructional theory to ensure the qual-*

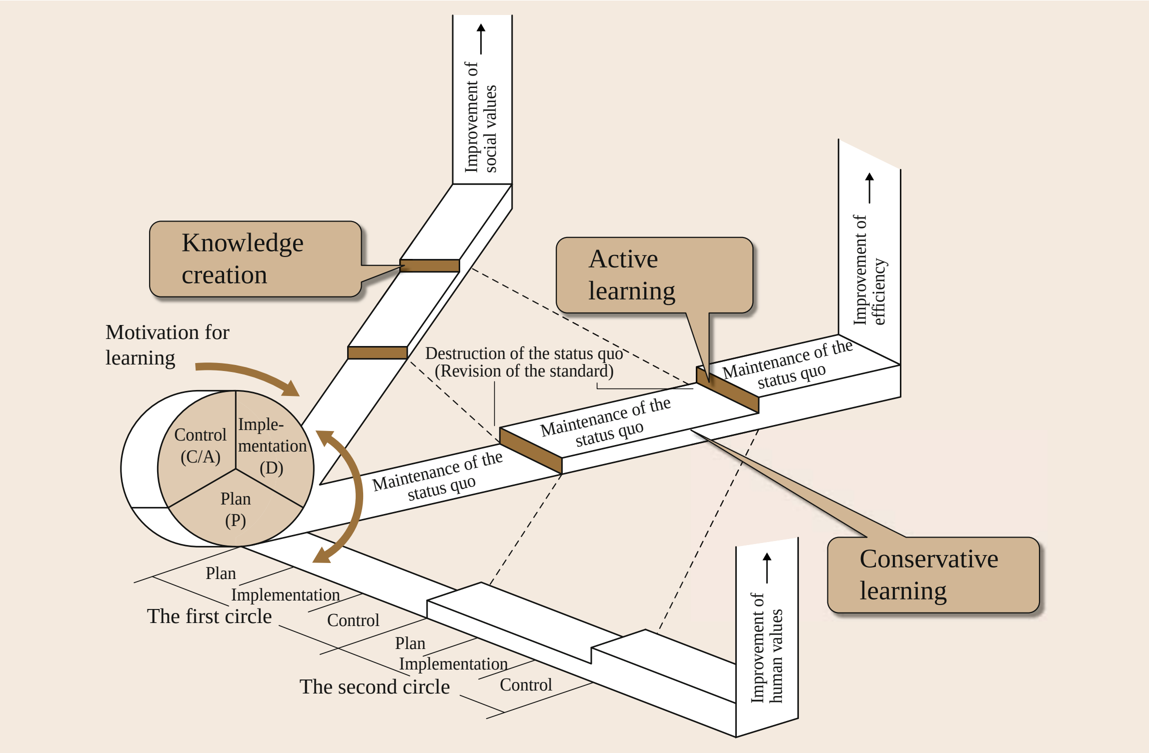
> *ity of instruction. It is the entire process of analysis of learning needs and goals and the development of a delivery system to meet those needs. It includes development of instructional materials and activities; and tryout and evaluation of all instruction and learner activities. Instructional design as a discipline is that branch of knowledge concerned with research and theory about instructional strategies and the process for developing and implementing those strategies.*

The other one is by *Suzuki* [85.9]:

> *ID refers to models and research which compile methods to improve the results, efficiency and attractiveness of educational activities as well as the process of realizing learning assistance environments which apply such models and research.*

ID design process models are generally divided into the two categories: Action, design, development, implementation, evaluation (ADDIE) models [85.10] and rapid prototyping models [85.11, 12]. Rapid prototyping models are based on ADDIE models. ADDIE models are general models for the management of ID which grasp ID activities as a process of analysis, design, development, implementation, and evaluation. As shown in Fig. 85.1 [85.7, 8], the models are based on a plan → do → check/act (see) management circle model, with the plan process subdivided into thirds. In Fig. 85.1, education/learning activities signify collaboration toward the creation of human value by each individual and the creation of social value by enterprises and the community. We address the automation of education/learning systems assuming that the ideal of education/learning systems management is to continuously create new and greater value in education/learning activities.

Table 85.1 summarizes the education/learning systems design and operational methods of each process under this model. This table is revised from models presented in *Gagne* [85.13] and *Akahori* [85.14], incorporating our own experience. We now proceed to explain ID following the processes presented in this table. (See the list of reference materials for further details.)



Improvement of social values
Knowledge creation
Active learning
Improvement of efficiency
Motivation for learning
Destruction of the status quo (Revision of the standard)
Maintenance of the status quo
Maintenance of the status quo
Maintenance of the status quo
Control (C/A)
Imple-mentation (D)
Plan (P)
Plan
Implementation

Control
Improvement of human values
Conservative learning

Fig. 85.1 Concept model for learning activity to create new values based on management circle model (after [85.7, 8], [85.8], with permission from Interscience Enterprises Ltd., 2009)

Table 85.1 Instructional design process model and its operations and methods

Management circle	ADDIE model	Operations and methods	
Plan	Analysis	Needs analysis Job analysis Student analysis	
	Design [85.15, 16]	Determination of learning goals (target behaviors, evaluation conditions, achievement levels)	
		Structuring Sequencing Programming [85.22, 23]	Determination of learning contents (knowledge, skills, values) [85.14, 17–21] Determination of learning methods considering student characteristics Determination of provision methods (joint training/individual training) × (cost performance)
	Development [85.24–27]	Textbooks Multimedia materials (in-house or consigned development) audiovisual + interactive	
Do	Implementation [85.28–35]	Tutoring Mentoring	
Check/act (see)	Evaluation	Evaluation subject	Learner Program
		Evaluation method [85.36–41]	Formative evaluations + comprehensive evaluations Reaction/learning/behavior/results

Analysis

The purpose of analysis is to extract useful information on what the parties are attempting to teach for setting learning goals. Analysis results directly affect the content of the structuring and sequencing, which are the next stages in the design process. To begin with, needs analyses are conducted to determine what instructors and learners are seeking (what they want to achieve), and to clarify the social trends, human resources development strategies, educational plans, career designs, and other assumptions, as well as the limiting conditions on the educational resources available for use. When the learners are adults, job analyses may also be conducted to identify the required competencies [85.42] from work duties content analysis. It is also necessary to conduct student analyses to clarify learners' academic history, experience, and learning preferences.

Design Process

Most of the debates regarding ID largely focus on the design process, with two different system approaches to ID. The Reigeluth approach [85.15] divides system design factors into three categories:

1. Learning conditions (learning issues, student characteristics, learning environment, etc.)
2. Learning methods (learning contents compilation methods, implementation methods, evaluation improvement methods, etc.)
3. Learning results (results, efficiency attractiveness, etc.).

Then, the combinations of the categories are classified into descriptive theory and prescriptive theory depending on what are cause factors and effects factors. The Rickey approach [85.16] combines an inductive approach with a deductive approach by experts, with interesting discussions of conceptual versus procedural models.

In the design process, the learning goals clarified by analysis are subdivided to the level at which they can be measured, followed by the step of structuring, which structures the relative priorities among the subdivided goals, and sequencing, which determines the learning order and contents to achieve the goals considering learner characteristics and improvement of education results and efficiency. Refer to *Gagne* [85.17], *Reigeluth* [85.18, 19], *Merrill* [85.20], *Sato* [85.21], and *Akahori* [85.14] for detailed discussions of these issues. Models and methodologies adopting their research findings provide an extremely valuable framework for the fusion of education/learning activities with information technology.

Educational programs are then compiled, considering the learning goals, learning content, and learning formats (group or individual), and synchronous or asynchronous learning as well as the limitations on time and educational resources. Some examples of the learning formats are shown in Fig. 85.2 in which formats are classified into distance learning [85.44] or not, and self-directed learning or not.

ID research is also being advanced by *Keller* [85.22] and *Suzuki* [85.23] on the attention, relevance, confidence, satisfaction (ARCS) model as a means of motivating learners by creating more attractive education and learning environments.

Development

Development sets the educational units via the following considerations on the series of learning goals and learning contents generated by the design works [85.13]:

1. Selection of learning goals
2. Listing of instructional events
3. Selection and development of educational materials and learning activities
4. Division of rules between instructors and learners.

Among these, the core task is the selection and development of educational materials, for which the potential applications of ICT and other multimedia and digital technologies have been greatly increasing in recent years. Prior to the arrival of this new era, *Gagne* [85.13] recognized and made an interesting suggestion that computers and other new media are significant for education not just because they enable stimulating presentations as instructional events but because they are important factors for improving learning results, effectiveness, and attractiveness.

Active learning [85.24] has also been gaining attention as a new trend in educational methodology development, primarily in the business world. The case study, scenario, and simulation methods are representative examples of active learning, and these include the goal-based scenario (GBS) theory advocated by *Shank* [85.26] for the scenario methods. GBS is an ID

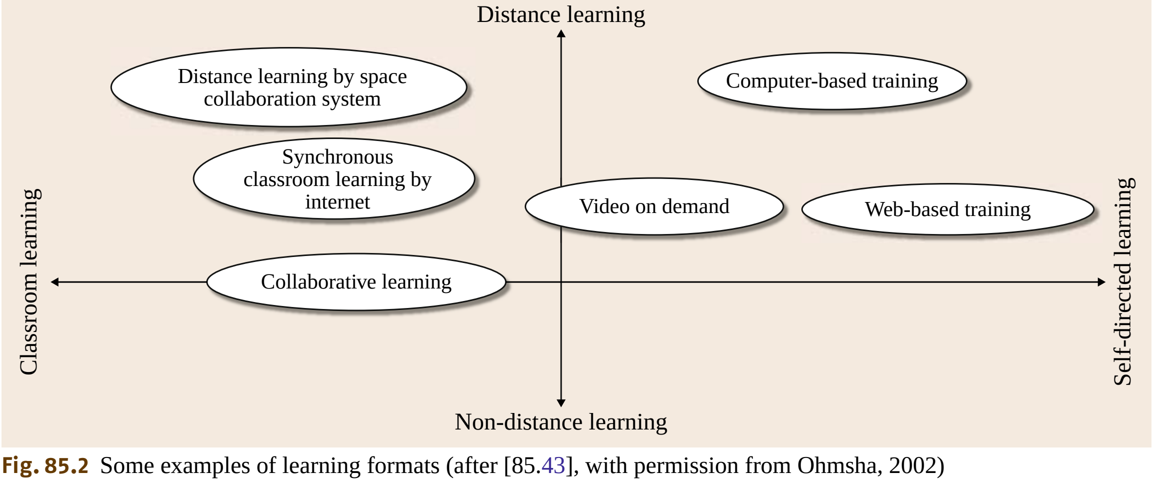

Fig. 85.2 Some examples of learning formats (after [85.43], with permission from Ohmsha, 2002)

theory for developing scenarios as a learning environment to provide students with vicarious experience of learning from failure, using actual cases from business literature [85.27, 28].

Implementation

Various communication channels are formed by the student learning environment at this stage, where the designed instructional content is implemented. The challenge for these channels is to realize system design and operation that holds and increases the learner's interest. From a learner-centered perspective, the channel formation factors include the human factors of instructors, mentors, tutors, other learners, and educational materials distributors and the material factors of computers, media displays, and educational materials distribution systems. The materials factors mostly concern the design of the man–machine interface.

However as the learning activities themselves are fundamentally human activities, the issue of the automation of education/learning activities assuming an advanced information society brings us to reconsider the definition of what constitutes a human being. In that sense, such questions as instructor competency [85.28] and presence [85.29–31], how to make learners actively involved with instruction administration [85.32, 33], and psychological aspects [85.34, 35] will be important issues for future examinations on the automation of education/learning activities.

Evaluation

Kirkpatrick [85.36] provides a typical four-stage ID evaluation model. This model divides evaluation of the development and implementation of education/learning systems into the four levels of reaction, learning, behavior, and results. It clarifies the evaluation period and evaluation items, as well as the data collection, measurement, and evaluation methods. This model gives consideration to e-Learning, for example, in the handling of return on investment, which is a level 4 results evaluation item [85.37, 38]. Formative or comprehensive evaluation methods may also be used, depending upon the evaluation objective [85.39]. Comprehensive evaluations provide an overall evaluation of the learning effect after a series of learning activities is completed. Formative evaluations [85.40, 41] are evaluations conducted during the learning process for the purpose of improving the education and learning activities.

85.1.2 Development History and Present Conditions of e-Learning

In this section we address e-Learning as an education/learning systems automation topic, and review the peripheral technologies, development history, and present conditions of e-Learning.

Definitions of e-Learning

Definitions of e-Learning are extremely diverse, and have changed over time. Sample definitions include the following:

- American Society for Training and Development (ASTD) [85.45]:

  e-Learning refers to all items provided, facilitated or transmitted by electronic technology that are clearly for the purpose of learning.

- *Broadbent* [85.46]:

  Computerization is important for e-Learning. e-Learning means computerized training, education, coaching, and information, and includes synchronous and asynchronous learning that is assisted by technologies such as the internet, CD-ROMs, satellites, telephones, personal computers, PDAs and other wireless equipment, multimedia, and CBT.

- *Rosenberg* [85.47]:

  e-Learning refers to the provision of diverse solutions using internet technologies to heighten knowledge and performance.

- The Japan e-Learning consortium (JeLC) [85.48]:

  e-Learning is independent learning using information technologies and communications networks. The contents are arranged in line with the learning goals, and interactivity is secured as necessary between the learner and the contents provider. This interactivity gives the learner opportunities to participate at will, so appropriate instruction can be given at appropriate times while advancing learning through people and computers.

e-Learning Peripheral Technologies

Because e-Learning is based on information and communications technology, it encompasses diverse learning formats which can be categorized by the following distinctive characteristics:

1. Educational materials and their distribution methods
2. Communication between instructors and learners.

In characterizing (1), the extent to which the learning is electronic can be measured by the computerization of the contents and distribution. e-Learning where the contents used as educational materials are more computerized and the distribution involves less human intervention is considered to be more electronic.

In characterizing (2), Fig. 85.3 positions e-Learning with greater potential for two-way communications as having a higher level for interactivity. This figure was prepared by the Japan e-Learning Consortium (JeLC) [85.48], and partially revised by the authors. The items marked by solid circles denote those characterized as e-Learning. Videos are considered a borderline area because of the existence of both digital and analog videos. From this figure, we project that the development of future e-Learning technologies will move toward higher levels of computerization and interactivity under lower cost.

The History of Problem Solving and Value Creation in the Development of Computer-Assisted Education/Learning Systems

Reviewing prior efforts to use computers in education/learning systems, the fusion of problem-solving needs at learning and education sites with the seeds of instructional design theory can be recorded as the history of advancing automation using computer and communications technologies. Table 85.2 presents the history of problem solving from computer-assisted (aided) instruction (CAI) through to e-Learning, explaining the problems, solutions, and main technologies involved. Table 85.2 compares e-Learning with CAI, CBT, and web-based training (WBT), but the e-Learning system involves CAI, CBT and WBT as a whole as shown in Fig. 85.2 and its definitions.

Among the various e-Learning stakeholders, Table 85.3 examines the learner, instructor, and training

Table 85.2 History of problem solving in computer-assisted education/learning systems ([a] The use of PDAs and cell phones is included)

Name	Problems to be solved	Solution	Automation elements
CAI: computer-assisted (aided) instruction	Money and time are required for the following items using conventional systems: • Instructors and learners must be at the same location for long periods of time • Learners' progress and other items must be compiled manually	Display learning contents in accordance with the level of understanding of each learner, and save money and time via computer assistance	Computer
CBT: computer-based training	Learning order is determined beforehand by manuals in CAI, so learners cannot freely choose learning order	Educational materials compiled into a database, allowing interactive setting of learning order	CD-ROM Personal computer
WBT: web-based training	CBT has the following problems: • Unified management of learners' progress not possible • Educational materials cost money • Educational materials changes and improvements are difficult	Educational materials are transmitted via networks, facilitating quick revisions and learning evaluation Materials can be used for both synchronous and asynchronous learning	Internet-WWW
e-Learning	WBT has the difficulty of compiling optimal learning plans from the perspectives of results, efficiency, and attractiveness considering learners' academic history and progress, etc.	Learners can study independently, making maximum use of the potential of information and communications technologies to meet individual learning needs	LMS, m-Learning [a]

manager and identifies the value creation in terms of cost, time, and quality.

e-Learning Platforms and Standards

The platforms and standards for e-Learning systems are another technical aspect which supports e-Learning. The development and spread of these technologies have facilitated the low-cost development of e-Learning systems with consistent quality, and greatly contributed to the spread of e-Learning. The spread of e-Learning systems also advances the further development and evolution of e-Learning systems.

Table 85.4 summarizes the platforms and standards for learning management systems (LMS) [85.49], which constitute the core of e-Learning systems. LMS are platforms which provide such functions as educational materials management, learning progress management, learning implementation phase management such as management of mentoring and tutoring, and testing phase support for question setting, grading, performance results processing, and contents creation.

Learning contents management systems (LCMS) are primarily platforms to support educational mater-

Table 85.3 Value creation by e-Learning

Value/ stakeholder	Learner	Instructor	Training manager
Cost reduction	Educational materials receipt expenses	Educational materials distribution expenses	Indirect cost
Time efficiency	Faster acquisition of materials and learning results	Faster learning results feedback	Faster system performance management
Quality improvement	Permits acquisition of the most recent educational materials Permits repeated study (review) Allows control over learning pace	Permits preparation of the most recent educational materials Accumulation of study history data Uniform distribution of the same educational materials	Accumulation of study history data

ials developers. These platforms offer the two functions of authoring, which are the compilation and production of educational materials, and educational materials database management.

The sharable content object reference model (SCORM) in the "standards/tools" column is a web-based training (WBT) standard that integrates computer-managed instruction (CMI) with the learning object metadata/learning object reference model (LOM) standards, which are learning resource data structure standards. The LOM standards are used to describe the attributes of learning objects, which comprise all resources used in learning.

The learning information package (LIP) standards are used to describe the attributes of learners. The question and test interoperability (QTI) standards cover the necessary information for implementing tests. Single sign-on (SSO) is an e-Learning system technology which allows learners to log in once and gain access to library information systems, academic affairs management systems, and various other existing systems and resources aside from the LMS.

In 2005 the Organization for Economic Cooperation and Development (OECD) conducted a survey among institutions of higher education worldwide [85.59] regarding the conditions of e-Learning. Respondents noted the difficulty of assuring the quality of e-Learning [85.60], along with various other issues such as difficulty using present technologies [85.61], and problems with creating, selecting, and using learning objects [85.57]. Considering these evaluations, the present platforms and standards technologies are immature, but should serve as the basis for future development. Research projects on developing architecture to break down LMS components into modules and restructure the LMS e-Learning architecture in accordance with work flow include the MIT Open Knowledge Initiative [85.58] and the e-Framework [85.62] being jointly developed by the UK and Australia. The other projects for e-Learning in USA and Europe may be found at [85.63–67].

e-Learning may be classified into synchronous and asynchronous learning. In asynchronous learning, learners communicate individually with computer systems such as WBT. In synchronous learning, multiple learners communicate among themselves or one or more learners communicate with a tutor or mentor under a computer-supported collaborative learning (CSCL) environment. Synchronous learning is similar to small-group *kaizen* (continuous improvement) activities in Japan. The platforms for collaborative e-Learning are still being established. CSCL is defined by *Koschmann* [85.68] as a field of study centrally concerned with meaning and the practices of meaning-making in the context of joint activity, and the ways in which these practices are mediated through designed artifacts. Interested readers should refer for details to [85.50–56].

85.2 Examples

This section introduces two examples of the development of education/learning systems in Japan based on *kaizen* (continuous improvement) knowhow in the Japanese manufacturing industry [85.69–72]. One is a program for understanding the mechanism of engineering and management of issues according to the general product lifecycle process of the manufacturing industry such as new product design, production system engineering, production planning, production management, supply chain management, production information management, and project management. The other is a program for managers in leadership roles who are contributing to creating new business value in manufacturing technology. The both programs have resulted from development of learning contents and numerical simulation software from effective utilization of e-Learning. The basic concept behind the both program developed has an effective combination with an intelligent knowledge-based approach [85.73] with the *kaizen* activity through problem-based learning (PBL), case method learning (CML), and computer-supported collaborative learning (CSCL) as well as *blended learning* combining lectures with practice.

85.2.1 Educational Programs for *Cyber Manufacturing* in Industrial Engineering and Information Management

Overview of the *Cyber Manufacturing* Program

The Research Center for e-Learning Professional Competency (eLPCO) in the Research Institute of Aoyama Gakuin University in Japan has been organizing joint research projects between higher education institutions and industrial corporations. A research working group

Fig. 85.4 Learning map for each course unit composed of *cyber manufacturing* core curricula

for *cyber manufacturing* has been promoted by ten universities and several manufactures and software vendors as a series of eLPCO project activities. The main objective of this working group is to develop practical core curricula in the *industrial engineering and information management* field by efficiently using e-Learning methods [85.74].

As illustrated in Fig. 85.4, four course units on engineering processes and four course units on operational management processes have been developed as the total educational program for *cyber manufacturing* [85.75]. The characteristics of e-Learning methods for each course are to integrate the *blended-learning* style between lectures and practices supported by a learning management system (LMS) and simulation software. Additional characteristics are treated with various instructional strategies such as *case method learning* (CML), *problem-based learning* (PBL), and *computer-supported collaborative learning* (CSCL).

The CML method assisted with three-dimensional computer graphic (3-D-CG) simulation refers to a learning method based on a case study in a virtual experience model of the real world. Thus, by utilizing 3-D-CG simulations as shown in left arrows of Fig. 85.4, practices involving observation and process analysis of product

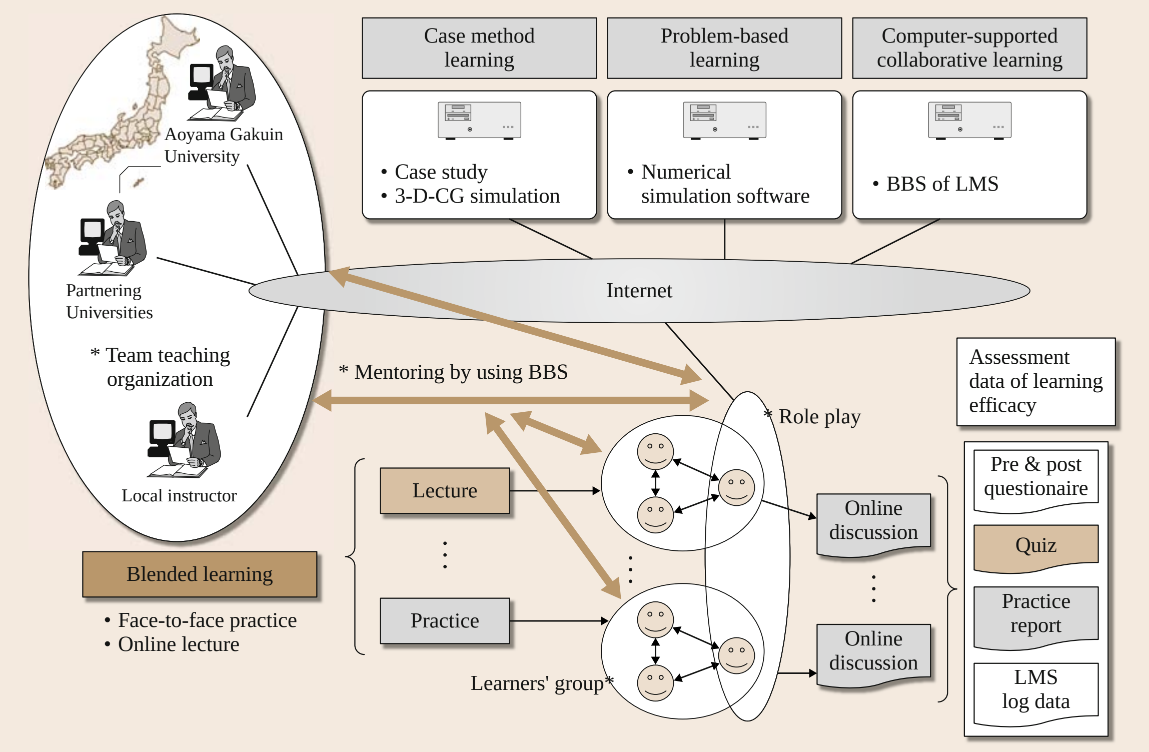

Fig. 85.5 Instructional strategy of *comprehensive learning style* combined with PBL, CML, and CSCL

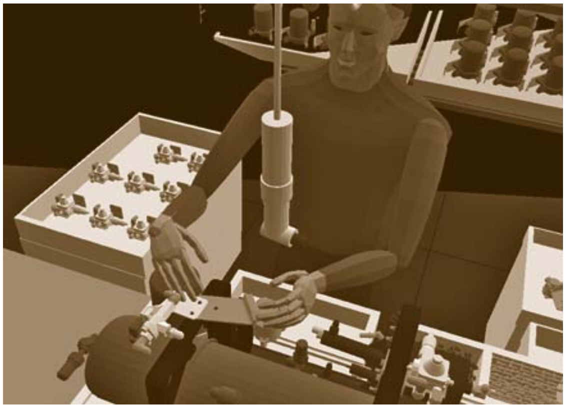

Fig. 85.6 Work analysis in practice of *design of work system* course unit, using task observation of moving images of 3-D-CD human task simulation modeling

design activities and production system methods in virtual factories are implemented. Some examples of the utilization of 3-D-CG simulation in the practices include a 3-D-CG digital mock-up simulator (virtual trial manufacturing) in the *product design and process engineering* course unit, a 3-D-CG production line simulator in the *layout and material handling* and *design for production system* course units, and a 3-D-CG human work simulator (Fig. 85.6) in the *design for work system* course unit.

The aim of our PBL method is for learners to acquire practical skills through practice by using numerical simulation software. The software to support numerical simulation and data processing is developed by university–industry cooperation. After finishing the theory lecture, practice is conducted by using the numerical simulation software. Several practice problems are prepared and the learners are encouraged to solve the problems with suitable application of the learned theories, to create more desirable solution alternatives.

An LMS is a set of software tools designed to manage user learning interventions, courses, instruction, content delivering, online communication, assessment/testing, and so on. Most LMSs are web-based to facilitate *any time, any place, any pace* access to learning content and administration. The online learning environment used by universities allows instructors to manage their course and exchange information and opinions with learners for a course that in most cases will last several weeks and will meet several times during those weeks. Note that basically all the lectures and practices in the course units utilize original LMS, developed by eLPCO under industry–university cooperation.

New Instructional Strategy of Comprehensive Learning Style and Uniqueness of Lectures and Practices

As illustrated in Fig. 85.5, in order to conduct the practice corresponding to each lecture, a new instructional strategy of *comprehensive learning style* is applied in each of the course units. This is developed by combining especially three types of instructional strategies: case method learning (CML), problem-solving learning (PBL), and computer-supported collaborative learning (CSCL).

In all the course units, the aim of the lectures is to understand the theoretical knowledge relating to engineering and management processes, while the object of the practices corresponding to each of the lectures is to acquire practical skills by using 3-D-CG simulation, numerical simulation software, and a asynchronous bulletin-board system (BBS) communication function, through various instruction strategies combined with CML, PBL, and CSCL.

The reason behind the creation of this new instructional strategy is to achieve deeper knowledge, while attaining practical skill, in the *industrial engineering and information management* field, because the conventional lecture method alone is not enough for rudimentary learners to understand complicated engineering and management processes.

Therefore, the creation of virtual images modeled by 3-D-CG simulation, and the development of new numerical simulation software in accordance with the content of the practices for each of the course units, are implemented. This has resulted in the preparation of a *practice learning environment*, which is said to be one of the most difficult environments with practical learning to take the *comprehensive learning style* class in e-Learning.

Furthermore, the characteristics of designing and operating method of the class style, by *blended learning* increase the difficulty, in which learn-by-doing instruction activities are realized by repetitive combination of the lectures and practices.

The goal of blended learning is to synthesize learning media into an integrated mix, which can be tailored to create a high-impact, efficient, and exciting learning program. The term *blended learning* is defined as [85.76]:

Blended learning is the combination of different training media (technologies, activities, and types of events) to create an optimum training program for a specific audience. The term blended means that traditional instructor-led training is being supplemented with other electronic formats. In the context, blended learning programs use many different forms of e-Learning, perhaps complemented with instructor-led training and other live formats.

Case Method Learning (CML) Assisted With Three-Dimensional Computer Graphic (3-D-CG) Simulation

It is not an easy issue to educate learners who are not able to imagine real field manufacturing and operational management at the product design and production phases, in course units related to engineering and management processes. In particular, new learners may not be able to understand easily the working environment, sequences of part assembling, and human task processes in manufacturing factories.

Thus to make the practices based on CML more effective, some special features are added to enrich the practice learning environment. These features include illustrations of production procedure modeling and realistic depictions and task analysis of virtual manufacturing based on animations created using multiple 3-D-CG simulators. As illustrated in Fig. 85.6, learners can visibly understand and analyze virtual human task processes in an assembling production line, which are expressed as moving images modeled by using a *human task simulator*.

Fig. 85.7 Group practice using numerical simulation software for PBL and 3D-CG simulation image of a virtual factory for CML

Problem-Based Learning (PBL) by Using Numerical Simulation Software

Problem-solving ability is the ability to combine previously leaned principles, procedures, declarative knowledge, and cognitive strategies in a unique way within a domain of content to solve previously unencountered problems [85.77]. This activity yields new learning as learners are more able to respond to problems of a similar class in the future. This type of problem solving is often described as *domain-specific* or *semantically rich* problem solving because it emphasizes learning to utilize principles in a specific content area.

Figure 85.7 shows a group practice study with numerical simulation software and a 3-D-CG simulation image of a virtual factory. The learner on the right is observing and measuring human operating time based on moving images from the 3-D-CD human task simulation modeling illustrated in Fig. 85.6. The learner on the left is analyzing and determining standard time in a practice from the *design of work system* course unit, using the numerical simulation software.

The numerical simulation function as practical operation could support learners in understanding the application method of techniques learned by a lecture. In addition, learners can carry out individual steps involved in the practice under the guidance of instructions on each screen of the numerical simulation software. So the learner will be able to discover the characteristics of the appropriate application method of the theories and techniques by altering various parameters. The software is also equipped with a function that automatically processes practice data and illustrates summation tables and analysis graphs.

Computer-Supported Collaborative Learning (CSCL)

The last type, CSCL, is an instructional approach in which learners of varying abilities and interests work together in small groups to solve a problem, complete a project or achieve a common goal [85.78]. In each of the practices, learners, who are each given a role as shown in Fig. 85.5, are able to express their opinion and engage in mutual communication using an asynchronous bulletin-board system (BBS), installed in the learning management system (LMS).

One advantage of the e-Learning environment is its ability to create a kind of BBS function in the LMS to allow learner interaction. It is possible that one learner finds a good way to understand the theory applications learned through the lecture and practice, or learners want to compare the problem solution results that they

Table 85.5 The curriculum on production planning (MRP) system

Influencing factors on master production scheduling (MPS): **(a)** Cost parameters **(b)** Lead time **(c)** Changes in demand	Lot-sizing rules: **(a)** Lot-for-lot rule **(b)** Economic order quantity rule **(c)** Period order quantity rule **(d)** Minimum cost planning rule	Overall MRP system execution: **(a)** Creating production plan based on MPS **(b)** Based on the production plan, create MRP plan for all parts **(c)** Minimizing the costs

have achieved in the practice. In this case, through online discussion, learners can submit their comment, tips, and/or questions to the BBS, allowing other learners to view them. Therefore, a more communicative lesson is enable, while at the same time maintaining personal (not group) learning to avoid dependency on the learning environment.

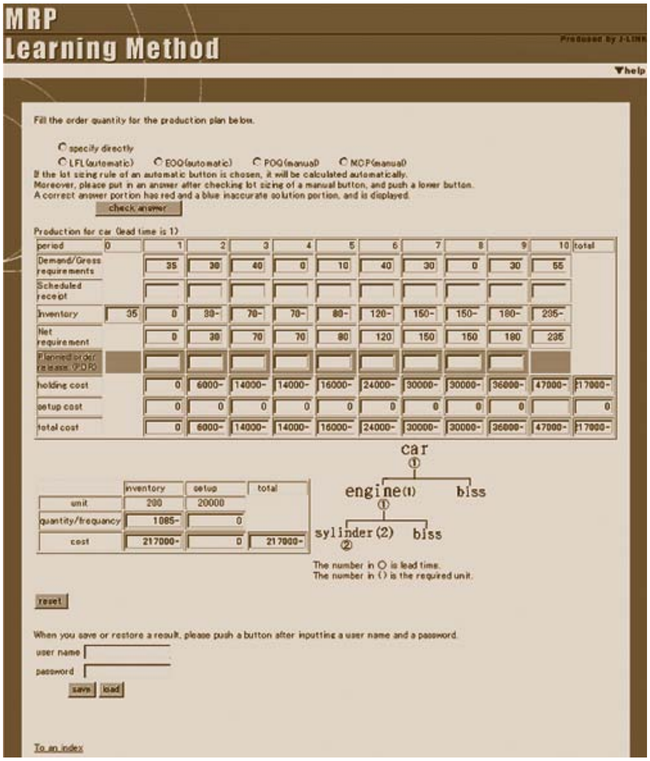
Example of Learning Contents of Material Requirements Planning (MRP) in the *System* Course Unit

An example of new numerical simulation software to support *problem-solving learning* e-Learning, within *material requirements planning* (MRP) in the *system* course unit is introduced in this section. The PBL e-Learning method utilizes an established local-area network system to allow learners to access directly the numerical simulation software through the LMS during the course. The introduced software is specifically design to support the MRP system course. The software is intended to reduce the calculation effort, allow learners to switch their effort in generating a more efficient production plan, and improve their interest in the subject. The final objective is to improve the knowledge and skill attained during the course that uses the new learning method.

Overview of the Material Requirements Planning (MRP) Course Unit. Material requirements planning (MRP) systems, a technique in production planning and inventory control system [85.79, 80], are widely used in companies nowadays. Practical education programs in production planning (e.g., MRP system) are expected by companies from new workers. In order to answer this demand, in a series of *cyber manufacturing* programs in the *industrial engineering and information management* field, learners are required to understand MRP system, along with other techniques such as inventory planning, project management techniques, and manufacturing resources planning. Generally, the objectives of this course unit are to develop the necessary knowledge and ability to design a reasonable production planning, by taking all necessary factors into consideration.

The curriculum for e-Learning method on MRP system proposed here is shown in Table 85.5 [85.81]. The MRP course unit requires three learning lessons. Each lesson consists of 90 min lesson time, during which instructors describe the required theories, and 90 min practice time, during which the learners have to accomplish the practice prepared beforehand using the numerical simulation software to help them. The main objective of this e-Learning method is to improve the knowledge and skill attained during the course. Accordingly, the software is also prepared to have three separate practice problems, each corresponding to one lesson.

Master Production Schedule (MPS) Planning and Lot Sizing Rules. In the second lesson, MPS planning for the final item is allocated ten periods, as shown in Fig. 85.8. Here, the learners can choose whether to enter the order quantity directly, or to use one of the available lot-sizing rules, as illustrated in the upper part in Fig. 85.8. If the learners choose to complete the order quantity directly, the software will automatically conduct other calculations such as on hand inventory, total setup costs, total holding costs, and total costs. On the other hand, the software will automatically calculate all required values if the learner chooses one of the lot-sizing rules.



Fill the order quantity for the production plan below.

○ specify directly
○ LFL(automatic) ○ EOQ(automatic) ○ POQ(manual) ○ MCP(manual)
If the lot sizing rule of an automatic button is chosen, it will be calculated automatically.
Moreover, please put in an answer after checking lot sizing of a manual button, and push a lower button.
A correct answer portion has red and a blue inaccurate solution portion, and is displayed.

Fig. 85.8 Image of the software used in the *MRP systems* course unit

The objectives of this second practice are to familiarize the learners with the MPS logic and lot-sizing rules, to realize trade-off relations between lot-sizing rules, to realize trade-off relations between holding and setup costs, and to prepare the user for more complicated MRP in practice 3.

Assessment Method for Learning Efficacy

Stated below are the measures used to collect data of learning efficacy. Data would be assessed in order to guarantee the quality of the lectures (previously shown in Fig. 85.5, *assessment data of learning efficacy*):

1. Measuring the level of understanding (knowledge level) of the lectures based on the result of a quiz
2. Measuring the level of skill acquisition (skill level) from the practices based on the results of a report for each course unit
3. Evaluation of the effectiveness of the course and the software through data analysis of a previous questionnaire at the beginning of the course, a questionnaire for each course unit, and a final questionnaire at the end of the whole course (the questionnaire would be open-ended and multiple choice)
4. Logging of data analysis related to the learning record in the LMS, such as grade data, BBS discussion records, etc.

The quiz at the end of the theories taught in lectures should evaluate learners' understanding. The quiz is of multiple-choice type, so submission and appraisal of the quiz could be implemented automatically, using the advantage of the LMS.

The report worksheets are beforehand with each practical training, and the LMS distributes them. The learners make their reports by using software of the system, and have to submit the worksheet to the instructor by the LMS before the next start time of lesson. The admission report is conducted automatically by the LMS.

Table 85.6 Course objectives and student goals

Course name	Course objectives	Intended learning outcomes
Quality management (QM)	Acquire the ability to perform quality control by taking all measures necessary to ensure customer satisfaction and good quality	Incorporate customer needs into the quality management process, identify what actions must be taken to satisfy customer needs, and utilize appropriate methods to solve various problems that exist at the production site From the standpoint of *quality first*, identify what improvements must be made to ensure proper quality management and use appropriate measures to solve various problems that exist at the production site Describe quality management from the perspectives of the customer satisfaction and quality-first philosophies Play a leadership role in quality management activities that are based on customer satisfaction and quality-first philosophies
Manufacturing knowhow and creativity (MKHC)	Acquire the ability to identify and solve (ameliorate) problems that exist at the manufacturing site	Identify key issues that exist in a given workplace Identify and analyze the current status of a given workplace Capable of suggesting specific improvement measures Give a logical explanation of improvement measures to fellow workers in the workplace, or demonstrate how such improvements can be implemented to persuade workers to take action Capable of applying the above-mentioned knowhow in any workplace
Knowledge chain management (KCM)	Have a clear understanding of the processes involved in creating products that meet customer needs and acquire the ability to standardize and improve these processes while taking into consideration the cost and delivery time	Capable of achieving standardization and improvement in design control Capable of achieving standardization and improvement in process control Capable of achieving standardization and improvement in purchasing and subcontract management Capable of achieving standardization and improvement in cost management Capable of suggesting how standardization and improvement can be achieved in the above-mentioned management activities from the perspective of profit control

Type of questionnaire/ purpose, respondents, and timing of surveys	Precourse survey	Postsession survey	Course completion survey	Survey for the satisfaction in hosting practical sessions	Survey for the participants' supervisors
Purpose	To understand the working environment and the academic background of the participants	To understand what aspects of the course sessions need to be improved and to track the participants' progress and understanding of the course content	To assess the participants' satisfaction with with the course and to identify what needs to be improved	To assess the hosts' satisfaction with the outcomes of the improvement measures	To assess the following changes in the course participants as perceived by participants' supervisors: • Change in performance • Change in behavior • Change in enthusiasm and commitment to fulfill responsibilities
Respondents	Course participants	Course participants	Course participants	Companies hosting the practical training sessions	Superiors of the course participants
Timing	Before the start of the first session	At the end of each session	Upon completion of the course	Some time after the completion of the course	Some time after the completion of the course

85.2.2 The Case of an Educational Program for Manufacturing Managers Using IT Jigs

Program Objectives

The aim of this educational program [85.7] is to provide participants with the knowledge and skills required to manage manufacturing processes employed by small to medium-sized manufacturers of industrial machinery in the Hokuriku District of Japan. Classroom instruction practical exercises will cover the following:

1. Made-to-order manufacturing and flexible manufacturing systems, both of which are implemented widely by manufacturing companies in the Hokuriku District to control quality, cost, and lead time
2. Total optimization (instead of partial optimization) of all production processes
3. Continuous improvement in the workplace.

Based on these learning goals, three courses and their course objectives were developed, as shown by Table 85.6.

Program Evaluation Method

Based on *Kirkpatrick*'s model [85.36], the evaluation method shown in Table 85.7 was developed and implemented by a web system. The method consisted of five kinds of questionnaires for three kinds of stakeholders (participant, companies hosting the practical training sessions, and participants' supervisors) to evaluate the program. This system can highlight many useful issues for continuously improving the program.

A Circuit Model for Instructional Design

Figure 85.9 shows a flowchart called a circuit model [85.82], which represents the way in which the educational program is implemented. Practical exercises are designed to nurture each participant's ability to implement *kaizen* and are thus focused on the problem-solving process. Many of the conventional approaches to problem solving may not be effective in actual work settings; in fact, problem solving and *kaizen* are often complicated processes that involve the use of many unconventional approaches. As shown in Fig. 85.9, the learning cycle for the educational program consists of three processes: learning through ing through seminars, and creating knowledge through practical exercises. The participants in the program may use conventional individual and group approaches. As they use unconventional approaches in a workplace setting, however, they will begin to understand the limitations of conventional approaches. The first two processes are learning and understanding; the third is creating. The above learning cycle is repeated several times (one learning cycle per subtheme) during the course of the program. When the participants complete the program, they repeat the learning cycle once again to assess their understanding.

The Development of IT Jigs

As a successful case of instructional development for the *knowledge chain management* (KCM) course, IT educational tools (IT jigs) were designed to help individuals involved in production planning process. This approach uses three types of bills of materials, three master files, a layout editor, a loading analyzer, and a flexible manufacturing system [85.83] (FMS) simulator. IT jigs are also highly effective tools for acquiring practical knowhow on decision-making procedures in

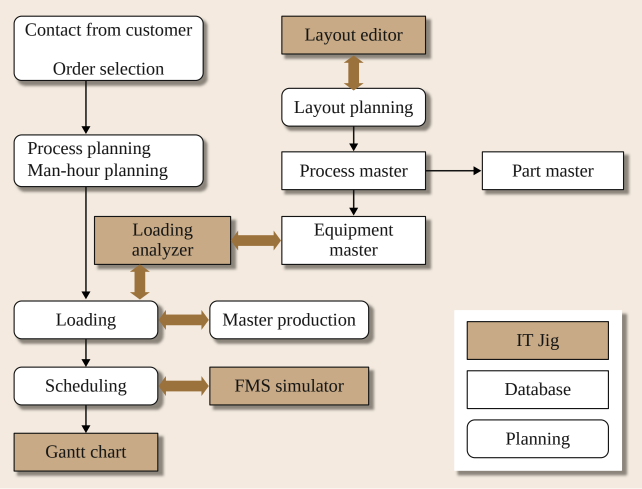

Fig. 85.10 IT educational tool (IT jig) for production planning and control

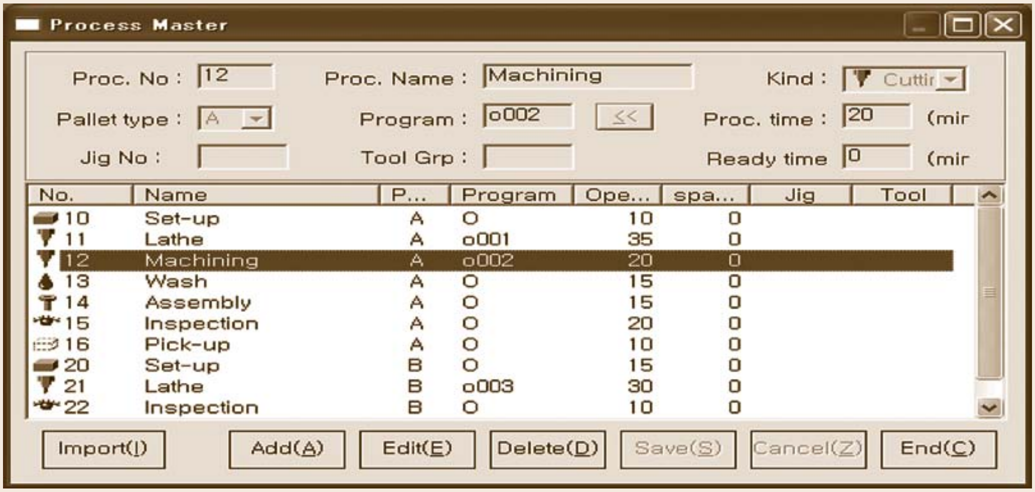
process control activities, which can be used to establish schedules and/or layout plans. These tools require no special programming skills to use, and are easily operated through the simple manipulation of icons.

Production Planning and IT Jigs Procedures. Process control should be designed so as to enable effective management of manufacturing processes and to maximize customer value creation. Effective processing of order information is key to achieving this. The relationship between order information and process control is summarized in Fig. 85.10, which depicts a series of activities starting from the contact from the customer to scheduling. Any uncertainties and/or nonconformity in the process should be identified, which should then be corrected, improved, and standardized in a timely manner so as to ensure continuous improvement of process control techniques. The roles of the layout editor and FMS simulator [85.84], which are the IT educational tools (IT jigs) designed to help individuals in the described planning process, are summarized in Fig. 85.10.

Creating the Process Master. The process master in Fig. 85.11 is created by determining the types (installation, cutting, cleaning, etc.) and number of processes to be handled by the processing facilities (machining centers (M/Cs), lathes, inspection machines, etc.), and by inputting a series of process information (1–7 below) and the processing procedures. Appropriate machines and equipment should be selected beforehand for the processing facilities using Layout Editor. Process information series 1–5 are identified during process planning and process information series 6 and 7 are identified during man-hour planning:

1. Process number: assigned to each process. The same number should not be used twice. The process number is equivalent to a process address.
2. Process name: a description of the specific process, e.g., injection, drilling, threading, etc., or process 1, process 2, etc.



Proc. No : 12　Proc. Name : Machining　Kind : Cuttir

Fig. 85.11 Example process master screen

3. Process type: there are six categories, namely installation, cutting, cleaning, assembly, inspection, and removal. For more details, refer to the description provided later in the chapter.
4. Palette type: a tool that resembles a tray, which is used to transfer work pieces to each process.
5. Program: numerically controlled machine tools (NC machine tools) are controlled using a processing program. This information should be entered only when the process type is cutting.
6. Processing time: the time required to handle the process, which is estimated either during the design phase or based on experience.
7. Nonprocessing time: the time required for operations that do not involve the processing of work pieces, i. e., setup or replacement of a processing program and/or preparation of the necessary equipments and materials.

An example process master screen is shown in Fig. 85.11.

Creating the Equipment Master. The equipment master shown in Fig. 85.12 is a master file that determines and allocates the appropriate equipment for performing the kinds of process selected using the process master (Fig. 85.11). In short, users can identify the load for each facility by creating an equipment master. The equipment selected using the layout editor is automatically listed in the equipment information pane shown inside the solid lined box in Fig. 85.12, and the symbol representing the process type is listed beside the selected equipment in the *ID* column, as shown inside the dotted lines. If you click on *machining* in the *equipment information* pane, all the processes for which *cutting* has been selected as the process type using process master will be listed in the *processes that can be added* pane as shown inside the dotted-line of *additional process*. From the list of processes that can be added, select the process to be allocated to *machining* (*MC01*) and then click on *add* (*allocate*). In Fig. 85.12, processes to be allocated are being selected (with four processes, designated as either *machining* or *lathe* as the available processes). Figure 85.12 shows that a total of two processes (process numbers 12 and 23) designated as *machining* have been selected for allocation.

When an item is selected from the list displayed in the *equipment information* pane, only the processes belonging to the same process type (specified using [process type] in process master) are displayed in the *processes that can be added* pane.

Creating the Parts Master. The parts master shown in Fig. 85.13 is a master file used to manage the delivery schedule for each part and product. This is accomplished using a process list created with the process master, which consists of a list of selected parts/products as well as of a series of related processes, to assign appropriate process(es) to each part/product. For example, Parts-C has the five process operations from number 30 to 34 in Fig. 85.13. Production schedules can be prepared by combining production plan with the information provided in the parts master.

The creation of the three masters described above is an important decision-making process that connects process design (ranging from procedure planning to load planning for each process) to process control. In most companies, process control knowhow accu-

Fig. 85.14 Example of a master production plan

mulated through years of experience is often neither documented in manuals nor shared through information systems. In view of this, it is important to involve operators working on site in the process of creating the three masters so as to identify and incorporate all the process control knowhow accumulated in-house.

Master Production Plan and Scheduling. Figure 85.6 presents the master production plan window showing a list of the orders received in a planning period, the items to be manufactured, and the time required for the production of each item. Production schedules are established based on this information and the three Masters. The parts name column shows a total of fore items: Parts-A (order number 01), Parts B (order number 02), Parts-C (order number 03), and Parts-D (order number 04), which are to be included in the production plan. The following information can be derived from the plan.

The *start date and time* and *finish date and time* show when production should be completed. *Start date and time* refers to the date and time when production can be initiated. Assuming that all the necessary materials are ready and available for production, *start date and time* is either one of the following:

- The date and time when the order is received, if dynamic scheduling is used
- The date and time when the plan is finalized, if periodic scheduling is used.

When there is advanced knowledge that the arrival of some of the materials will be delayed, the date and time when all the materials will arrive should be set as the date and time when production can be initiated.

Figure 85.15 provides an example of a Gantt chart created using the dispatching rule (first-in first-out, FIFO) retrieved from the FMS simulator. Besides

Fig. 85.15 Example FMS schedule Gantt chart scheduled by FIFO

FIFO, earliest due date (EDD), most work remaining (MWKR), and other dispatching rules are also available in the FMS simulator menu as well as some scheduling parameters with automated guided vehicle (AGV). Users can simulate scheduling either by using one of these dispatching rules or by creating their own unique dispatching rules as well as production/handling lot size, buffer stock size, and material handling schedule, and then assessing the simulation results. The simulator is designed to provide users with practical knowhow on scheduling, and offers useful tips on effective scheduling and process control.

85.3 Conclusions and Emerging Trends

This chapter has considered the automation of education/learning systems with an overview of the development history and present conditions of e-Learning based on instructional design, and introduced examples of manufacturing management personnel programs in management systems and industrial engineering (IE). For additional information on the automation of education see Chap. 44. In this final section, as a conclusion, we present the issues and outlook for the automation of education/learning systems, centered on e-Learning.

If education/learning systems aim at creating new social value for enterprises and communities by drawing together individual value creation activities [85.85, 86], e-Learning is one systematic approach for the use of information and communications technology in education/learning systems. Much of the development of e-Learning to date has focused on basic arrangements as an effective means to make conventional education and learning methods more efficient and convenient, and some accomplishments have been realized [85.87]. Considering the future outlook based on these achievements, e-Learning has the potential to more directly link personal value creation to social value. In other words, e-Learning can directly tie education/learning activities to the formation of business results and social capital [85.88, 89]; for example, e-Learning can go hand in hand with knowledge management, sales force management, human resources management, enterprise information portals, electronic performance support systems, and community service. The value created from such activities will mostly take the form of intellectual assets, with intellectual value, unlike the conventional material value of the past [85.90–98]. This intellectual asset formation is an effort aimed at the acquisition, understanding, and creation of explicit and tacit knowledge [85.73] that transcends the restrictions of space and time.

Given this outlook, the future development of e-Learning-related technologies will likely include the following areas:

1. Technological development issues:
   a) Development and application of user-interface technology to secure human-friendly communications such as mailing lists, bulletin boards, and machine translation
   b) Response analysis by effective tools and software such as simulation, groupware, virtual reality for analysis of natural language, numerical expressions, etc.
   c) Development and application of 3-D online virtual presentation mechanisms such as Second Life [85.99]
   d) Introduction of expert systems.
2. Man–machine systems issues:
   a) Solution for incompletion of learning management system (LMS) functions from the following points:
      - Secure and maintain learner motivation
      - Measures when there are learning deficiencies to control teaching and learning process
      - Construction of new dynamic evaluation systems
      - Open systems.
   b) Limitations of teaching methods (instructor–learner partnership, collaboration).
      Implement the following measures to develop systems where instructors and learners can jointly embody the truth that *teaching is learning*:
      - Public disclosure of good practices
      - Instructor training
      - Development of teaching methods.
   c) Cost-reduction effectiveness:
      - Resolution of intellectual property issues. Diverse e-Learning educational materials and contents are developed, produced, and administered through the hands of many stakeholders. This demands the development of systems and management technologies that protect the rights of these value creators and also enhance the convenience of learners and other users.
      - Development of social capital for e-Learning. Collaboration among application service providers (ASPs), educational institution federations, government, and the private sector to construct and upgrade social infrastructure for rational costs.
3. Nurturing the e-Learning profession.
   Development of systems to educate specialist personnel to effectively and efficiently advance the series of activities of development, design, introduction, administration, and evaluation of e-Learning systems to achieve the desired learning goals, and development of technologies to evaluate these educational systems.

86. Enterprise Integration and Interoperability

François B. Vernadat

Enterprise integration and interoperability deal with facilitating communication, cooperation, and collaboration within an organization, be it a single organization or a networked organization, or be it a public or a private organization. This chapter first defines enterprise integration and systems interoperability and presents relevant architectural frameworks. It then explains the technical, semantic, and organizational dimensions of interoperability before presenting essential standards and technology for interoperability and integration. Applications and future trends are pointed out before concluding.

Market globalization, worldwide competition, and fast changing business conditions are forcing enterprises to become more agile but also to increase communication, collaboration, and networking with suppliers, partners or distributors.

Enterprise integration and interoperability come into play any time that two or more business entities need to work together or need to share the same information. A business entity is any part of an enterprise. It can be of any size, ranging from a single workstation or an information technology (IT) system (e.g., a post in a department or an enterprise resource planning (ERP) system module) to a full organization unit made up of people, systems, different pieces of equipment, information stores, etc. In fact, it can even be any node in a supply-chain network or any component of an extended or virtual enterprise.

The need for enterprise integration, and for underlying systems interoperability, results from the increasing need to interconnect and seamlessly operate technical, social, and information systems of geographically dispersed enterprises or of different enterprises working together. This concerns the internal business processes and services of a given enterprise as well as cross-organizational business processes spanning partner companies or networks of enterprises.

The challenge of integrating enterprise systems or business entities comes from the large number and high heterogeneity of enterprise components that are subject to be interconnected. When two systems have to *talk* to each other or interoperate, they have to agree on common message formats, transfer protocols, shared (data) semantics, security and identification aspects, etc. For instance, if a bank and an insurance company want to jointly offer real-estate loans with life insurance, they have to align their customer data files, agree on loan acceptance conditions and rules, and coordinate respective local services (loan request processing, loan approval/refusal, insurance condition setting, etc.) into a common business process to offer a composite service.

In this chapter, both enterprise integration and interoperability are defined, respective architectural frameworks are presented and the underlying technologies are discussed from a three-level perspective (technical, application/semantic, and organizational dimensions). Finally, future trends are discussed before concluding.

86.1 Definitions and Background

Enterprise integration and systems interoperability aim at facilitating communication, cooperation, and collaboration between business entities. While enterprise integration has a strong organizational dimension, interoperability is more of a technical nature.

86.1.1 Enterprise Integration

Enterprise integration (EI) occurs when there is a need to remove organizational barriers and/or improving interactions among people, systems, applications, departments, and companies (especially in terms of material flows, information/decision flows, and control or work flows) [86.1, 2]. The goal is to create synergy, i. e., the integrated system offers more capability than the sum of its components.

The complexity of EI relies on the fact that enterprises typically comprise hundreds, if not thousands, of applications (be they packaged solutions, custom-built or legacy systems), some of them being remotely located and support an even larger number of business processes. This environment gets even more complicated as companies these days are increasingly involved in merger, fusion, acquisition, divestiture, and partnership opportunities.

Fig. 86.1 Enterprise integration levels and related technologies (essential technical terms and acronyms appearing in the figure are explained in Sect. 86.3 of this chapter and more information on each of them can be found at http://whatis.techtarget.com) (FTP – file transfer protocol, ISO-OSI – International Standards Organization Open System Interconnection, ATM – asynchronous transfer mode, J2EE – Java to Enterprise Edition, ASI – actuator sensor interface)

Integration of enterprise activities has long been, and often still is, considered as a pure IT problem. While it is true that at the end of the day the prime challenge of EI is to provide the right information to the right place at the right time, business integration needs must drive information system integration and not vice versa. EI therefore has a strong organizational dimension, in addition to its control/management dimension and its technological dimension.

From a pure IT standpoint, EI mostly means connecting computer systems and IT applications to support business process operations [86.3,4]. It involves technologies such as enterprise portals, data replication, shared business functions with remote method invocation, enterprise service buses, distributed business processes (or workflow systems), and business-to-business (B2B) integration.

From an organizational standpoint, EI is concerned with facilitating information, control, and material flows across organization boundaries by connecting all the necessary functions and heterogeneous functional entities (e.g., information systems, devices, applications, and people) in order to improve communication (data and information exchanges at system level), cooperation (interoperation at application level), and coordination or collaboration (timely orchestration of process steps at business level) within this enterprise so that it behaves as an integrated whole (Fig. 86.1) [86.1, 5]. It will therefore enhance overall productivity, flexibility, and capacity for the management of change (i. e., agility). *Li* and *Williams* [86.6] provide a broader definition of EI stating that enterprise integration is the coordination of all elements including business, processes, people, and technology of the enterprise(s) working together in order to achieve the optimal fulfillment of the business mission of that enterprise(s) as defined by the management.

Enterprise integration can apply vertically or horizontally within any organization. Vertical integration refers to integration of a line of business from its top management down to its tactical planning and operational levels (i. e., along the control structure). Horizontal integration refers to integration of the various domains (i. e., business areas) of the enterprise or with its partners and market environment (i. e., along the supply/consumer chain structure).

Integration can range from loosely coupled to tightly coupled and further to full system integration. Full integration means that component systems are no longer distinguishable in the whole integrated system. Tightly coupled integration means that components are still distinguishable in the whole but any modification to one of them may have direct impact on others. Loosely coupled integration means that component systems continue to exist on their own but can also work as components of the integrated system.

Putting in place interoperable enterprise systems is essential to achieve enterprise integration with the level of flexibility and agility required by public or private organizations to cope with the need for frequent organizational changes.

As indicated by Fig. 86.1, reaching the successive levels of integration requires building on a number of standards, languages, and technologies. Standardization efforts have been reviewed by *Chen* and *Vernadat* in [86.7] (Sect. 86.3).

86.1.2 Systems Interoperability

Interoperability is defined in the Webster dictionary as "the ability of a system to use parts of another system". In IT terms, it can be defined as the ability of two or more information systems and of business processes they support to exchange data, share information and knowledge, or use functionality of one another.

Another definition has recently been provided by the Athena project [86.8]. It defines interoperability of enterprise applications as the ability of a system to work with other systems without special effort on the part of their users.

More broadly speaking, enterprise interoperability can be defined as the ability of an enterprise to use information or services provided by one or more other enterprises. This assumes on the part of the IT infrastructure the ability to send and receive messages (requests or responses) or data streams. These exchanges can be made in synchronous or asynchronous mode depending on communication needs.

Interoperability is indeed one of the many facets of enterprise integration. An integrated family of systems must necessarily be interoperable in one form or another. Interoperable systems do not need to be integrated. In fact, enterprise interoperability equates to loosely coupled enterprise integration. It provides two or more business entities (of the same organization or from different organizations and irrespective of their location) with the ability to exchange or share information (wherever it is and at any time) and to use functions or services of one another in a distributed and heterogeneous environment. Interacting component systems are preserved as they are, can still work on their own, but can at the same time interoperate seamlessly.

As for integrated systems, building and implementing interoperable enterprise systems relies heavily on the use of open standards, as indicated in Sect. 86.3.

86.1.3 Background

Enterprise integration (EI) naturally emerged as a concept in the early 1990s from advances made in the 1980s in computer-integrated manufacturing (CIM) on the one hand and in enterprise information integration (EII) on the other hand. Both were aimed at interconnecting islands of automation and information silos to liquify as much as possible information and control flows across the organization. Distributed computing environments, client–server architectures, federated databases, common network protocols, and remote procedure calls were essential technologies during this early development era.

With the advent of object-oriented computing, open system architectures, and message queuing techniques, complex pieces of middleware emerged in the mid 1990s, the so-called enterprise application integration (EAI) platforms [86.9]. Among these, the common object request broker architecture (CORBA) has played a prominent role because of its open-source nature, as promoted by the Object Management Group [86.10].

It is also at this time that two major IT inventions appeared: hyper-text transfer protocol (HTTP) and extended markup language (XML) (Sect. 86.4). They have drastically changed the scene because these standards opened the door to ubiquitous computing and nearly full independence to specific IT infrastructures (e.g., computer networks, operating systems, computer languages, etc.). This was a major step to get rid of EAI solutions that were found to be too rigid, monolithic, and proprietary solutions and it made possible Internet computing and led to the emergence of web services at the turn of the century.

Since then, while EI has rapidly evolved in the organizational aspect, with new concepts coming from enterprise architectures, business process management (BPM), computer-supported collaborative work (CSCW), and interorganizational workflow systems, the pressure for increased systems interoperability has continuously been accentuated with the growing needs coming from new forms of organizations (e.g., supply chains, extended enterprises or virtual enterprises) in terms of business process coordination and service exchange. Service-oriented architectures (SOA) and web services [86.11, 12] are playing a central role in this area, as explained in the next sections.

86.2 Integration and Interoperability Frameworks

Enterprise integration and interoperability frameworks are made of a set of principles, standards, guidelines, and sometimes models that practitioners should apply to put in place the right components in the proper order to achieve integration and interoperability in their organization.

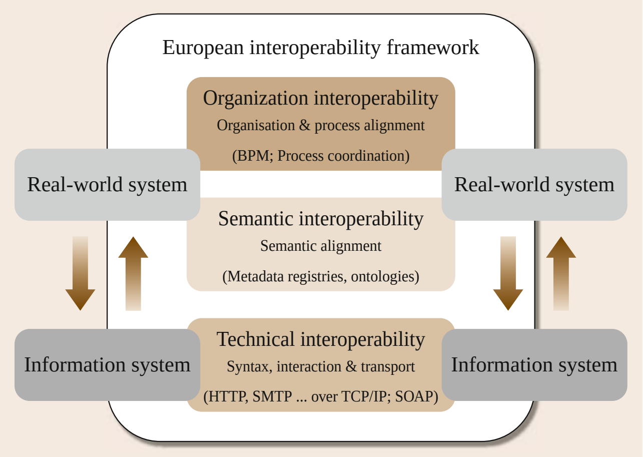
An example EI framework is given by Fig. 86.1. It comes from the computer-integrated manufacturing open system architecture (CIMOSA) architecture that has specifically been designed for CIM, i. e., integration in manufacturing enterprises [86.5]. The framework emphasizes three integration levels, namely systems integration, application integration, and business integration, and positions different technologies or languages to be used at each level.

Other architectures or frameworks exist (e.g., PERA (purdue enterprise reference architecture), ARIS (architecture for information systems), GRAI (graphes de résultats et activités interreliés), GERAM (generalized enterprise reference architecture and methodology), IDEF (integrated definition method), etc.), and have been reviewed in a book by *Vernadat* [86.1].

Similarly, a number of frameworks are being developed for interoperability; for instance, *levels of information systems interoperability* (LISI) from an Architecture Working Group of the US Department of Defense (on Command, Control, Communications, Computers, Intelligence, Surveillance and Reconnaissance – C4ISR) defines five levels of interoperability [86.14]:

- Level 0 – isolated systems (manual extraction and integration of data)
- Level 1 – connected interoperability in a peer-to-peer environment
- Level 2 – functional interoperability in a distributed environment
- Level 3 – domain-based interoperability in an integrated environment
- Level 4 – enterprise-based interoperability in a universal environment.

The European Interoperability Framework (EIF) is a more generic framework jointly developed by the European Commission (EC) and the member states of the European Union (EU) to address business and government needs for information exchange [86.13]. This framework defines three essential levels (or dimensions) of interoperability, namely technical, semantic, and organizational from bottom up, as depicted by Fig. 86.2. These dimensions are further explained in the next sections.



European interoperability framework
Organization interoperability
Organisation & process alignment
(BPM; Process coordination)
Real-world system
Real-world system
Semantic interoperability
Semantic alignment
(Metadata registries, ontologies)
Technical interoperability
Syntax, interaction & transport
(HTTP, SMTP ... over TCP/IP; SOAP)
Information system
Information system

Fig. 86.2 European Interoperability Framework (EIF) (after [86.13])

86.2.1 Technical Interoperability

This dimension covers technical issues or *plumbing* aspects of interoperability. It deals with connectivity and is to date the most developed dimension. It ensures that systems get physically connected and that data and messages can be reliably transferred across systems. It is about linking computer systems and applications or interconnecting information systems by means of so-called middleware components. It includes key aspects such as open interfaces, interconnection services, data transport, data presentation and exchange, accessibility, and security services.

At the very bottom level are network protocols (TCP/IP (transmission control protocol/internet protocol)) and on top transport protocols such (HTTP, SMTP (simple mail transfer protocol), etc.) to exchange data in the form of XML messages.

86.2.2 Semantic Interoperability

This dimension of interoperability concerns semantic alignment, i. e., the ability to achieve meaningful exchange and sharing of information, and not only data, among independently developed systems. It is concerned with ensuring that the precise meaning of exchanged information is understandable by any other application that was not initially developed for this purpose.

Semantic interoperability enables systems to reformat or adapt received information (e.g., convert euros into dollars) or combine it with other information resources and to process it in a meaningful manner for the recipient. It is therefore a prerequisite for the front-end (multilingual) delivery of services to users.

Beyond information system interoperability, cooperation between systems should also be possible. This means that the different systems must be able to provide each other context-aware services, i. e., services that can be used in different types of situations, that they can call or that they can use to enable the emergence of higher-level composite services.

Technologies involved at this level include metadata registries, thesauri or ontologies to map semantic definitions of the same concepts used by the different systems involved. In IT, an ontology [86.15] is a shared formal specification of some domain knowledge. It is usually expressed in first-order logic or languages such as knowledge query and manipulation language (KQML) to be exchanged with knowledge interchange format (KIF) or in the form of semantic networks or taxonomies, for instance, resource description framework (RDF) and web ontology language (OWL), the World Wide Web Consortium (W3C) web ontology language [86.16].

86.2.3 Organizational Interoperability

This dimension of interoperability is concerned with defining business goals, modeling business processes, and bringing collaboration capabilities to organizations that wish to exchange information and may have different internal structures and processes. Moreover, organizational interoperability aims at addressing the requirements of the user community by making services available, easily identifiable, accessible, and user-centric. In other words, it is the ability of organizations to provide services to each other as well as to users or the wider public.

To achieve organizational interoperability, it is necessary to align business processes of cooperating business entities, define synchronization steps and messages, and define coordination and collaboration mechanisms for interorganizational processes. This requires business process management (BPM) for the modeling and control of these business processes, workflow engines for the coordination of the execution of their steps defined as business services, collaborative tools, and enterprise portals to provide user-friendly access to business services and information pages made available to end-users.

86.3 Standards and Technology for Interoperability

As mentioned in the previous sections, a certain number of standards and technologies need to be considered to achieve the three levels of enterprise integration and interoperability. Essential ones include (from bottom up of Fig. 86.1):

1. *XML*: The extended markup language is a widely used, standardized tagged language proposed and maintained by the World Wide Web Consortium (W3C). It has been proposed to be a universal format for structured content and data on the web but can indeed be used for any computer-based exchange. Its simple and open structure has revolutionized data, information, and request/reply exchanges among computer systems because XML messages can be handled by virtually any transport protocol due to its alphanumeric and platform-independent nature [86.17].
2. *HTTP*/*HTTPS*: Hypertext transfer protocol is the set of rules for transferring files (text, graphic images,

sound, video, and other multimedia files) on the World Wide Web. HTTP is an application protocol that runs on top of the TCP/IP suite of protocols. Because of its ubiquity it has become an essential standard for communications. HTTP 1.1 is the current version (http://www.w3.org/Protocols/).

3. *Web services* and *service-oriented architectures* (SOAs): Since the year 2000, service-oriented architectures represent a new generation of IT system architectures taking advantage of message-oriented, loosely coupled, asynchronous systems as well as web services [86.11, 12, 18]. SOAs provide business analysts, integration architects, and IT developers with a broad abstract view of applications and integration components to be dealt with as encapsulated and reusable high-level services. Web services can be defined as interoperable software objects that can be assembled over the Internet using standard protocols and exchange formats to perform functions or execute business processes [86.12]. They are accessible by the external world by their unique resource locator (URL), they are described by their interface, and can be implemented in any computer language. Web services use the following de facto standards for their implementation:
   - *WSDL*: The web service description language is a contract language used to declare the web service interface and access methods in a universal language using specific description templates [86.19].
   - *SOAP*: The simple object access protocol is a communication protocol and a message layout specification that defines a uniform way of passing XML-encoded data between two interacting software entities (for instance, web services). SOAP is under consideration by the World Wide Web Consortium to become a standard in the field of Internet computing [86.20]. It still lacks security mechanisms for the transfer of sensitive data and messages but can deal with data encryption.
   - *UDDI*: The universal description, discovery, and integration specification is an XML-based registry proposal for worldwide businesses to list their services offered on the Internet as web services. The goal is to streamline online transactions by enabling companies to find one another on the web and make their services interoperable for e-Commerce. UDDI is often compared to a telephone book's white, yellow, and green pages. Within a company or within a network of companies, a private service registry can be established in a similar way and format to UDDI in order to manage all shared business and data services used across the business units.
4. *Service registries*: A service registry is a metadata repository that maintains a common description of all services registered for the functional domain for which it has been set up. Services are described by their name, their owner, their service level agreement and quality of service, their location, and their access method. It is used by service owners to expose their services and by services users to locate services. Commercial products based on UDDI specs are available.
5. *Message and service buses – MOM/ESB*: The key to building interoperable enterprise systems and service-oriented architectures that are reliable and scalable is to ensure loose coupling among services and applications. This can be achieved using message queuing techniques, and especially message-oriented middleware (MOM) products and their recent extension known as enterprise service buses (ESB) [86.4, 21]. Services and IT applications exchange messages in a neutral format (preferably XML) using simple transport protocols (i. e., XML/SOAP on TCP/IP, SMTP or HTTP). A message-oriented middleware is a messaging system that provides the ability to connect applications in an asynchronous message exchange fashion using message queues. It provides the ability to create and manage message queues, to manage the routing of messages, and to fix priorities of messages. Messages can be delivered according to three basic messaging models:
   - Point-to-point model, in which only one consumer may receive messages that are sent to a queue by one or more producers
   - Publish-and-subscribe, in which multiple consumers may register, or subscribe, to receive messages (called topics) from the same message queue
   - Request/reply, which allows reliable bidirectional communications between two peer systems (using input queues and output queues)

   An enterprise service bus goes beyond the capabilities of a MOM. It is a standards-based integration platform that combines messaging of a MOM, web services, data transformation, database access services, intelligent routing of messages, and even workflow execution to reliably connect and coordinate the interaction of significant numbers of diverse applications across an extended organization with transactional integrity. It is capable of being adopted for any general-purpose integration project and can scale beyond the limits of a hub-and-spoke EAI broker. Data transformation is the ability to apply XSLT (extended style sheet transformation) (or XML style sheets) to XML messages to reformat messages during transport depending on the type of receivers that will consume the messages (for instance, the ZIP code is a separate information datum for one application while it is part of a customer address for another one). Intelligent or rule-based routing is the ability to use message properties to route message delivery to different queues according to message content. Database services simplify access to database systems using SQL (structured query language) and Java database connectivity (JDBC) or object database connectivity (ODBC). Useful enterprise integration patterns to be used in messaging applications can be found in the book by *Hohpe* and *Woolf* [86.4], who have thoroughly analyzed and described those that are most commonly used in practice.

6. *BPM*: Business process management consists of reviewing, reengineering, and automating business processes of the organization. Among the process steps are services offered by IT systems. Once automated, these processes take the form of workflows. Two languages can be used to model business processes, one at the business user level and one at the workflow system level. These are:
   - BPMN: The business process modeling notation is a diagrammatic and semistructured notation that provides businesses with the capability to represent their internal business procedures in a graphical language. It gives organizations the ability to depict and communicate these procedures in a standard manner. Furthermore, the graphical notation facilitates the understanding of the performance of collaborations and business transactions between the organizations. This ensures that business participants will understand each other and that participants in the business will enable organizations to adjust to new internal and B2B business circumstances quickly [86.22].
   - BPEL: The business process execution language is an XML-based language designed to enable task sharing for a distributed computing environment – even across multiple organizations – using a combination of web services (BPEL is also sometimes called BPEL4WS or BPELWS). It has been written by developers from BEA Systems, IBM, and Microsoft. BPEL specifies the business process logic that defines choreography of interactions between a number of web services. The BPEL standard defines the structure, tags, and attributes of an XML document that corresponds to a valid BPEL specification [86.23]. Conversion mechanisms exist to translate BPMN models into BPEL specifications.

86.4 Applications and Future Trends

Enterprise integration has been around in terms of applications since the beginning of the 1990s, especially in the domain of manufacturing integration but also enterprise information integration (EII), enterprise resources planning (ERP), customer relationship management (CRM), and then supply chains. The advent of CORBA, workflow engines, and BPM techniques has given birth to a range of commercial products, known as enterprise application integration (EAI) platforms. Many vendors have proposed solutions, including Iona, Sopra, Vitria, Tibco, Microsoft BizTalk, HP, IBM, Oracle, and BEA Systems, as well open-source solutions.

Today, nearly all industrial sectors are facing integration and interoperability problems, ranging from manufacturing supply chains to banking, the insurance sector, medical services, and public organizations. The focus is on XML-based messaging communications and loosely coupled interactions thanks to XML/HTTP and MOM/ESB techniques. One area that has emerged with EI and is rapidly growing is electronic commerce (web-based shopping, B2B commerce, e-Procurement, electronic payment, EDI, etc.). Major initiatives launched to sustain this area include ebXML (electronic business XML) for XML/EDI (electronic data interchange) (UN/CEFACT (United Nations Centre for Trade Facilitation and Electronic Business) and OASIS (Organization for the Advancement of Structured Information Standards)), RosettaNet (www.rosettanet.org) in the area of standard electronic data exchange for supply chains, and Bolero.net (www.bolero.net) proposing a data and document exchange infrastructure for international commerce involving SWIFT (Society for Worldwide Interbank Financial Telecommunication) for secured payment.

In terms of current trends that can be observed there is a shift from the pure business process paradigm that prevailed through the 1990s to the service-orientation paradigm. This puts more emphasis on services interoperability than on IT systems interoperability or enterprise application integration than before [86.25].

Among the future trends, we can mention the emergence of composite services, i. e., services made of services. This will rapidly grow both in business (to combine competencies and capabilities of several partners into common services) and in government organizations (for instance, pan-European services offered to EU citizens where a service offered to citizens through a common portal will in fact be a combination of local services running in member states in national languages, e.g., application for the blue card or European identity card).

At the technical level, integration and interoperability are still evolving and will continue to evolve with technology (faster communication networks, authentication mechanisms, security issues, electronic signature, multilingual issues, etc.).

At the semantic level, many researchers agree that one of the major challenges for integration and interoperability remains the semantic unification of concepts. There are simply too many ontologies around and no common way of representing these ontologies, although OWL-S is a de facto standard. Microtheories have to emerge to provide sound foundations for the field, and

(XML-based) standards for ontology representation are needed.

At the organizational level, many techniques and languages exist to capture and represent business processes and services in a satisfactory way for business users. The research trends should focus on developing interoperability maturity models with associated metrics to assess the level of integration or interoperability and propose methodologies for improving enterprise integration or interoperability.

Anyway, for the years to come, the driving forces imposing the new trends will continue to come from market globalization and new business conditions: need for more joint ventures, increased communication, fusion and acquisition, knowledge sharing, or use of common skills and competencies.

86.5 Conclusion

Thanks to advances in Internet computing and service orientation, enterprise integration and systems interoperability have become a reality that largely contributes to make enterprises more agile, more collaborative, and more interoperable. The reader should also see Chap. 88 on *Collaborative e-Work, e-Business, and e-Service* and Chap. 90 on *Business Process Automation: CRM, SCM and ERP* for related content.

Enterprise integration and systems interoperability are fairly mature at the technical level, and will continue to evolve with new IT technologies, but are not yet completely addressed at the organizational and more specifically at the semantic level.

There are however some other issues (out of the scope of this chapter) that should be considered. They concern legal issues, confidentiality issues, or linguistic aspects, to name a few, especially in the case of international contexts (multinational firms, international organizations or unions of member states). They can have a political dimension and be even harder to solve than pure technical or organizational issues mentioned in this chapter.

87. Decision Support Systems

Daniel J. Power, Ramesh Sharda

This chapter places decision automation in a broader context of using information technologies in decision making. Key definitions and a brief history of computerized decision support create important boundaries. Then a description and explanation of characteristics of computerized decision support systems (DSS) clarifies this application domain. After reviewing management information needs, a modern taxonomy of decision support systems is briefly summarized. Issues associated with building DSS and various architectures are reviewed before concluding the overview.

Decision support systems (DSS) are defined broadly as interactive computer-based systems that help people use computer communications, data, documents, knowledge, and models to solve problems and make decisions (see DSSResources.com). DSS are ancillary or auxiliary systems; they are not intended to replace skilled decision-makers. DSS are not automating decision-making.

In pursuing the goal of improving decision-making, many different types of computerized DSS have been built to help decision teams and individual decision-makers. Some systems provide structured information directly to managers. Other systems help managers and staff specialists analyze situations using various types of quantitative models. Some DSS store knowledge and make it available to managers. Some systems support decision-making by small and large groups. Companies even develop DSS to support the decision-making of their customers and suppliers.

Table 87.1 identifies some major developments in the history of decision support systems. For more details see *Power* [87.1, 2].

The history of decision support systems (based on [87.2]) is relatively brief and the concepts and

Table 87.1 Evolution of DSS concepts

1980s	Key DSS books Group DSS prototypes Executive information systems (EIS) PC expert systems
1990s	Business intelligence/OLAP Data warehousing Web-based systems/portals Data mining

technologies are still evolving. Today, a number of academic disciplines provide the substantive foundations for decision support systems development and research. Database research has contributed tools and research on managing data and documents. Management science and operations research have developed mathematical models for use in building model-driven DSS and provided evidence on the advantages of modeling in problem solving. Cognitive science, especially behavioral decision-making research, has provided descriptive and empirical information that has assisted in DSS design and has generated hypotheses for decision support research. Some other important fields related to DSS include artificial intelligence, human–computer interaction, software engineering, and telecommunications. In general, the Internet and web have sped up developments in decision support and have made it hard to keep up with the rapid changes in DSS capabilities.

In the 1960s, pioneering work in building interactive systems at the Massachusetts Institute of Technology, theory development by Simon and colleagues, and *Morton*'s [87.3] research created a foundation for building innovative DSS.

In the early 1970s, BrandAid [87.4] and reports of *Morton*'s [87.3] management decision system (MDS) research demonstrated the feasibility of DSS. By the late 1970s, a number of companies had developed interactive information systems that used data and models to help managers analyze semistructured problems. These diverse systems were all called decision support systems. Key concept books included those by *Alter* [87.5], *Sprague* and *Carlson* [87.6], and *Bonczek* et al. [87.7].

From those early days, it was recognized that DSS could be designed to support decision-makers at any level in an organization. DSS could support operations, financial management, and strategic decision-making. Over the years many of the more interesting DSS have been targeted at middle and senior managers. DSS are also often designed for specific types of organizations such as hospitals, banks or insurance companies. These specialized systems are sometimes referred to as vertical-market or industry-specific DSS.

Today, decision support systems are both off-the-shelf, packaged applications and custom-designed systems. DSS may support a manager using a single personal computer or a large group of managers in a networked client–server environment. These latter systems are often called enterprise-wide DSS.

87.1 Characteristics of DSS

Although the term decision support system has many connotations, based upon *Alter*'s [87.5] pioneering research we can identify the following three major characteristics:

1. DSS are designed specifically to facilitate decision processes.
2. DSS should support rather than automate decision-making.
3. DSS should be able to respond quickly to the changing needs of decision-makers.

Many terms are used for specific types of DSS, including business intelligence, collaborative systems, data warehousing, model-based systems, knowledge management, and online analytical processing. Software vendors use these more specialized terms for both descriptive and marketing purposes. What term we use for a system or software package is a secondary concern. Our primary concern should be finding software and systems that meet a manager's decision support needs and provide appropriate management information.

87.1.1 Management Information Needs

Managers and their support staffs need to consider what information and analyses are actually needed to support their management and business activities. Some managers need both detailed transaction data and summarized transaction data. Most managers only want summaries of transactions. Managers usually want lots of charts and graphs; a few only want tables of numbers. Many managers want information provided routinely or periodically and some want information available online and on demand. Managers usually want financial analyses and some managers want primarily *soft*, nonfinancial or qualitative information. Managers have different needs and wants depending upon personal preferences, task needs, and information technology experiences.

In general, a computerized information system can provide business transaction summary information and can help managers understand many business operations and performance issues; for example, a computerized system can help managers understand the status of operations, monitor business results, review customer preference data, and investigate competitor actions. In all of these situations, management information and analyses should have a number of characteristics. Information must be both timely and current. These characteristics mean the information is up to date and available when managers want it. Also, information must be accurate, relevant, and complete. Finally, managers want information presented in a format that assists them in making decisions. In general, management information should be summarized and concise and any support system should have an option for managers to obtain more detailed information.

So the subcategory known as decision support systems needs to provide current, timely information that is accurate, relevant, and complete. A specific DSS must present information in an appropriate format that is easy to understand and manipulate. The information presented by a DSS may result from analysis of transaction data or it may be the result of a decision model or it may have been gathered from external sources. DSS can present internal and external facts, informed opinions, and forecasts to managers. As many others have noted, *managers want the right information, at the right time, in the right format, and at the right cost*. These system requirements seem simple and straightforward, but meeting them remains a challenge.

Technology is creating new decision support capabilities, but much learning and discussion needs to occur to successfully exploit the technological possibilities. Decision support systems differ in many ways from operating systems that process business transactions. For example, a popular system that has been widely implemented is called enterprise resource planning (ERP). ERP is *not* a decision support system even though the term suggests that decision-making and planning will be improved. In general, enterprise resource planning is an integrated transaction processing system that facilitates the flow of information between all of the functional areas of a business. Recently, DSS have been built that help managers analyze the data from ERP systems, and ERP systems make it easier to create a wide variety of DSS.

Decision automation refers to using information technologies to make decisions and implement programmed decision processes. Typically decision automation is considered most appropriate for well-structured, clearly defined, routine or programmed [87.8] decision situations. Decision support systems are intended to help human decision-makers while decision automation systems make a decision and reduce the need for immediate human involvement in the decision. People still write rules and review results for decision automation, but software makes the routine decisions.

A major difference between transaction processing systems, decision automation, and decision support systems is the general purpose of each type of system. Transaction processing systems (TPS) are designed to expedite and automate transaction processing, record keeping, and simple business reporting of transactions. Decision automation uses software to make decisions. Decision support systems are intended to assist in decision-making and decision implementation. Transaction processing is however related to the design of DSS because transaction databases often provide data for decision-oriented reporting systems and data warehouses. Decision automation often interacts with TPS, and the results of automated decisions often impact on TPS.

Transaction processing systems usually provide standard reports on a periodic basis and support the operations of a company. DSS are used on demand when they are needed to support decision-making. A manager typically initiates each instance of decision support system use, either by using the DSS herself or by asking a staff intermediary to use a DSS. Some managers and especially clerical employees use transaction processing systems to support operations. Line managers and support staff are the primary users of DSS. TPS record current information and maintain a database of transaction information. DSS generally use historical internal and external data for analysis. DSS may focus on quantitative analysis and modeling current and future scenarios. TPS emphasize data integrity and consistency, and although both of these qualities are important in every system, the primary emphasis for a DSS is on flexibility and on conducting analyses and retrieving decision-relevant information and knowledge. Decision automation routinizes a specific decision 24 h a day, 7 days a week.

One of the long-standing conclusions from reading DSS case studies is that DSS can *take on many different forms and can be used in many different ways* [87.5]. Decision support systems certainly vary in many ways. Some DSS focus on accessing data, some on manipulating models, and some on facilitating communications.

DSS also differ in scope; some DSS are intended for one *primary* user and are used *stand-alone* for analysis, whereas others are intended for many users in an organization. Also, DSS differ in terms of who uses a specific system; for example, some DSS are used by actual decision-makers and some are used by intermediaries such as marketing analysts or financial analysts. If a computerized system is not a transaction processing system and if a manager uses it, many observers will be tempted to call the system a DSS.

Some examples show the wide variety of DSS applications. Major airlines have DSS used by analysts for many tasks including pricing and route selection. Many companies have DSS that aid in corporate planning and forecasting. Specialists often use these DSS that focus on financial and simulation models. DSS can help monitor costs and revenues and track departmental budgets. Also, investment evaluation and support systems are increasingly common. Frito-Lay has a DSS that aids in pricing, advertising, and promotion. Route salesmen use handheld computers to support decision-making activities.

Many manufacturing companies use manufacturing resources planning (MRP) software. This specific operational-level DSS supports master production scheduling, purchasing, and materials requirements planning. More recent MRP systems support *what-if* analysis and simulation capabilities. DSS support quality improvement and control decisions. Monsanto, FedEx, and most transportation companies use DSS for scheduling trucks, airplanes, and ships. The Coast Guard uses a DSS for procurement decisions. Companies such as Wal-Mart have large data warehouses and use data-mining software. Business intelligence and knowledge management systems are increasingly common. On the World Wide Web one can find DSS that help track and manage stock portfolios, choose stocks, plan trips, and suggest gifts. DSS support distributed decision activities using groupware and a corporate intranet.

The following expanded DSS framework helps categorize the most common DSS currently in use [87.1, 9, 10]. Some DSS are integrated or hybrid systems with more than one major DSS subsystem. The framework focuses on one major capability dimension with five categories and three secondary dimensions. The term *driver* is used as a common or shared descriptive adjective in the expanded framework. *Driver* refers to the capability, tool or component that is providing the dominant functionality in the DSS. The five categories explained below are communications-driven, data-driven, document-driven, knowledge-driven, and model-driven.

87.1.2 Communications-Driven and Group DSS

Group decision support systems (GDSS) and groupware were investigated in the mid-1980s, but now a broader category of *communications-driven DSS* can be identified. This type of decision support system includes communication, collaboration, and decision support. A group DSS is an interactive computer-based system intended to facilitate the solution of problems by decision-makers working together as a group; such systems often derive functionality from a model more than from supporting collaboration and hence are model-driven DSS. Groupware supports electronic communication, scheduling, document sharing, and other group productivity and decision support enhancing activities. A number of technologies and capabilities are included in this category in the framework: some collaborative group DSS, two-way interactive video, white boards, bulletin boards, chat, and email systems.

87.1.3 Data-Driven DSS

Data-driven DSS emphasize analysis of data. These systems include file drawer and management reporting systems, data warehousing and analysis systems, executive information systems (EIS), and data-driven spatial decision support systems (SDSS). EIS are targeted at senior managers and SDSS display spatial data for decision support. Business intelligence (BI) systems are also examples of data-driven DSS. A data-driven DSS provides access to and manipulation of large databases of structured data and especially a time series of internal company data and external data. Simple file systems accessed by query and retrieval tools provide the most elementary level of functionality. Data warehouse systems that allow the manipulation of data by computerized tools tailored to a specific task and setting or by more general tools and operators provide additional functionality. Data-driven DSS with online analytical processing (OLAP) provide the highest level of functionality and decision support that is linked to analysis of large collections of historical data [87.11].

87.1.4 Document-Driven DSS

A new type of DSS, a *document-driven DSS*, is evolving to help managers retrieve and manage unstructured documents and web pages. A document-driven DSS integrates a variety of storage and processing technologies to provide complete document retrieval and analysis. The web provides access to large document databases including databases of hypertext documents, images, sounds, and video. Examples of documents that would be accessed by a document-driven DSS are policies and procedures, product specifications, catalogs, and corporate historical documents, including minutes of meetings, corporate records, and important correspondence. A search engine is a powerful decision-aiding tool associated with a document-driven DSS. Some authors call this type of system a knowledge management system.

87.1.5 Knowledge-Driven DSS

The terminology for this fourth category of DSS is still evolving. Currently, the best term seems to be *knowledge-driven DSS*. Sometimes it seems equally appropriate to use *Alter*'s [87.5] term *suggestion DSS* or the narrower term *management expert system*. Knowledge-driven DSS suggest or recommend actions to managers. These DSS have specialized problem-solving expertise. The *expertise* consists of knowledge about a particular domain, understanding of problems within that domain, and *skill* at solving some of these problems.

87.1.6 Model-Driven DSS

A fifth category, *model-driven DSS*, includes systems that use accounting and financial models, representational models, and optimization models. Model-driven DSS emphasize access to and manipulation of a quantitative model. Simple statistical and analytical tools provide the most elementary level of functionality. Some OLAP systems that allow complex analysis of data may be classified as hybrid DSS systems providing modeling, data retrieval, and data summarization functionality. Model-driven DSS use data and parameters provided by decision-makers to aid them in analyzing a situation, but they are not usually data intensive. Very large databases are usually not needed for model-driven DSS, but data for a specific analysis may need to be extracted from a large database.

87.1.7 Secondary Dimensions

The secondary dimensions used to describe DSS include purpose, targeted users, and the enabling technology. A relatively new category of DSS made possible by new technologies and the rapid growth of the public Internet is *interorganizational DSS*. These DSS target a company's customers or suppliers. The public Internet is creating communication links for many types of interorganizational systems, including DSS. An interorganizational DSS provides external stakeholders with access to a company's intranet and authority or privileges to use specific DSS capabilities. Companies can make a data-driven DSS available to suppliers or a model-driven DSS available to customers to design a product or choose a product. Most DSS are *intra-organizational DSS* that are designed for use by managers in a company as *stand-alone DSS* or for use by a group of managers in a company as a group or enterprise-wide DSS.

Many DSS are designed to support specific business functions or types of businesses and industries. These are broad- or narrow-purpose DSS. Such DSS can be labeled as function-specific or industry-specific purpose DSS.

A *function-specific DSS* such as a budgeting system may be purchased from a vendor or customized in-house using a more general-purpose development package. Vendor developed or off-the-shelf DSS support functional areas of a business such as marketing or finance; some DSS products are designed to support decision tasks in a specific industry such as a crew scheduling DSS for an airline. A function or task-specific DSS has an important purpose in solving a recurring decision task. Function- or task-specific DSS can be further classified and understood in terms of the dominant DSS component in the DSS. So, a function-specific DSS may be model driven, data driven, document driven or knowledge-driven. These DSS have capabilities relevant for a decision about some function that an organization performs (e.g., a marketing function or a production function). These DSS are categorized by purpose: function-specific DSS help a person or group accomplish a specific decision task; general-purpose DSS software helps support broad tasks such as business performance monitoring, business intelligence, project management, and decision analysis.

All five broad categories of decision support systems can be implemented using web technologies. When the enabling technology used to build a DSS is the Internet and web is seems appropriate to call the system a web-based DSS. A *web-based DSS* is a computerized system that delivers decision support

Table 87.2 An expanded DSS framework (after [87.1])

Dominant DSS component	User groups: internal, external	Purpose: general, specific	Enabling technology
Communications *Communications-driven DSS*	Internal teams, now expanding	Conduct a meeting Bulletin board Help users collaborate	Web or client/server
Database *Data-driven DSS*	Managers, staff, now suppliers	Query a data warehouse	Main frame, client/server, web
Document base *Document-driven DSS*	Specialists and user group is expanding	Search web pages, find documents	Web
Knowledge base *Knowledge-driven DSS*	Internal users, now customers	Management advice, choose products	Client/server, web
Models *Model-driven DSS*	Managers and staff, now customers	Crew scheduling Decision analysis	Stand-alone PC

information or decision support tools to a manager or business analyst using a *thin-client* web browser such as FireFox or Internet Explorer [87.1]. The computer server that is hosting the DSS application is linked to the user's computer by a network with the transmission control protocol/Internet protocol (TCP/IP). In many companies, a web-based DSS is synonymous with an intranet or enterprise-wide DSS. Web technologies are powerful tools for creating decision support systems and especially interorganizational DSS that support the decision-making of customers and suppliers. Web 2.0 technologies are the leading edge for building DSS, but some DSS will continue to be built using mainframe and client–server enabling technologies.

Column one of Table 87.2 lists the five broad categories of decision support systems that differ in terms of the dominant decision support component, including communications-driven DSS, data-driven DSS, document-driven DSS, knowledge-driven DSS, and model-driven DSS. The table provides examples of targeted user groups – intra-organizational and interorganizational, purpose, and enabling technologies.

One can use the dominant DSS architecture component, targeted user group, purpose, and the enabling technology to describe a specific decision support system. For example, a manager may want to build a model-driven, intra-organizational, product design, web-based DSS to support a specific business decision process.

87.2 Building Decision Support Systems

Traditionally, information systems academics and practitioners have discussed building decision support systems in terms of four major components:

1. The user interface
2. The database
3. The models and analytical tools
4. The DSS architecture and network [87.6].

This traditional list of components remains useful because it identifies similarities and differences between categories or types of DSS and it can help managers and analysts build new decision support systems. The expanded DSS framework [87.1, 9, 10] is based on the different emphases placed on DSS components when a specific system is actually constructed (Fig. 87.1).

Data-driven, document-driven, and knowledge-driven DSS need specialized database components. A model-driven DSS may use a simple flat-file database with fewer than 1000 records, but the model component is very important. Experience and some empirical evidence indicate that design and implementation issues vary for data-driven, document-driven, model-driven, and knowledge-driven DSS. Multiparticipant systems such as group and interorganizational DSS also create complex implementation issues. For instance, when implementing a data-driven DSS a designer should be especially concerned about the user's interest in applying the DSS in unanticipated or novel situations.

In creating an accounting or financial simulation model, a developer should attempt to verify that the initial input estimates for the model are thoughtful and reasonable. In developing a representational or optimization model, an analyst should be concerned about possible misunderstandings of what the model means and how it can or cannot be used [87.5]. Networking issues create challenges for many types of DSS, but especially for communications-driven systems with many participants, so-called multiparticipant systems. Today, architecture and networking issues are increasingly important in building DSS.

DSS should be built or implemented using an appropriate process. Many small, specialized model-driven DSS are built quickly. Large, enterprise-wide DSS are built using sophisticated tools and systematic and structured systems analysis and development approaches. Communications-driven and group DSS are usually purchased as off-the-shelf software and then implemented in a company. Creating enterprise-wide DSS environments remains an iterative and evolutionary task. An enterprise-wide DSS grows and inevitably becomes a major part of the overall information systems infrastructure of an organization. Despite the significant differences created by the specific task and scope of a DSS, all DSS have similar technical components and share a common purpose: supporting decision-making.

A data-driven DSS database is often a collection of current and historical structured data from a number of sources that have been organized for easy access and analysis. We are expanding the data component to include unstructured documents in document-driven DSS and *knowledge* in the form of rules in knowledge-driven DSS. Large databases of structured data in enterprise-wide DSS are often called data warehouses or data marts. DSS usually use data that has been extracted from all relevant internal and external databases. Managing information often means managing a database. Supporting management decision-making means that computerized tools are used to make sense of the structured data or documents in a database.

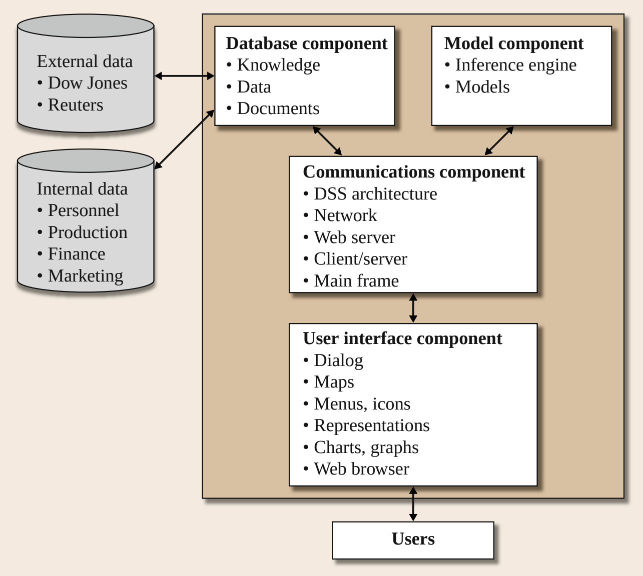

Fig. 87.1 Traditional DSS components [87.1]

Mathematical and analytical models are the major component of a model-driven DSS. DSS models should be used and manipulated directly by managers and staff specialists. Each model-driven DSS has a specific set of purposes and hence different models are needed and used. Choosing appropriate models is a key design issue. Also, the software used for creating specific models needs to manage needed data and the user interface. In model-driven DSS the values of key variables or parameters are changed, often repeatedly, to reflect potential changes in supply, production, the economy, sales, the marketplace, costs, and/or other environmental and internal factors. Information from the models is then analyzed and evaluated by the decision-maker. Knowledge-driven DSS use special models, an inference engine, for processing rules or identifying relationships in data.

The communications component refers to how hardware is organized, how software and data are distributed in the system, and how components of the system are integrated and connected. A major issue today is whether decision support systems should be available using a web browser on a company intranet and also available on the global Internet. Managers and information systems (IS) staff both need to develop an understanding of the technical issues and the security issues related to DSS architectures, networks, and the Internet. Networking technology is the key driver of communications-driven DSS.

Managers and DSS analysts both need to emphasize the user interface component. In many ways the user interface is the most important component. The tools for building the user interface are sometimes termed DSS generators, query and reporting tools, and front-end development packages. Much of the DSS design and development effort should focus on building the user interface. It is important to remember that the screens and displays in the user interface heavily influence how a manager perceives a DSS, as what one sees is the DSS.

The technologies and software associated with decision support systems continues to change rapidly, and development tools are overlapping for some applications. In general, managers and IS staff need to recognize that the overall technological and social context of DSS and business management is changing.

87.3 DSS Architecture

Many academics discuss building decision support systems in terms of the four major components (Fig. 87.2). These components collectively comprise the overall architecture of a DSS. This traditional view of DSS components remains useful because it identifies commonalties between different types of DSS, but it provides only an initial perspective for understanding the complexity of DSS architectures.

As noted in the last section, a major component in the architecture of a DSS is the user interface. The tools for building the user interface are sometimes termed DSS generators, query and reporting tools, and front-end development packages. DSS user interfaces can be distributed to clients in a *thick-client* architecture or delivered over a network using web pages or Java applets in a *thin-client* architecture. A thin-client architecture where a user interacts using a web browser has many advantages, but until recently the sophistication of the user interface was limited compared with a thick-client architecture where a program resides on a DSS user's computer.

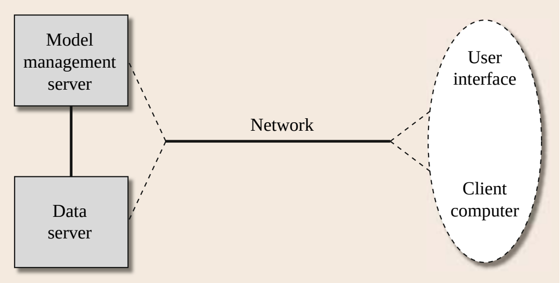

Fig. 87.2 DSS components (after [87.1])

A DSS database is a collection of data organized for easy access and analysis. Large databases in enterprise-wide DSS are often called data warehouses or data marts. Document or unstructured data is stored differently than structured data. Web servers provide a powerful platform for unstructured data and documents. The architecture for a data-driven DSS often involves databases on multiple servers, specialized hardware, and in some cases both multidimensional and

Table 87.3 Selected resources for DSS

Resource Type	Exemplars

Power: *Decision Support Systems Hyperbook*, http://dssresources.com/dssbook/ (Fall, 2000) Turban, Aronson, Liang, Sharda: *Decision Support and Business Intelligence Systems*, 8th ed. (Prentice Hall, Upper Saddle River 2007)

relational database software. The extraction, transformation, loading, and indexing of structured DSS data is sometimes very difficult.

As noted before, quantitative models are an important part of many DSS, especially model-driven DSS. Model management software can be centralized on a server with a database, or specific models can be distributed to client computers. Java applets and JavaScript programs provide a powerful new means to deliver models to users in a thin-client architecture.

The DSS network component refers to how hardware is organized, how software and data are distributed in the system, and how components of the DSS are integrated and physically connected. An ongoing issue is whether a specific DSS should only be available using thin-client technology on a company intranet or available on the global Internet. This should depend on the needs analysis and a feasibility study. Scalability is also an important DSS issue. Scalability refers to the ability to *scale* hardware and software to support larger or smaller volumes of data, and more or fewer users. Scalability also refers to the possibility of increasing or decreasing size or capability of a DSS in cost-effective increments.

Table 87.3 provides selected additional readings and other resources for exploring DSS applications and technologies. These include web resources, text books, and selected journal articles in addition to those included in the references.

87.4 Conclusions

The DSS design and development environment is changing as rapidly as the innovation in hardware and software tools that are available to build them, and in general the change is in a positive a direction. Web and mobile technologies will facilitate improved DSS tools.

Decision support systems are not a panacea for improving business decisions. Most people acknowledge that managers need *good* information to manage effectively, but a DSS is not always the solution for providing *good* information. A DSS can provide a competitive advantage and a company may need computerized decision support to remain competitive, but decision support capabilities are limited by the data that can be obtained, the cost of obtaining, processing, and storing the information, the cost of retrieval and distribution, the value of the information to the user, and the capability of managers to accept and act on the information. Our capabilities to support decision-making have increased, but we still have very real technical, social, interpersonal, and political problems that must be overcome when we build a specific DSS.

Computerized DSS assume that managers need to be kept in the decision-making loop but that managers need and want help to improve their decision-making. When it is possible and appropriate to automate decision-making using software then we have chosen to remove a human decision-maker from the decision-making process. Managers choose to automate, create computerized support or make unaided decisions.

88. Collaborative e-Work, e-Business, and e-Service

Juan D. Velásquez, Shimon Y. Nof

A major part of automation today is represented by collaborative e-Work, e-Business, and e-Service. In this chapter the fundamental theories and scope of collaborative e-Work and collaborative control theory (CCT) are reviewed, along with design principles for effectiveness in the design and operation of their automation solutions. The potential benefits, opportunities, and sustainability of emerging electronic activities, such as virtual manufacturing, e-Healthcare, automated inspection, e-Supply, e-Production, e-Collaboration, e-Logistics, and other e-Activities, will not materialize without the design of effective e-Work. For instance, without automatic error prevention or recovery, e-Activities in complex systems will collapse. The *four-wheels* of collaborative e-Work, their respective 15 e-Dimensions, and their role in e-Business and e-Service are explained and illustrated. Case studies of e-Work, e-Manufacturing, e-Logistics, e-Business and e-Service are also provided to enable readers to get a glimpse into the depth and breadth of ongoing efforts and potential inhibitors to revolutionize such e-Systems. Challenges and emerging solutions are discussed to stimulate readers to push the boundaries of collaborative e-Work.

88.1 Background and Definitions

The landscape in which everyday work and personal activities are accomplished by humans, computers, machines, and organizations has evolved significantly in recent years. From a production point of view, specifically, work has been reshaped by e-Work from the smallest level systems, micro- and nanosystems, all the way up to global enterprises. Just as work, business, commerce, and service are different from each other, so are e-Work, e-Business, e-Commerce, and e-Service. They are highly related, yet they are not the same (Fig. 88.1), and therefore some definitions are needed.

e-Business is the integration of a company's business, including products, procedures, and services, over the Internet [88.1]. A more comprehensive definition

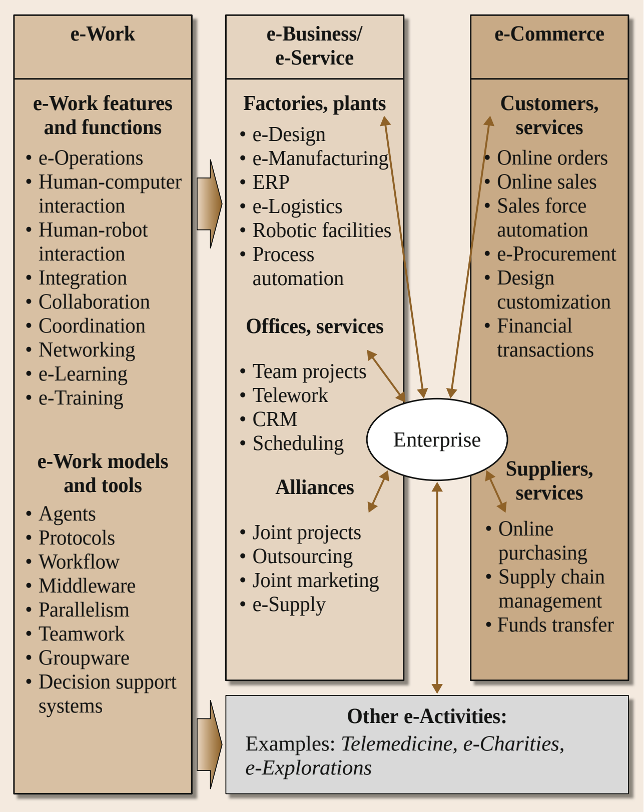

Fig. 88.1 e-Work as the foundation for e-Business, e-Service, e-Commerce, and other e-Activities (after [88.3])

provided by *Browne* et al. [88.2] states that e-Business is about conducting business both internally and/or externally by electronic means, e.g., over the Internet, intranet or extranet, and that it involves not only buying and selling but also operating automated, efficient internal business processes servicing customers and collaborating with suppliers and business partners (Fig. 88.2).

e-Commerce covers the range of online business activities for products and services, both business-to-business and business-to-consumer, through the Internet [88.1].

e-Service is the provision of services over electronic networks such as the Internet, intranets or extranets without its scope being limited to service organizations but rather encompassing all enterprises, even those that manufacture goods and which require the development and implementation of sound service practices over electronic networks.

e-Work are the e-Operations, e-Functions, and e-Support that enable the e-Business, e-Commerce and e-Service activities defined above. Its formal definition describes it as any collaborative, computer-supported and communication-enabled activities in highly distributed networks of humans and/or robots and autonomous systems [88.3]. Among the activities comprised by e-Work are e-Business, e-Commerce, e-Manufacturing, e-Healthcare, e-Training, e-Logistics, virtual (v-)Factories, v-Enterprises, and many more (Fig. 88.3). The activities mentioned above, as well as all others influenced by e-Work, rely on the use of computer support and communication technologies and at the same time require a certain degree of collaboration to support the interactions between humans, computers, and machines.

The transformative influence of e-Work can be summarized in this quote [88.3]:

> *As power fields, such as magnetic fields and gravitation, influence bodies to organize and stabilize, so does the sphere of computing and information technologies. It envelops us and influences us to organize our work systems in a different way, and purposefully, to stabilize work while effectively producing the desired outcomes.*

Often the terms *collaboration* and *coordination* are used interchangeably, and even though they are closely related, they do exhibit significant differences. *Camarinha-Matos* and *Afsarmanesh* [88.4,5] and *Nof* [88.6] provide a number of definitions that help clarify the scope and breadth of each term by placing them in a broader context, which also includes closely related terms such as networking and cooperation. It is important to highlight the differences between all these terms, as their implications on the design of e-Work are crucial (Fig. 88.4).

Coordination involves the use of communication and information exchange to reach mutual benefits among parties by working harmoniously.

Cooperation involves all aspects of coordination but also incorporates a resource-sharing dimension to support goal achievement. Commonly, cooperation will exhibit a component of division of labor among all participants and therefore the aggregated value is the result of adding the *individual* parts.

Collaboration is the most demanding of the three processes, where all involved parties share information, resources, and responsibilities to jointly plan,

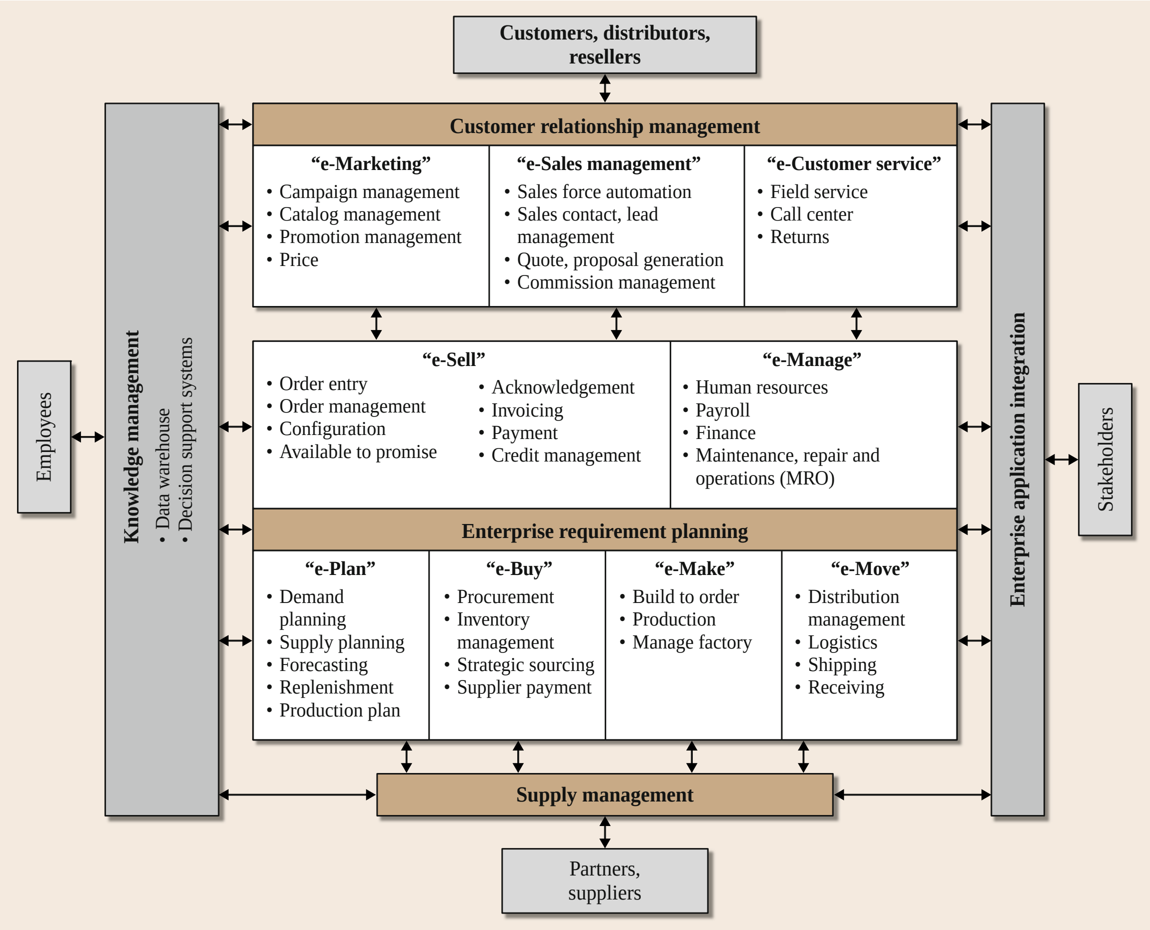

Fig. 88.2 e-Business application framework (after [88.7] with permission from Taylor and Francis)

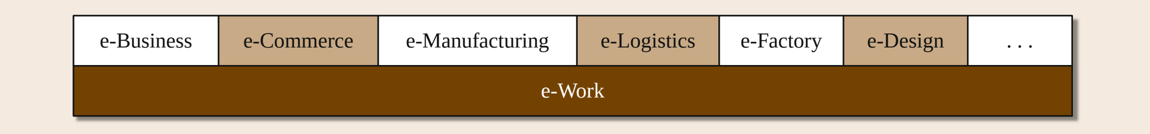

Fig. 88.3 Scope of collaborative e-Work as the common foundation of e-Activities (after [88.8])

implement, and assess the set of activities required to achieve a common goal, thus jointly creating added value.

Over the years, computers and advances in communication technologies and related areas have enabled us to significantly improve the quality of service and products, as well as the level of customization. Specifically, *collaborative e-Work* is revolutionizing the capabilities of e-Business, e-Production, and e-Service. By leveraging existing and well-established work, business and service models, theories, and solutions with the new electronic world, it is possible to augment companies' abilities to significantly better meet customers' needs. In the next section, the four knowledge clusters of e-Work and their related 15 dimensions are discussed in detail.

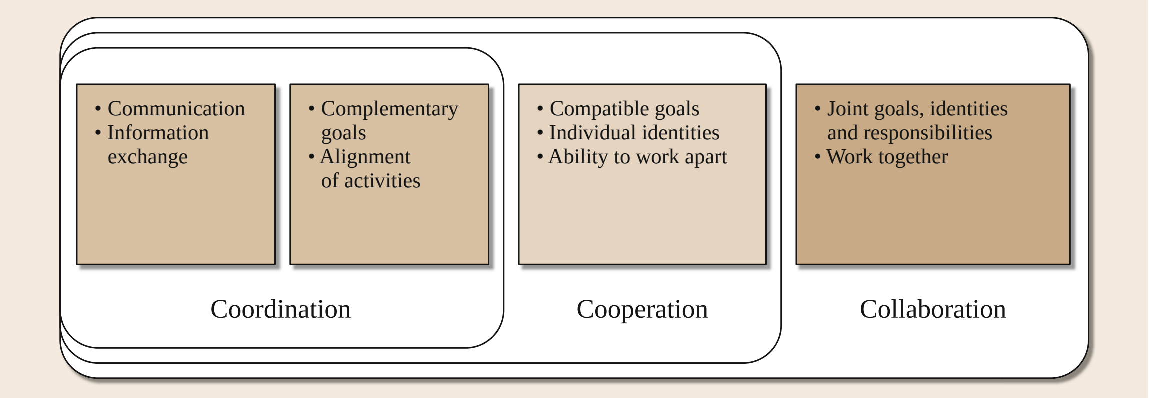

Fig. 88.4 Coordination, cooperation, and collaboration levels of interaction

88.2 Theoretical Foundations of e-Work and Collaborative Control Theory (CCT)

Collaborative control theory (CCT) has been developed over the last decade to support the effective design of collaborative e-Work, e-Business, and e-Service systems, and includes several design principles [88.9–11]. Many researchers have contributed to CCT (e.g., see survey in [88.3]) and have addressed issues of collaborative performance. For instance, *collaborative intelligence* has been defined as a measure of the collaborative ability of an interacting, distributed group or organization, whether of humans and/or agents, robots, sensors, etc. The major tradeoff that CCT addresses is that with a larger number of collaborating participants in a more complex, large-scale system; the knowledge and performance generated from collaborative efforts can increase proportionally to the reach of the network, but conversely the number of conflicts, delays, and errors increases too, up to ineffectiveness, reduction in value, and collapse. To support the collaboration effort, e-Support is essential so that participants can interact in real time or asynchronously even though they are not located within the same physical location. Technologies used to enhance distributed collaboration and to facilitate group problem-solving and decision-making include messaging software, coordination protocols, task administration protocols, and other e-Support techniques and tools:

1. Group moderation and facilitation
2. Agreement to adhere to a set of fundamental rules relating to participant interactions
3. Frequent sharing of feedback
4. Frequent service reviews and agreements on progress and plans
5. Maintenance of a collaborative memory as an organizational knowledge base
6. Service-oriented architectures for collaborative automation.

Fig. 88.5 Collaborative e-Work: foundations, dimensions, and scope (after [88.3])

Examples of these developments are discussed in manufacturing and supply [88.12], in shared understanding for collaborative control [88.13], and in multirobot remote activation with collaborative control [88.14].

The "e" in collaborative e-Work is supported by the continuous creation of knowledge in four areas and their overlaps: (1) e-Work, (2) integration, coordination and collaboration, (3) distributed decision support systems, and (4) active middleware, all of which in turn are rooted in 15 e-Dimensions as described below (Fig. 88.5).

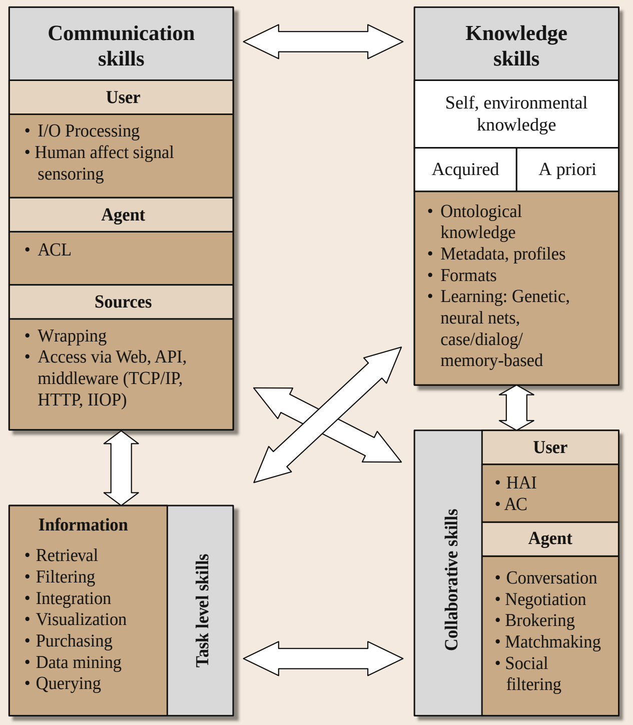
The first theoretical foundation area is *e-Work* itself, and it comprises four e-Dimensions: (1) e-Work theory and models, (2) agents, (3) protocols, and (4) workflow, as described below.

88.2.1 e-Work Theory and Models

Theory and models provide the foundation for the development of models to (1) augment human abilities and capabilities at work, (2) augment organizational abilities to accomplish their goals, and (3) augment the abilities of all organizational agents (e.g., human, computers, robots, etc.) for collaboration. Below, several principles that serve as guidelines and foundation for effective e-Work are discussed in more detail.

88.2.2 Agents

Agents are independently operating and executing programs capable of responding autonomously to expected or unexpected events [88.16]. Agents enable the automation and integration of flexible, adaptive, and heterogeneous activities, components, and tasks in a network. For instance, intelligent information agents are being used to (1) be proactive in the identification of enterprise resources, (2) provide value-added information for ongoing e-Activities, and (3) reduce the number of conflicts and errors in the information provided to and by all members of networked enterprises (Fig. 88.6). The applicability of agents expands a significant number of domains, including: autonomous mobile or stationary robots, electronic information systems, data mining and data clusters, decision-support systems, agent-based simulation, and intelligent design and manufacturing systems. An example of agents working in a collaborative environment includes the University of Michigan digital library (UMDL) where the library's electronic information and services are offered in a distributed environment by building on commerce and communication protocols for agent interaction.



ACL = Agent Communication Language; API = Application Programming Interface; TCP/IP = Transmission Control Protocol/Internet Protocol; HTTP = Hypertext Transfer Protocol; IIOP = Internet Inter-ORB Protocol; HAI = Human Agent Interaction; AC = Affecting Computing

Fig. 88.6 Agent-mediated trading: intelligent agents and e-Business (after [88.15])

88.2.3 Protocols

Protocols provide an efficient and effective platform for autonomous entities (such as agents) to interact, be productive, and achieve their goals. Many different types of coordination protocols have been designed to achieve effective coordination among agents, such as (1) dependence-based coordination between tasks [88.17, 18] and (2) decision- and time-based protocols to better meet requirement changes and complex scenarios that require decisions beyond coordination [88.19–21]. As an example, *Ko* and *Nof* [88.21] compare a task administration protocol (TAP) which is a coordination and interruption–continuation protocol (CICP), with a non-TAP coordination protocol (CP) to examine which protocol enables better assignment of tasks in a human–robot team under emergency pressures. They conclude that the performance of a TAP-based coordination protocol outperforms the non-TAP coordination protocol according to the ra-

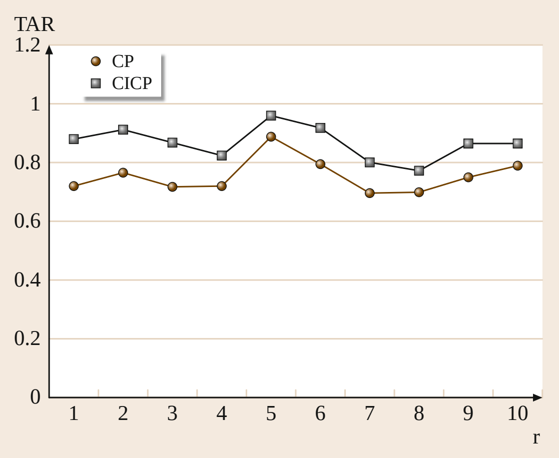


Fig. 88.7 Task allocation ratio (TAR) for emergency tasks [88.21]. The task administration protocol (CICP) always performs better because it is typically at a higher level of decision intelligence relative to the coordination protocol (CP)

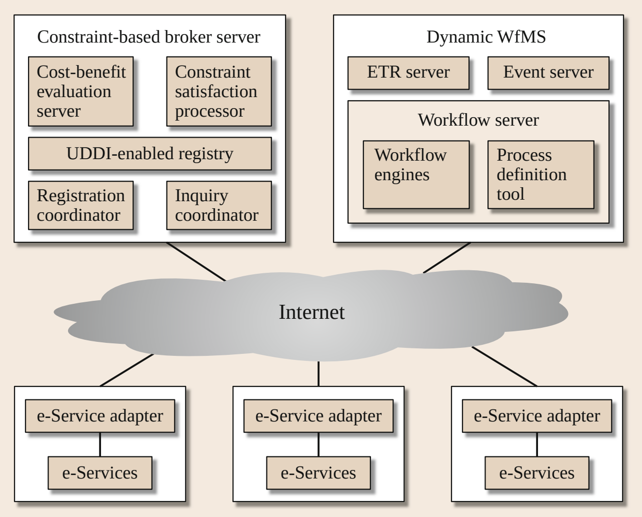
tio of total unallocated tasks to total number of allocated tasks (TAR) (Fig. 88.7). The protocols of interest in e-Work are those that function at the application level and which determine workflow control. Protocols at this level enable effective collaboration by coordinating information exchange and decisions such as resource allocation among production tasks to achieve a common goal and jointly generate better value. The unique advantage of TAPs is in smart e-Support and efficient, optimized streamlining of human collaboration.



UDDI = Universal Description Discovery and Integration

Fig. 88.8 Dynamic workflow management system (WfMS) architecture (after [88.22])

88.2.4 Workflow

Workflow captures the systematic assignment and processing of activities in dynamic, distributed environments by enabling process scalability, availability, and performance reliability. Workflow technology has received a lot of attention in recent years since it enables businesses to better manage information and operations. One recent effort has focused on the design and implementation of a dynamic workflow management system to support e-Businesses. The system developed allows for interenterprise workflow management using e-Services for a network of collaborating enterprises [88.22]. Due to the dynamics of the Internet and the organizations using it, an organization can join, leave or remain in a collaborative network without much difficulty; however, regardless of the decision of a given enterprise to join/leave or remain in a collaborative network of organizations, all scenarios require that existing data resources, processes, and services be integrated or interfaced via workflow models. Their model was the first attempt to develop a dynamic architecture to better account for the nature of services and their availability at different instances in time (Fig. 88.8).

The scope of the second theoretical foundation area includes *integration, coordination, and collaboration* and comprises four e-Dimensions: (1) integration, coordination, and collaboration theory and models, (2) computer-integrated manufacturing (CIM), (3) human–computer interaction (HCI), and (4) extended enterprises, as described below.

88.2.5 Integration

Integration, coordination, and collaboration theory and models provide the backbone for (1) identifying existing and new connections between information resources and processing entities/agents and (2) developing models and methodologies to enhance the collaborative activities between participating entities/agents and their use of information resources. Various approaches have been used to address the challenges of integration, coordination, and collaboration in the e-World. One of the best measures to assess the effects of a higher level of integration, collaboration, and cooperation is the number of areas being influenced, among them:

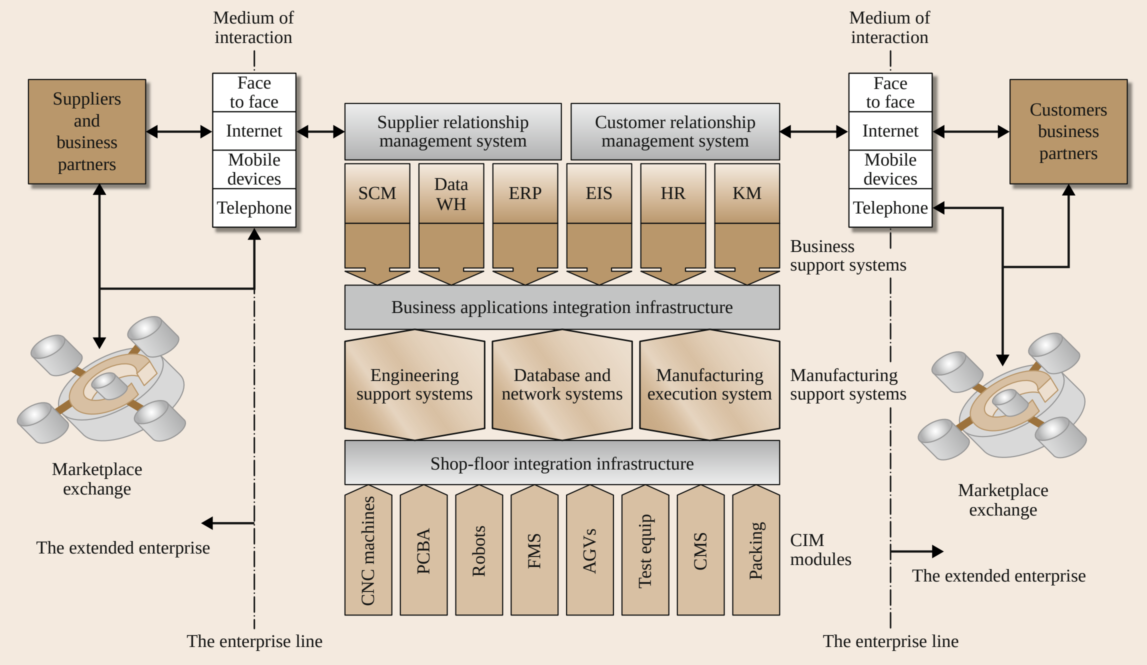
e-Business [88.23, 24], healthcare [88.25, 26], transportation [88.27], construction [88.28], and more.

88.2.6 Computer-Integrated Manufacturing

Computer-integrated manufacturing (CIM) enables the harmonized integration and management of the entire product lifecycle from design to customer service. Modern business is centered on intra- and intercollaboration processes, such as supply chain/network management, customer relationship management, employee–business integration, and more. To fully garner the benefits of this high level of collaboration, organizations need to implement integrated-enterprise systems. For instance, *Ho* and *Lin* [88.29] focus on the need for better collaboration throughout the complete business cycle and not just focusing on technical integration. In their work, they incorporate critical success factors (i. e., implementation strategy, change management, etc.) into the development of the different stages and components of an integrated-enterprise system (Fig. 88.9). *Choi* et al. [88.30] also develop an integrated enterprise architecture, but their focus is on virtual enterprise chains. Efforts such as these demonstrate the revolution that the collaborative enterprise world is experiencing with the evolution of collaborative e-Work principles, theories, and methodologies.

88.2.7 Human–Computer Interaction

Human–computer interaction (HCI) enables the development of systems, platforms, and interfaces that support humans in their roles as learners, workers, and researchers in computer environments. The majority of the work being conducted in HCI has focused on the methodologies and processes for developing interfaces, the design, implementation or evaluation of interfaces, and the development of theories and predictive models of interaction. As the roles of humans in today's workplace and society continue to evolve with the development of new technologies, so will the focal areas for HCI, among them ambient interfaces, affective computing, sensing interfaces, and tangible user interfaces [88.31]. For instance, in the work by *Altuntas* et al. [88.32], the authors present a formal approach to include a human material handler in a computer-integrated manufacturing (CIM) system.



FMS = Flexible Manufacturing Systems; SCM = Supply Chain Management; WH = Warehouse; ERP = Enterprise Resource Planning; EIS = Enterprise Information System; HR = Human Resources; KM = Knowledge Management; AGVs = Automated Guided Vehicles; CMS = Content Management System; PCBA = Printed Circuit Board Assembly

Fig. 88.9 The integrated enterprise system reference architecture (after [88.29] with permission from Taylor and Francis)

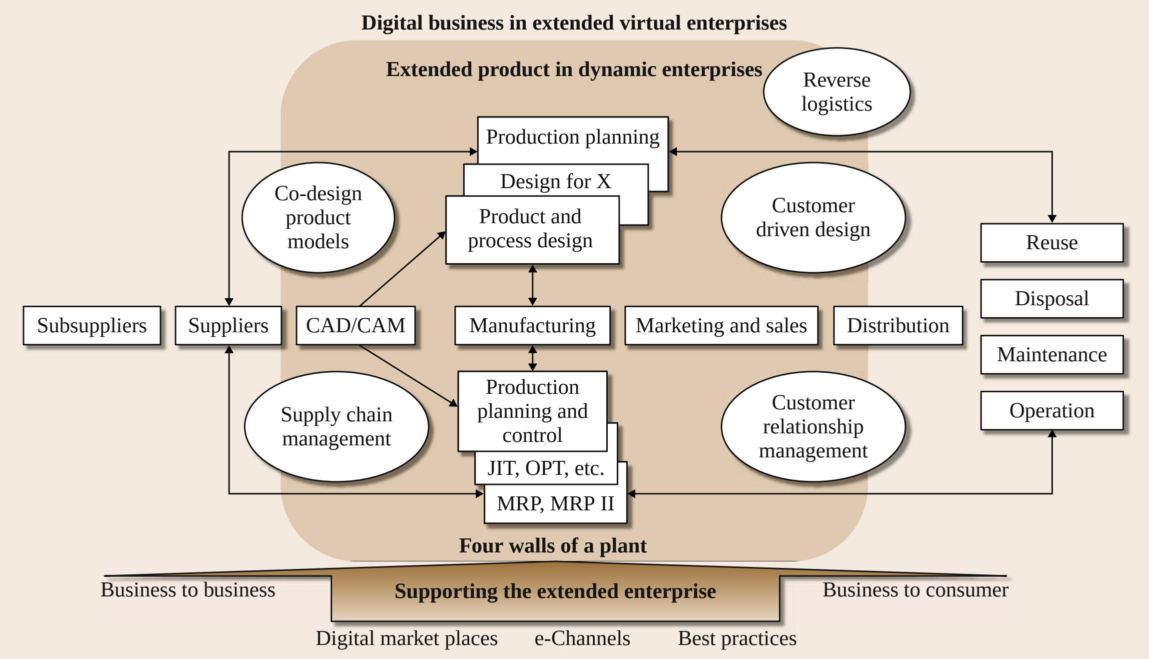
Fig. 88.10 Microsoft Surface (human–computer interface) for Sheraton Hotels (courtesy of Microsoft)

As the authors point out, most of the work in control has focused on automata-based methods for complex computer-controlled systems, whose application has been limited as the number of unmanned systems is relatively small.

HCI applications are starting to cross into the mainstream; for instance, Microsoft recently released Surface, an interface that enables users instant access to information and entertainment via their hands and gestures while improving collaboration and empowering consumers in the decision-making process (Fig. 88.10).

88.2.8 Extended Enterprises

Extended enterprises enable the creation of architectures, models, and methodologies to integrate business processes that go beyond the limits of a single enterprise and which include end-to-end functions, internal operations, and entire supply networks. The level of integration and connectivity of all value areas of supply networks has significantly increased with the advent of e-Business, e-Commerce, e-Services, and globalization. This trend has also increased the demand for new e-Work and e-Business applications and solutions to address the challenges faced when the world around us becomes an *e-World*. Figure 88.11 presents the transformation from traditional enterprises into extended enterprises, as defined by the extended products in dynamic enterprises (EXPIDE) project cluster from researchers of the European Information Society Technologies. The transformation of the enterprise serves as an example of the challenges and needs for the study and development of new methodologies, performance measures, and tools in the e-World.



JIT = Just in Time; MRP = Material Requirement Planning; CAD/CAM = Computer-aided Design/Computer-aided Manufacturing; OPT = Optimized Production Technology

Fig. 88.11 Extended products in dynamic enterprises (EXPIDE) architecture (after [88.2])

The third theoretical foundation area is *distributed decision support* and comprises three e-Dimensions: (1) decision models, (2) distributed control systems, and (3) collaborative problem-solving, as described below.

88.2.9 Decision Models

Decision models integrate computer tools and methodologies in the implementation of decision theories in online decision support systems, to provide more effective and better-quality decisions. The development and implementation of decision models to function in the *e*-world spans a wide spectrum. For instance, in e-Finance, one model called create–collect–manage–protect (CCMP) extends the finance framework from solely providing the technology perspective to one that better enables strategic decision-making by making use of enterprise application integration (EAI) with common object request broker architecture (CORBA) and web services to demonstrate the added value of using a network approach to the digitalization of financial and business content [88.34]. In a different application, fuzzy analytic hierarchy and fuzzy Delphi methodologies are used for multicriteria evaluation of e-Marketplace selection to deal with the uncertainty and vagueness of humans in group decision process, and therefore guarantee more effective decision making [88.35]. In a different application area, e-Manufacturing, an online quality information system (OQIS) using an object broker architecture along with a client–server enables its users both to obtain real-time data and information from any location and to address complex quality and deployment costs decisions (Fig. 88.12). The three examples of decision models described, along with their applications, highlight the influence and evolution of decision models needed in e-Business, e-Works and e-Service.

88.2.10 Distributed Control Systems

Distributed control systems empower systems with a greater degree of autonomy by enabling all parties (e.g., members of a supply network) to negotiate for the assignment/allocation of tasks and their respective

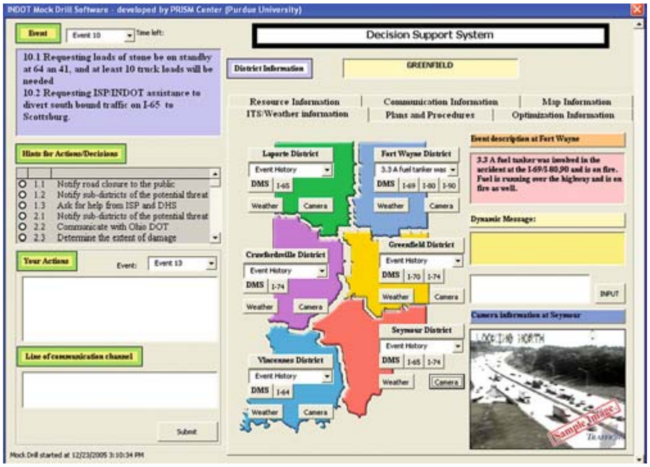
individual and group reward (incentives). Distributed control systems are common in manufacturing systems and in other processes in which the control is more effective and responsive when it is not located centrally but rather is distributed throughout the system, with local components being controlled by one or more controls. Typical examples of distributed systems include: electrical power grids and power plants (Fig. 88.13), water management systems, oil refining systems, sensor networks, pharmaceutical manufacturing, cement process (Fig. 88.14), and more.

88.2.11 Collaborative Problem-Solving

Collaborative problem-solving systems provide the necessary information exchange methodologies and models to influence parties (e.g., members of a supply network, or emergency response network, Fig. 88.15) in their decision-making processes so as to achieve harmonization, coherence in decisions, and better results (e.g., financial, customer service rankings) for all involved parties. For example, in the work by *Farand* et al. [88.37] the authors examine collaborative clinical problem-solving in the context of telemedicinal consultations in order to assess the degree to which the technological environment preserves medical reasoning under traditional settings. A theoretical framework and case study were implemented to measure the achievement of the goals defined. Another example in the medical field applies Bayesian networks to model individual student and group knowledge to better define problem-based learning (PBL) methodology for the teaching of clinical reasoning skills. The system developed, collaborative medical tutor (COMET), is an intelligent tutoring system for collaborative medical PBL [88.38].



INDOT Mock Drill Software - developed by PRISM Center (Purdue University)

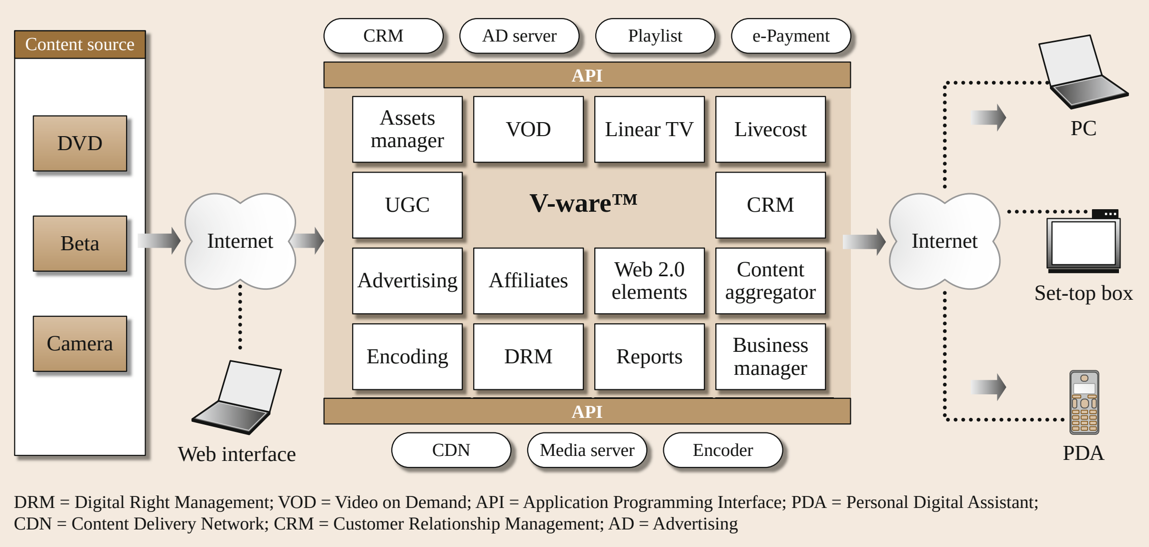
○ 1.3 Ask for help from ISP and DHS
○ 2.1 Notify sub-districts of the potential threat
○ 2.2 Communicate with Ohio DOT
○ 2.3 Determine the extent of damage

Event description at Fort Wayne: 3.3 A fuel tanker was involved in the accident at the I-69/I-80,90 and is on fire. Fuel is running over the highway and is on fire as well.

Mock Drill started at 12/23/2005 3:10:34 PM

Fig. 88.15 Mock/drill training interface for collaborative and distributed problem solving. The tool was designed to train transportation employees for emergency response. Trainees are able to interact with different users, see their actions, create their own action plans and decisions, request resources, and have access to a variety of organizational information needed to address the task at hand (after [88.36])

The fourth theoretical foundation area is *active middleware* and comprises four e-Dimensions: (1) middleware technology, (2) distributed knowledge systems, (3) grid computing, and (4) knowledge-based systems, as described below.



DRM = Digital Right Management; VOD = Video on Demand; API = Application Programming Interface; PDA = Personal Digital Assistant; CDN = Content Delivery Network; CRM = Customer Relationship Management; AD = Advertising

Fig. 88.16 v-Ware middleware architecture (printed with permission from Best TV Video Management Solutions)

88.2.12 Middleware

Middleware technology enables interoperability among distributed, heterogeneous applications, including legacy and advanced environments. Middleware is a layer of services or applications that provides the connectivity between the operating systems and network layers, and the application layer. For instance, in its basic operation, middleware enables the smooth connectivity and communication, and therefore functionality, between an older computer and a new scanner, printer or other peripheral components. In more advanced applications, middleware enables interoperability among more complex systems and networked organizations. Middleware is classified into the following categories of its e-Services according to the functions they provide: (1) distributed tuples which function as distributed relational databases, the most widely deployed middleware, (2) remote procedure call (RPC), which enables programmers to invoke a procedure across a network, (3) message-oriented middleware (MOM), which provides access to a message queue across a network, and (4) distributed object middleware, which provides the abstraction of an object that is remote but whose methods can be recalled just like those of an object in the same local address as the user. An example of a middleware technology concerning video applications is V-Ware, a middleware solution for online video services that supports video on demand (VoD), linear TV, user generated content (UGC), and live broadcasting, and is able to distribute it across diverse networks of TV, personal computers (PCs), and portable devices (Fig. 88.16).

88.2.13 Distributed Knowledge Systems

Distributed knowledge systems are a collection of autonomous knowledge-based objects sometimes also referred to as knowledge agents. In collaborative environments, agents (Sect. 88.2.2) interact with each other and work together to evolve the knowledge needed to improve decisions or solve queries, based on their respective abilities. In the work by *Ho* et al. [88.39] for instance, the authors develop a distributed knowledge model for knowledge management to support the development and implementation of enterprise systems involving information, system, and software-engineering technologies. The developed knowledge systems need to be updated because they are required to maintain high reliability, integrity, and quality of service for large-scale implementations.

Fig. 88.17 View inside a server tape Storateck in the computer center for the grid technology of the Large Hadron Collider (courtesy of CERN)

88.2.14 Grid Computing

Grid computing is a term that evolved in the mid 1990s to denote well-organized computing services that enable rapid sharing, selection, and aggregation of a wide variety of geographically distributed computing resources for solving large-scale and data-intensive computing applications. A computational grid provides dependable, pervasive, consistent, and inexpensive access to high-end computational resources [88.40] and enables its users to perceive heterogeneous resources as homogeneous. The creation of virtual (v-)environments (i. e., v-Factories, v-Organizations, etc.) requires the development of the necessary grid technology [88.41]. One application of grid technology that has garnered and will continue to capture people's attention is the Large Hadron Collider (LHC) at CERN, the European Organization for Nuclear Research. The LHC computing grid (LCG) will be one of the largest data-intensive applications in the world, combining and analyzing

data from the LHC detectors for over 10 000 scientists and over tens of thousands of computers around the world (Fig. 88.17). The computing grid will sift through petabytes (a million gigabytes) of particle collision data to uncover clues about the origins of the Universe.

From a business and service point of view, *Brocke* et al. [88.43] discuss the alignment of business needs of today's organizations and the availability of grid technology to better support virtual organizations. The authors argue that the collaborative reference model is a promising technique to enable the previously mentioned alignment by supporting distributed agents and the integration of technological, methodological, and organizational aspects.

88.2.15 Knowledge-Based Systems

Knowledge-based systems provide the capabilities to mine, refine, construct, and extract information from a variety of sources, enabling its transformation into knowledge capital. For instance, *Boughzala* [88.42] introduces the methodology for designing interenterprise cooperative information system (MeDICIS), an information system that models cooperative processes at three levels (communication, coordination, and collective problem-solving) in order to manage the knowledge available and generated by the cooperation. The development of MeDICIS highlights the existing interconnections between the many different dimensions of e-Work, as presented before, as it integrates, to name just a few (1) agents, (2) collaborative problem-solving, and (3) extended enterprises (Table 88.1).

88.3 Design Principles for Collaborative e-Work, e-Business, and e-Service

The flattening of the world [88.44] has significantly changed the ways in which business and commerce are conducted in the new world landscape. To a large extent, this has been enabled by automation, from communication and digital information exchange to extended supply and logistics networks, international transportation, and more. As a result of the flattening effect, work has become more distributed and decentralized and the magnitude and distribution of worldwide markets has significantly increased. These changes have brought opportunities for the development of better e-Work methods, augmentation of human physical, cognitive, temporal, and location abilities at work. However, just as the opportunities have expanded, so have the challenges and complexities associated with e-Work, particularly the scalability of workflow, information, and task overload. A number of projects that have attempted to understand and address these new requirements and challenges, and in turn develop useful theories and solutions, are summarized in Table 88.2.

88.3.1 e-Work Design Principles

The growing number of distributed and decentralized work systems over the last two decades has given e-Work the foundation for the exploration and development of new theories, models, and methodologies. The environment in which e-Work research has evolved has shown the complex needs and challenges that lie ahead for the effective development and implementation of e-Work. e-Work brings new and exciting opportunities for the definition of emerging and enhanced work methods and systems, as well as better outcomes and higher yields, by augmenting with e-Support the physical, cognitive, temporal, and locational human abilities. Research on collaborative e-Work, conducted at the Production, Robotics, and Integration Software for Manufacturing and Management (PRISM) Center at Purdue University to understand the needs and challenges, and develop appropriate theories, and solutions is highlighted in Table 88.2. In the table, many of the 15 dimensions introduced in Sect. 88.2 are addressed in various manufacturing, production, and service application domains. This research has been rooted in successful, proven principles and models of heterogeneous, autonomous, distributed, and parallel computing and communication.

Several collaborative e-Work design principles, which have emerged over the years as useful results of the collaborative control theory, are described in this section.

Principle of Cooperation Requirement Planning (CRP)

Originally developed by *Rajan* and *Nof* [88.45, 46], this principle considers collaboration as one of the most powerful augmentations of work abilities. Collaboration can be measured in a spectrum from minimal information sharing and exchange (implying a certain degree of cooperation) to fully integrated and collaborative enterprises. In order to achieve effective collaboration in any portion of the spectrum it is necessary to plan ahead. The *principle of cooperation requirement planning* includes two phases: (1) a detailed requirement plan of *who, how, and when* (CRP-I) is generated based on work objectives and available resources; (2) during execution, real-time implementation enables the revision of the plan to CRP-II, which meets spatial and temporal challenges, changes, and constraints. More recent work on this principle has included the integration of CRP with error diagnostics, recovery, and conflict resolution (Fig. 88.18) and the use of best-matching protocols for the identification and further implementation of *best policies* to address and correct errors and conflicts in robotic assembly and disassembly (Fig. 88.19). Future extensions will need to incorporate fuzzy logic and learning strategies (i. e., neural networks, genetic algorithms) to further enable real-time changes and learning. The effective implementation of this principle requires both advanced and adaptive real-time planning in order for the cooperation and collaboration efforts to be fruitful and efficient.

Principle of e-Work Parallelism

Originally developed by *Ceroni* and *Nof* [88.47, 48], this principle exploits the fact that work and interac-

tions in software and human workspaces can and must be allowed to run in parallel. To be effective, e-Work systems cannot be constrained by sequential (linear) tasks. In e-Work, the principle of workflow parallelism has deeper implications due to the distributed nature of the e-Activities and the fact that interactions take place over human and software spaces and can include (1) human–human interactions, (2) human–machine and human–computer interactions, and (3) machine–machine and computer–computer interactions.

Ceroni [88.47] defined the degree of parallelism (DOP) as the maximum level of resources and task parallelism necessary to balance the tradeoff between increased communication, transportation, and equipment costs and the increased productivity gained by the given level of parallelism. The authors developed the distributed planning of integrated execution method (DPIEM) as an effort to satisfy a CRP-based plan (Fig. 88.20). Among the issues explored in the planning was the ability to determine the optimal DOP, as seen in Fig. 88.21.

In addition to the definition of DOP, the *principle of e-Work parallelism* also addresses issues regarding the design and implementation of coordinated problem-solving and decision support that are of concern to the development of active middleware. The principle includes five guidelines to let e-Work support systems (EWSS):

1. Formulate, decompose, and allocate problems
2. Enable applications to communicate and interact under task administration protocols
3. Trigger and resynchronize independent agents to act coherently and cohesively in addressing problems, making decisions, and acting
4. Enable agents to reason, interact, and coordinate with other agents when needed
5. Develop conflict resolution, error recovery, and diagnostic and recovery strategies.

The *principle of e-Work parallelism* also influenced the development of co-X tools, where "co-" implies coordinated, cooperative, and/or collaborative support tools, e.g., co-design and co-plan [88.85]. These tools are defined at three levels of interaction: (1) sharing of information, ideas, and plans via an interface, (2) parallelism of information processing and physical tasks, and (3) inclusion of active protocols and agents to support parallelism.

Highly relevant to the *principle of e-Work parallelism* is the *keep it simple system* (KISS) design guideline. It states that, as long as a computer and communication-support system is enabled to work autonomously, in parallel to and support of humans at the simplest level for them, the system can be as complex as needed. The implications of KISS on the e-Work *parallelism principle* dictate that, in order to minimize the need for human retraining when new versions and advanced functions are incorporated into software systems, internal parallel e-Functions must be included in the design.

Principle of Conflict Resolution

Originally developed by *Huang* and *Nof* [88.49, 89], this principle addresses the cost of resolving conflicts among collaborating e-Workers. A greater rate of interactions, which increases the number of active collaborating parties, also increases the number of conflicts and errors that agents can incur. The development of effective e-Work therefore requires that errors and conflicts be overcome as quickly and inexpensively as possible. In their work, Huang and Nof observe that the total costs to resolve a conflict depend on the relative portion of human intervention as follows: (1) a greater number of errors and conflicts leads to an unbounded exponential growth of cost of resolution, which implies that the e-Work system will collapse due to the inefficiencies of the system, and (2) for less human intervention, approaching a value of zero (meaning that information technology (IT) services are designed to and applied in parallel), the total cost of resolution reaches an upper bound and can therefore be effective and sustainable (Fig. 88.18).

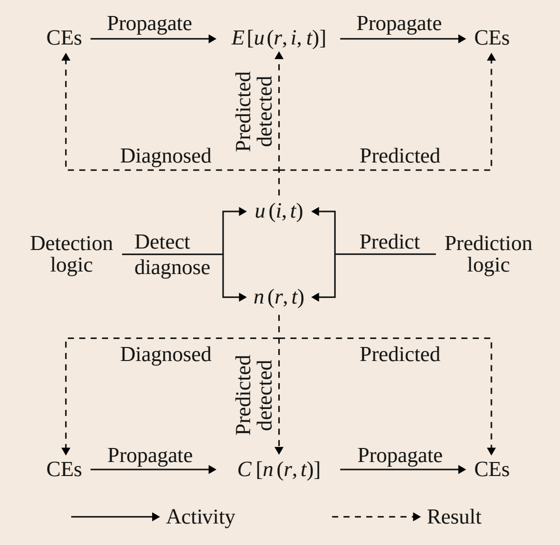

Fig. 88.22 Conflict and error diagnostics and prognostics (CEDP) logic over a coordination network (after [88.67])

The *principle of conflict resolution* requires the development of better and more powerful IT tools for detection, prevention, and resolution of errors and conflicts, which can yield lower overall costs, better quality, and more effective e-Work. Recent work has focused on the development of computer-supported conflict and error detection management (CEDM) and diagnostics and prognostics (CEDP) methods to eliminate errors and conflicts in robotic systems and supply networks [88.66, 67] as seen in Fig. 88.22. See also Chap. 30 (*Automating Error and Conflict Prognostics and Prevention*) in this handbook.

Principle of Collaborative Fault Tolerance

Originally developed by *Jeong* [88.71], this principle builds on the synergies between fault-tolerant collaborative control and feedforward collaborative control protocols to yield better, more effective results from teams of weaker agents (i. e., micro- and nanorobots, micro- and nanosensors) in comparison with a single optimized faultless agent (Figs. 88.23 and 88.24). The principle builds on the well-known fact that a collaborative team is better than the sum of the individuals, and it addresses how to achieve this advantage by using smart automation.

The Join/Leave/Remain (JLR) Principle in Collaborative Organizations

This principle addresses the increasing number of virtual enterprises and the dynamic nature of enterprise alliances, self-organizing agent teams, sensor clusters, modular systems, and others [88.94]. The principle enables the identification of conditions and timing for individual agents (parties) or organizations to join, leave or remain as part of a collaborative networked organization (CNO). Among the questions the principle addresses are:

1. When and why would an organization join a given CNO?
2. What are the benefits for an individual agent or organization to be part of a given CNO?
3. What are the costs for an individual agent or organization to participate (join or remain) in a given CNO?
4. Why would an individual agent or organization opt to remain in a given CNO?
5. What are the criteria and performance evaluation measures to characterize and assess the effectiveness and performance of the CNO?

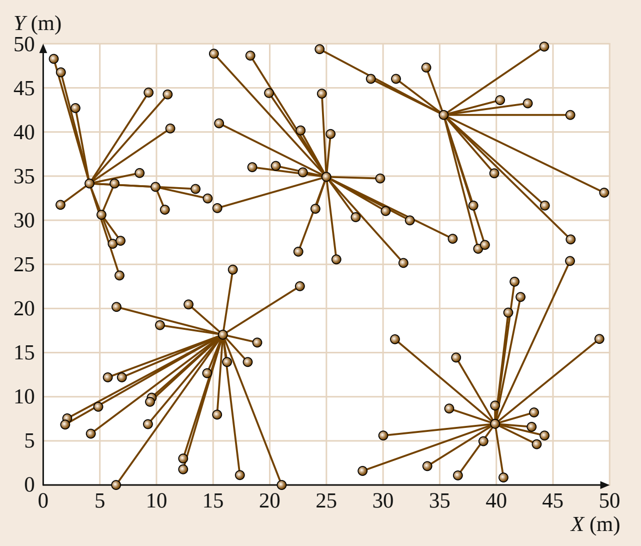

Fig. 88.23 Faulty sensor routed communication by time-based control. The *lines* between nodes represent communication links (after [88.93])

The *join/leave/remain principle* can be analyzed at different levels such as (1) overall CNO level, (2) individual agent or organization level, (3) sub-CNO, and (4) multi-CNOs, therefore making it adaptive and useful to address many types of agglutination and clustering of agents or organizations (Figs. 88.25 and 88.26). Furthermore, the analysis can be expanded to include each

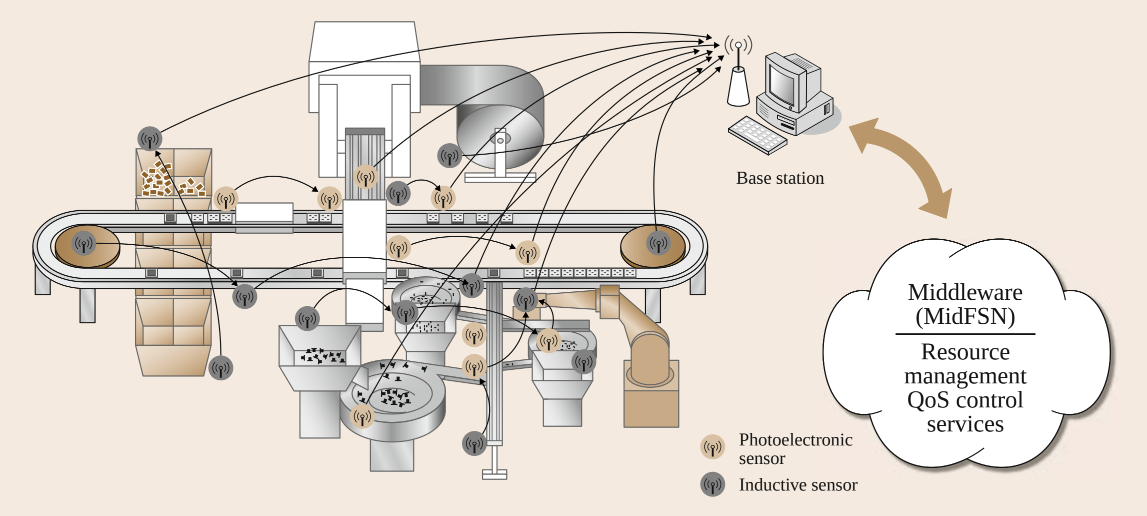

Fig. 88.24 Industrial application of a wireless microsensor network system with fault-tolerance capabilities (i. e., protocols) to aggregate weak sensor signals (after [88.54])

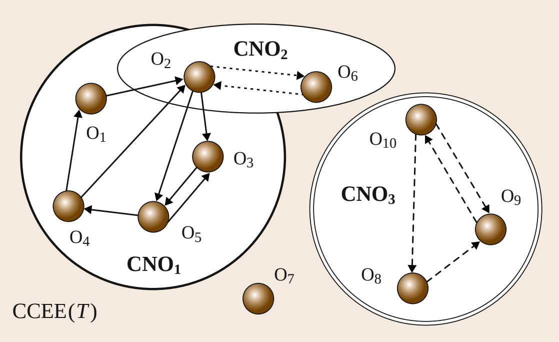

Fig. 88.25 Example of a collaborative networked organization (CNO) in a competitive environment at time T (after [88.77])

phase of the CNO life: creation, activity, dissolution, and support [88.77].

Principle of Emergent Lines of Collaboration and Command (LOCC)

The environment in which modern enterprises must conduct their day-to-day operations has become ever more challenging due to the dynamics of networks and the volatility of formal and informal communications within and between the members of the network, as well as with suppliers and customers. This principle focuses on three needs of organizations: (1) to have better collaborative decision-making, specifically under complex and dynamic events, (2) deliver information and build knowledge in a timely manner without being cost prohibitive, and (3) enable the development of emergent networks. Emergent networks are defined as evolutionary mechanisms of interaction which build upon the well-established theories of organizational learning and that are characterized by ad hoc decisions, effective improvisation, on-the-spot creation of contacts, and best-matching protocols for pairing system alerts with decisions, decision-makers, and the executors of the decisions (Figs. 88.27 and 88.28).

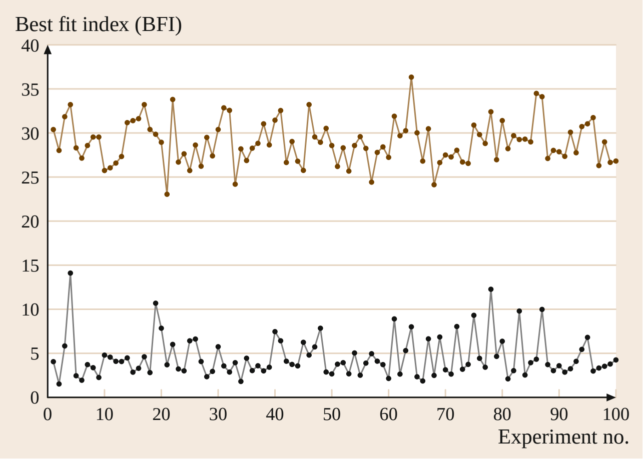

Fig. 88.27 Best-matching protocol (BMP) for the matching of 100 : 100 uniformly distributed parts in a manufacturing setting. The part-matching information is one of several factors then used to identify which supplier to match with a given customer

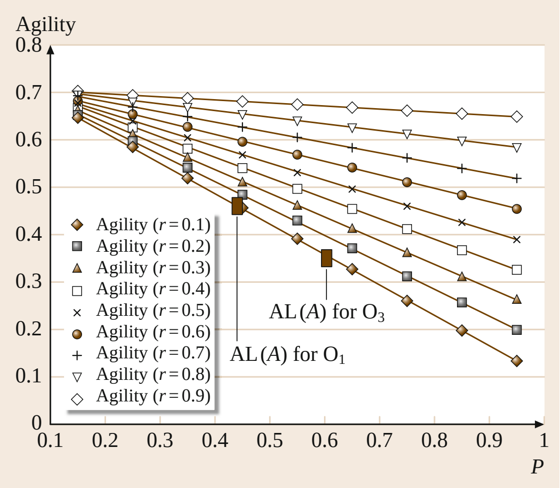

Fig. 88.26 CNO agility (A) under variable values for unexpected disturbance (P) and recovery (r) probabilities for a specific case (after [88.77])

The principle was originally developed by *Velásquez* and *Nof* [88.76] to enable organizations to answer the questions of (1) whom to contact, (2) under what circumstances to begin a contact, (3) when to contact, and (4) how to begin a contact under time pressure. A number of systems have already been developed which could be further enhanced by this collaborative e-Work principle. Examples are (1) SACHEM, which is a large-scale knowledge base for monitoring, alerting, and diagnosing dynamic processes in blast furnaces [88.95, 96], and (2) the public-health emergency response information system (PHERIS), which is a system developed to facilitate disease surveillance, command center for detection, collection of data and timely reporting, and resource planning and allocation for emergency response [88.97].

e-Measures: Criteria and Evaluation

With the advent of new work models, the need for new performance criteria and measures to assess the

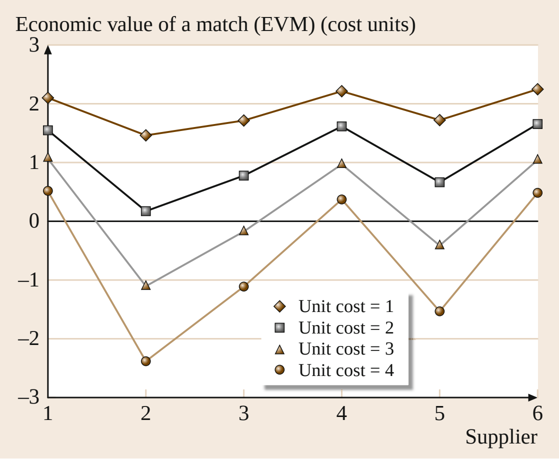

Fig. 88.28 Economic value of a match to identify which supplier out of six to match to a given customer according to the costs to manufacture and match parts (note: parts were generated following a normal distribution)

effectiveness of e-Work has increased. With the evolution of computer-integrated manufacturing (CIM) and networked enterprises, several measures have emerged, among them: flexibility, connectivity, agility (Fig. 88.29), integration ability, scalability, and reachability. Two recent performance measures developed at the PRISM Center are *viability* and *autonomy* [88.90]. *Viability* in the e-Work context has been defined as the ratio between operating and sustaining agents, and the rewards or benefits from their services. *Autonomy* implies the level of authority delegated and decentralization, and how active the agents, protocols, and other e-Work participants are. The development of new measures has not stopped and some of the emerging measures include: learning ability, collaboration ability, error and conflict detectability, error and conflict severity, and information significance.

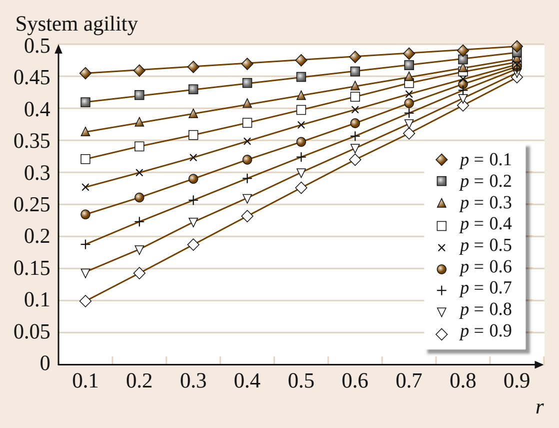

Fig. 88.29 System agility under various error probabilities p and recovery probabilities r (after [88.92])

The implications of the new measures of collaborative e-Work performance and characteristics have also been studied with the development of agent design and interaction theories. *Anussornnitisarn* [88.51] concludes that the performance of viability-based protocols exceeds that of protocols that did not take viability into consideration.

88.3.2 Emerging Collaborative e-Work, e-Business, and e-Service Design Principles

Bioinspired Collaborative Control

As the synergies between areas of research continue to evolve so will the theories and foundations of e-Work. In recent years, the biological sciences have started to influence collaborative control in e-Work, e-Business, and e-Service [88.98, 99]. Animal-to-animal interactions such as those observed among ants and bees have been adapted to enable the coordination of agents. The limited rationalizing capability of insects is enhanced by their ability to use pheromones as hints and therefore reduce information overloads. Similarly, in collaborative networks, the need to reduce complexity yet provide the appropriate *hints* to enable the agent to make a decision requires that only local and valuable information be shared by agents [88.100].

Bioinspired applications have included virtual insects (ants) as mobile software agents, message-based interactions among agents and robots, and measures such as viability (survivability) and autonomy (independence). Negotiation-based and bioinspired techniques are just two of the many useful techniques that have and will continue to influence multiagent collaborative control, as seen in Fig. 88.30.

Learning and Adaptation in Collaborative Control

Learning and other similar adaptive methodologies have played and will continue to play a critical role in automation and production/enterprise control. Genetic algorithms have been used, for instance, for the scheduling of complex products with multiple resource constraints and a multitier product structure (Fig. 88.31). The algorithms developed by *Pongcharoen*

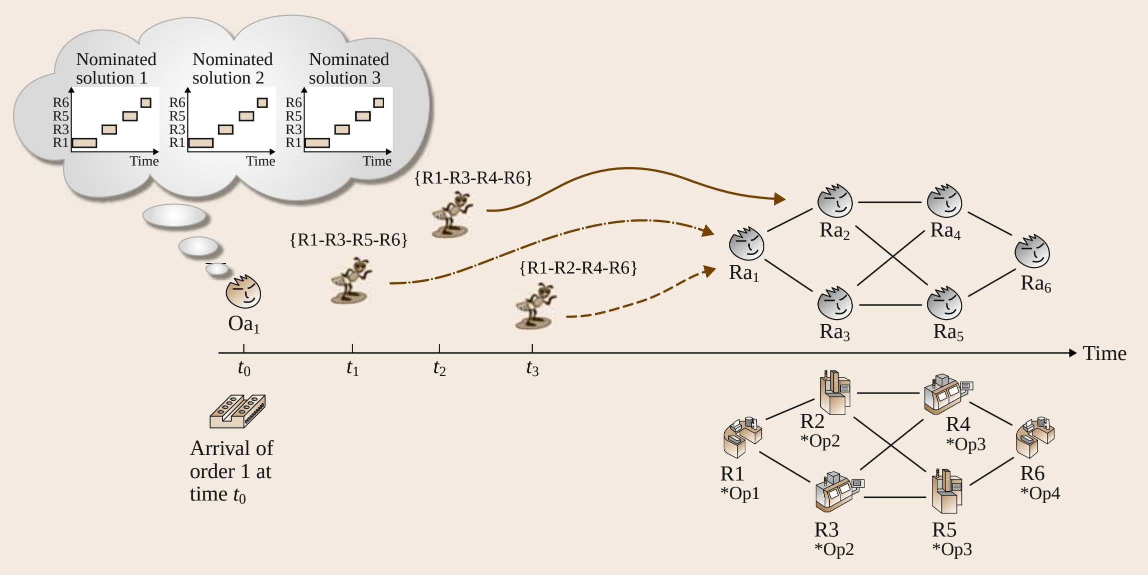

Fig. 88.30 Exploring mechanism of an ant agent in multiagent manufacturing control systems (after [88.102])

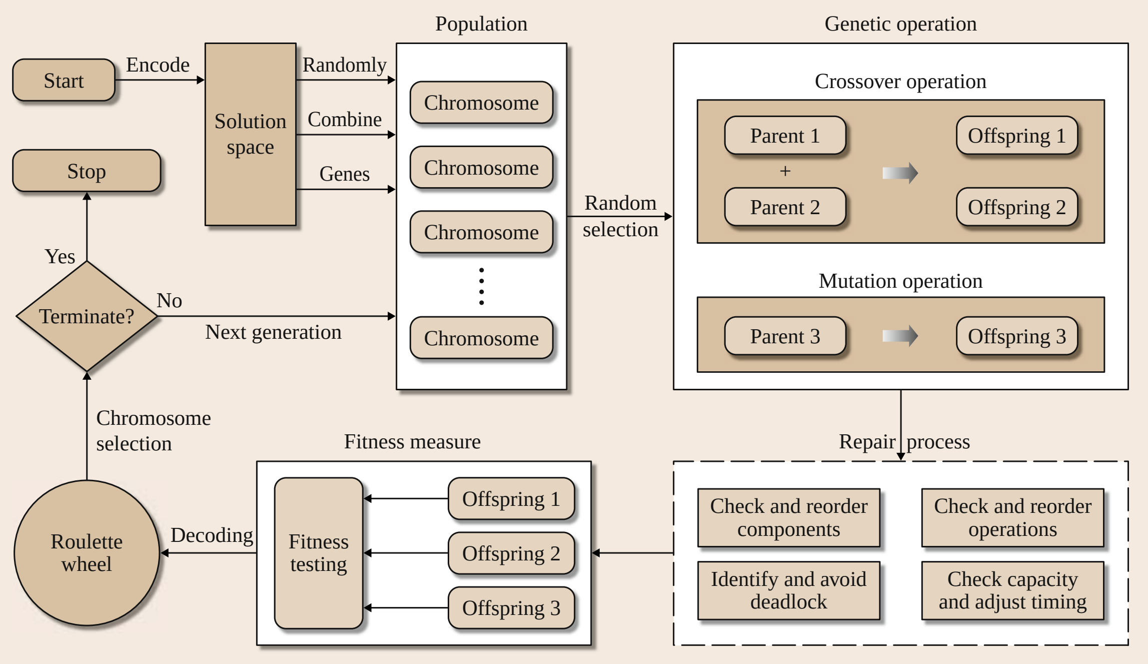

Fig. 88.31 Genetic algorithm structure for a production scheduling scenario (after [88.101] with permission from Elsevier)

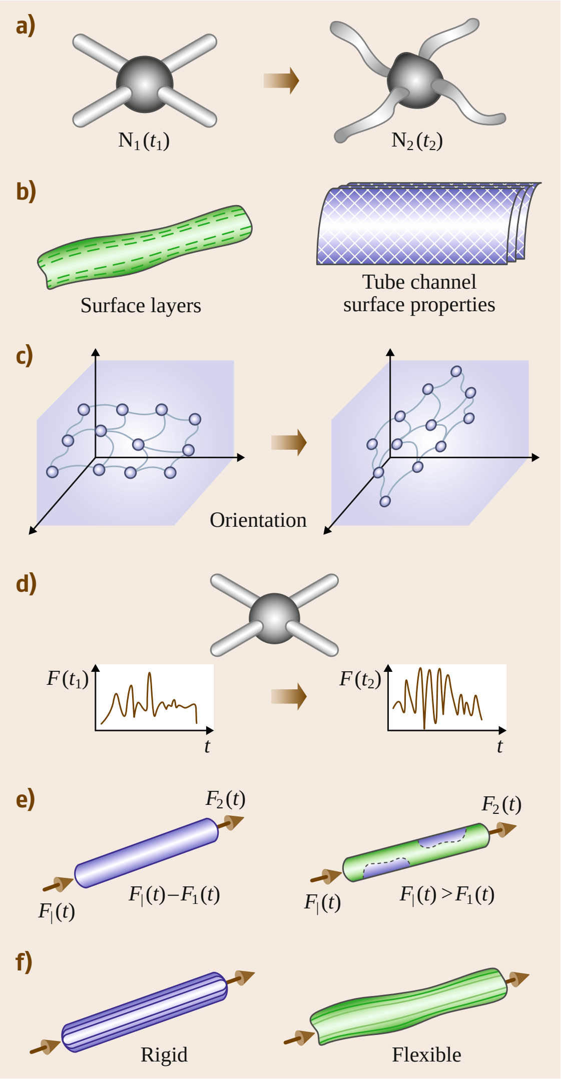
et al. [88.101] achieve on-time delivery and a 63% reduction in costs when compared with simulation results produced by a participating company.

In another work that involves decentralized and interactive learning, Lagrangian relaxation in combination with genetic algorithms was used to coordinate

Fig. 88.32a–f Bioinspired network models of e-Work, e-Service, and e-Business are developed. **(a)** Channels (arteries) modify their shape and plasticity over time; **(b)** the surface of channels changes dynamically and may have multiple internal layers; **(c)** changes over time in network spatial orientation; **(d)** time-variable electromagnetic channels waves as observed via nanowires in mice; **(e)** network learning: structural plasticity has a role in behavior – channel rigidity allows free flow versus channel blockages which constrict flow; **(f)** network learning: rigid versus flexible channels (after [88.9])▶



and optimize the production planning of independent partners linked by material flows in multitier supply chains [88.103]. Adaptation and learning are effective methodologies in market-based resource allocation to satisfy customer orders and needs [88.104, 105]. Studies at several laboratories around the world have found that adaptation by agents performs better at allocating and balancing resources and tasks.

Bioinspired Network Models

Recent work in biomembranes [88.106], neurology [88.107], and other areas reveals the potential of bioinspired mechanisms for adaptation, learning, and collaborative control. Just as synapses and spines collaborate to achieve survival and competitive animal behaviors, so can human-made enablers of collaborative control, such as adaptivity, dependability, discovery by data mining, decision support systems, and active middleware. The influence of biological collaborative control is still in its infancy and it is expected that new discoveries in these areas will lead to new models, theories, and solutions that satisfy the ever-growing needs of optimizing e-Work, e-Business and e-Service (Fig. 88.32).

88.4 Conclusions and Challenges

The methods by which humans, machines and computers interact and collaborate are rapidly being transformed in different areas of the economy, i. e., business, commerce, education, logistics, etc. Many of the benefits of e-Work, e-Business and e-Service have been the direct result of the automation of collaborative processes, activities and interactions that individuals and enterprises conduct in a day-to-day basis, among them:

1. *Error detection, reduction, and prevention*: the automation of processes enables enterprises to develop error mitigation and reduction strategies that guarantee better service, cost reduction, and faster response.
2. *Cost reduction of business and service processes*: the automation of business processes allows an enterprise to operate 24 h a day, 7 days a week without having employees work during some of the shifts,

therefore reducing labor expenses. In addition, operational savings on items such as business forms and office supplies also reduce the costs of business services.

3. *The ability to collaborate more effectively*: being able to access electronic business information and knowledge from anywhere, and anytime, has enabled enterprises to collaborate along the entire spectrum of the supply networks to provide all members of the network with just the information they need to work towards similar goals.
4. *Enhanced supply network management*: the automation of many of the business activities and processes that enterprises conduct has enabled the creation of more agile, flexible, and responsive networks, which in turn have led to the development of a more collaborative and responsive environment.
5. *Focus on added-value activities*: the automation of processes and activities has enabled enterprises to make better use of their resources (e.g., manpower, equipment) to reduce waste and idle time, and concentrate all their efforts on those tasks that contribute to the value of their products and services.

The future of collaborative e-Systems is promising and will require the exploration of different areas and the definition of further collaborative theories, principles, methodologies, and implementations:

- *Define and develop the foundation for collaborative control theory* to address many of the issues described in previous sections by finding synergies between existing control theories and other areas such as biological systems (see Chap. 75, *Robust Control in Biological Systems*).
- *Expand the breadth of investigation and implementation of collaborative e-Work principles and methodologies* to not only benefit and better enable large enterprises to compete and excel in the e-World but also small and medium-sized enterprises (SMEs). For example, in the book by *Corbitt* and *Al-Qirim* [88.108], studies on the implications of e-Business and e-Commerce principles to SMEs are summarized and their challenges are highlighted.
- *New ways of working and interacting in the e-World*. For instance, education in an e-enabled world (e-Learning and e-Training) requires the development of new skills, interfaces, teaching methods, and architectures so that activities such as e-Mentoring, e-Training, and others can yield the desired educational outcomes [88.109]. More information on e-Learning, e-Training, and serious games for teaching and learning can be found in Chaps. 85 (*Automation in Education/Learning Systems*) and 73 (*Automating Serious Games*), respectively.
- As organizations expand and become part of larger networks many questions regarding *optimal membership, clustering, and performance measures* (i. e., functional, economic, and quality) still remain to be addressed. Influenced by areas such as bioinspired networks, artificial intelligence, and bioinspired control, collaborative control will address these questions and move e-Work, e-Business, and e-Service into new frontiers.
- It is necessary to define and assess *new measures for production, service, and productivity* to better understand and improve the emerging *e-World* environment. Examples of such measures are collaboration-ability, recoverability, detectability, and more.

89. e-Commerce

Clyde W. Holsapple, Sharath Sasidharan

Electronic commerce (e-Commerce) is fast becoming a way of life in the 21st century. As more and more consumers and organizations resort to electronic means for conducting purchases and facilitating business transactions, it has become vital for academic researchers as well as practitioners to understand its workings, and be able to analyze problems and rectify weaknesses. This is complicated by the fact that the e-Commerce market is global and constantly evolving, with new and innovative business models and products being introduced at a rapid pace. We present an overview of the status of e-Commerce, with particular emphasis on academic research. Specifically, we review the historical background of e-Commerce, discuss theoretical frameworks, and examine e-Commerce models. We also discuss emerging trends as well as pressing issues facing the e-Commerce marketplace.

Electronic commerce (e-Commerce) is fast dominating every aspect of our day-to-day existence. Whether purchasing retail products ranging from books to automobiles, or services ranging from information to banking, consumers are increasingly turning to the Internet and the World Wide Web (WWW). Businesses are increasingly conducting transactions within their value chains and across their supply chains through electronic means. There is constant experimentation with newer and more innovative business models, resulting in an ever-evolving e-Commerce marketplace. This chapter provides a comprehensive picture of the e-Commerce landscape, with an emphasis on academic research findings.

With this in mind, we first discuss the evolution of e-Commerce. This is followed by a discussion of theoretical aspects of e-Commerce research: definitions, frameworks, and success parameters. We then discuss three broad e-Commerce models: business-to-consumer (B2C), business-to-business (B2B), and consumer-to-consumer (C2C). Special emphasis is given to three popular B2C activities: online shopping, online banking, and electronic learning. We then discuss three emerging e-Commerce applications: mobile commerce, telemedicine (or e-Health), and fee-based information delivery. Finally, we conclude with a discussion on two open issues facing e-Commerce: user trust and legal considerations.

89.1 Background

Prior to the 1960s, information systems (IS) were primarily used for scientific research and military purposes, and very rarely for commerce. The early business applications of computers ranged from the Lyons Electronic Office (LEO) system, automating clerical accounting tasks, to the Bank of America's electronic recording machine accounting (ERMA), involving the automation of check handling. The 1960s and 1970s saw business establishments becoming heavy users of computers for accounting and production activities, but largely confined to applications within the organization. It was with the development of the electronic data interchange (EDI) in the 1970s that organizations started communicating with one another electronically. The high cost of development and maintenance of private networks, lack of standardization, and the fact that not all organizations had EDI systems hindered its early growth. The development of the Accredited Standards Committee (ASC) X12 standards in the 1980s provided a boost to the popularity of EDI. Even today, EDI facilitates a majority of B2B e-Commerce transactions through value-added networks (VAN) and over the Internet [89.1, 2].

Paralleling the development of EDI was the growth of the Internet, which later (along with the World Wide Web) became the driving force behind B2C e-Commerce. The Internet had its origins in the late 1960s as the advanced research projects agency net (ARPANET), designed exclusively for research, education, and use by government organizations. Subsequently, in 1983, the ARPANET was split into the Milnet and the Internet, the former used for military purposes and the latter for research and education. Around this time, the communication of computers over the Internet was standardized using the transmission control protocol/Internet protocol (TCP/IP), and in the following year the domain name system (DNS) was introduced [89.3].

In 1989, Tim Berners-Lee of the European Laboratory for Particle Physics (CERN) started developing the World Wide Web (WWW). Commercial access to the Internet began with *The World*

(http://www.world.std.com) becoming the first provider of dial-up Internet access. Development of the Mosaic browser by Marc Andreessen, and its evolution into the Netscape browser with secure sockets layer (SSL) technology provided easy and secure access to the WWW for the general populace [89.3, 4].

In 1993, close to 30 million people were using the Internet in North America, with 43.2 million US households owning a computer. The subsequent years saw the launches of what were to become two of the greatest success stories in e-Commerce: Amazon and eBay, and the sale of airline tickets by Southwest Airlines through the WWW, marking the beginning of a new era in the travel and tourism industry. This was quickly followed by online travel sites sponsored by different airlines, and the emergence of online travel agents such as Expedia and Travelocity [89.2].

At this point, the primary limiting factor to the spread of e-Commerce was the speed, quality, and reliability of Internet access; however this issue was partially resolved with the introduction of the digital subscriber line (DSL). Worldwide, the number of Internet users had catapulted to 150 million, with more than half from the USA. In 1999, two of what were to become iconic names in cyberspace were launched: the search engine Google and the social networking website MySpace. The Google search engine provided a very efficient and effective search tool to browse the increasingly cluttered WWW, thereby indirectly promoting B2C e-Commerce activities (Fig. 89.1) [89.3, 4]. MySpace facilitated social networking through user-created personal profiles, blogs, groups, photos, and events.

The expansion of the Internet was also associated with the burgeoning B2B e-Commerce marketplace. New methods of conducting commercial transactions between buyers and suppliers along the entire length of the supply chain were developed. For example, in 1994, to improve material flow within their supply chains, the big three automakers, Chrysler, Ford, and GM, and 12 of their suppliers participated in the manufacturing assembly pilot (MAP) project. The MAP participants were electronically connected, and information took less than 2 weeks to reach the bottom of the supply chain, instead of the earlier 4–6 weeks. Another

Table 89.1 Important e-Commerce milestones

Year(s)	Event
1951	Lyons Electronic Office (LEO) system
1959	Electronic recording machine accounting (ERMA) system
1969	Advanced research projects agency net (ARPANET)
1970s	Electronic data interchange (EDI)
1971	Internet-based email
1982	ASC X12 standards for EDIs
1983	ARPANET was split into the Milnet and the Internet
1983	Transmission control protocol/Internet protocol (TCP/IP)
1984	Domain name system (DNS)
1989	World Wide Web
1989	*The World* (http://www.world.std.com)
1993	Mosaic browser
1994	Netscape browser
1994	Manufacturing assembly pilot (MAP) project
1995	Amazon and eBay
1996	Trading process network (TPN) post
1990s	Digital subscriber line (DSL)
1999	Google
2000	Bursting of the dot-com bubble
2004	B2B market size estimated at over US$ 1800 billion
2006	B2C market size estimated at over US$ 200 billion

case is that of General Electric (GE), which introduced its first online procurement system in 1996, an extranet called the trading process network (TPN) post. GE could now communicate with its internal customers over the extranet and with its worldwide suppliers over the Internet, facilitating same-day evaluation and award of bids [89.2].

The rapid development of the Internet in the late 1990s led to millions of dollars being invested in Internet-based online companies, leading to record-breaking stock value appreciation – the so-called *Internet bubble*. The year 2000 saw the bursting of the *bubble*, investment dropped, stock indexes plunged, and many online companies became defunct. The situation has since stabilized, and in 2006, B2C e-Commerce sales are estimated at over US$ 200 billion, an increase of 20% versus 2005. This, however, is dwarfed by the B2B market whose size amounted to US$ 1821 billion in 2004 [89.5, 6]. The important milestones in the evolution of e-Commerce are presented in Table 89.1.

89.2 Theory

Aside from its dynamic and still-unfolding history, e-Commerce has raised a host of questions related to its deployment, impacts, and possibilities [89.7]. To build a foundation for addressing these questions, researchers have investigated e-Commerce from a variety of standpoints, yielding a growing understanding of the nature and issues of this phenomenon that has emerged as such an important socioeconomic force. Here, we examine theoretical aspects of the e-Commerce research foundation from three perspectives: definitions, frameworks, and success parameters.

89.2.1 Definitions of e-Commerce

What is e-Commerce? What are its boundaries? What constitutes e-Commerce and what does not? As organizations devise new business models and innovative Internet-based applications, defining the boundaries of e-Commerce with any degree of precision has proven to be a challenge for researchers and practitioners alike.

For example, e-Commerce has been defined by researchers as [89.8]:

> . . . *the sharing of business information, maintaining of business relationships, and conducting of business transactions by means of telecommunications networks,*

and as [89.9]:

> . . . *the use of the internet to facilitate, execute, and process business transactions.*

Likewise, practitioners too have offered multiple definitions [89.10]:

> . . . *the buying and selling of goods and services on the internet, especially the WWW,*

and as [89.11]:

> . . . *the process of managing online financial transactions by individuals and companies.*

A review of these sample definitions makes it clear that there are multiple views or perspectives as to what constitutes e-Commerce. To provide an all-inclusive characterization of e-Commerce, *Holsapple* and *Singh* conducted an extensive study of the e-Commerce literature, and introduced a five-cluster taxonomy of e-Commerce definitions [89.12]. A common theme underlies definitions within each cluster. The five clusters are: the trading view, the information exchange view, the activity view, the effects view, and the value-chain view:

- The trading view is characterized by market-based activities such as buying and selling facilitated by electronic means. This is the most commonly held view of e-Commerce. *Holsapple* and *Singh* provide the following example as representative of the trading view [89.13]:

  > . . . *e-Commerce is associated with the buying and selling of information, products, and services via computer networks today and in the future via any one of the myriad of networks that make up the information superhighway.*

- The information exchange view recognizes the flow of information that can precede, accompany, or follow a transaction. A definition in this cluster may or may not mention the buying or selling aspects of a transaction. The following is an example [89.14, p. 136]:

> *Electronic commerce has been used to describe a wide variety of business related transactions, but is at its core the data used for conducting day-to-day business operations with suppliers and customers.*

- The activity view recognizes nontrading aspects of e-Commerce such as marketing and production activities, decision support, research, maintaining business relationships, and other ancillary activities [89.12, 15]. For example [89.16, p. 31]:

> *Electronic commerce is a generic term that encompasses numerous information technologies and services to improve business practices ranging from customer service to inter-corporation coordination.*

Together, the informational and activity views are emphasized in what is known as collaborative commerce (c-Commerce): the use of computer/communication technologies to help participants exchange information in the course of some collaborative activity, which may well enable the collaborative generation of new knowledge. c-Commerce has emerged as a major and growing facet of e-Commerce with a host of research issues in its own right [89.17].

- The effects view focuses on the goals or reasons for using e-Commerce, such as reduced costs, smoother information flows, remote collaboration, better coordination between buyers and suppliers, better customer management, and improved service quality. The following is an example [89.13, p. 1]:

> *Broadly defined, electronic commerce is a modern business methodology that addresses the needs of organizations, merchants, and consumers to cut costs while improving the quality of goods and services and increasing the speed of service delivery.*

- The value-chain view acknowledges the use of e-Commerce in creating value in one or more of the primary and/or secondary value chain activities of the organization. The value chain need not be intra-organizational, but can extend to interorganizational value chains of which the organization forms a part [89.12, 15]. The following is an example [89.18, p. 5]:

> *Electronic commerce denotes the seamless application of information and communication technology from its point of origin to its endpoint along the entire value chain of business processes conducted electronically and designed to enable the accomplishment of a business goal. These processes may be partial or complete and may encompass business-to-business as well as business-to-consumer and consumer-to-business transactions.*

Given the interconnectedness of five views, *Holsapple* and *Singh* advance an integrated definition of e-Commerce [89.12, p. 161]:

> *Electronic commerce is an approach to achieving business goals in which technology for information exchange enables or facilitates execution of activities in and across value chains as well as supporting decision making that underlies those activities.*

Although the integrated definition encompasses the taxonomy's five views of e-Commerce, it does not address the concept of information exchange to account for the whole gamut of knowledge management (KM) issues. Thus, *Holsapple* and *Singh* further extend this definition as follows [89.12, p. 164]:

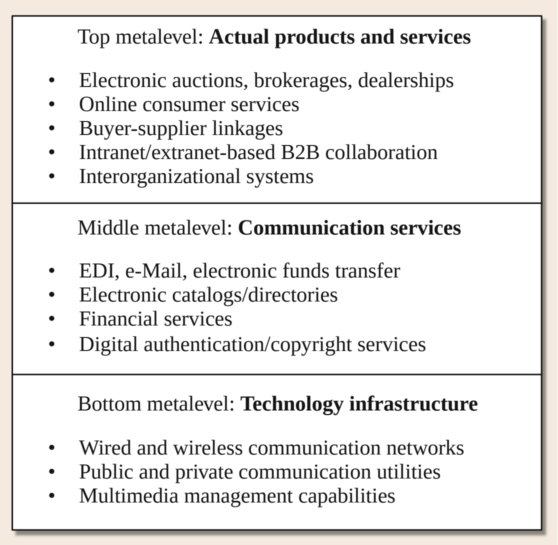
> *EC is an approach to achieving business goals in which technology is used to manage knowledge for purposes of enabling or facilitating the execution of activities in and across value chains as well as the making of decisions that underlie those activities.*

This is the most comprehensive definition of e-Commerce existing in the literature. A researcher, practitioner, or student can adopt any of the taxonomy's five views or the integrated comprehensive definition, but is well advised to be cognizant of the alternative views if the comprehensive definition is not adopted. Having considered e-Commerce definitions, we now summarize several frameworks proposed for appreciating e-Commerce elements and issues.

89.2.2 Frameworks for e-Commerce

The generic framework of electronic commerce, introduced by *Kalakota* and *Whinston*, identifies three major types of components: applications, infrastructure building blocks, and support pillars [89.13, 19]. Together, these form a basis for organizing one's thoughts about e-Commerce and for ensuring that important elements of e-Commerce are not overlooked. The first component, electronic commerce applications, includes systems for supply chain management, procurement, online marketing, remote banking, home shopping, and so forth. Underlying the applications, the second component is comprised of four layers of infrastructure building blocks. From lowest to highest, these layers are: the *information superhighway* infrastructure (the means for connecting, including the Internet), the network publishing infrastructure (the means for creation/storage of information and multimedia content, including servers), messaging and information distribution infrastructure (the means for moving content across connections and to/from storage, including email, EDI, file transfer, etc.), and common business services infrastructure (means for ensuring safety, reliability, and convenience of users, including mechanisms for authentication, security, privacy, paying, locating, and so forth). The generic framework identifies two support pillars for electronic commerce: public policy and legal issues (including regulation, taxation, cost, and policing concerns) and technical issues (including standards and protocols).

Alternatively, e-Commerce can be viewed as being comprised of three hierarchical metalevels: technology infrastructure, services, and products and structures (Fig. 89.2) [89.8, 20]. The bottom metalevel is the technology infrastructure and deals with wired and wireless communication networks, public and private communication utilities such as the Internet and organizational intranets/extranets, and multimedia management capabilities that deliver the functionality of the WWW. This metalevel corresponds to the lower layer of the generic framework's infrastructure building blocks. The middle metalevel is that of services, comprised of services facilitating secure communication and enablers such as electronic catalogs and directories, intelligent agents, electronic money and financial services, smart card systems, digital authentication services, and copyright services [89.20]. This metalevel corresponds to the higher layers of the generic framework's infrastructure building blocks. The top metalevel consists of the actual products and services as well as their delivery mechanisms. These include, among others, online consumer services for shopping, banking, and auctioning; buyer–supplier linkages and Intranet/extranet-based B2B collaboration; and other interorganizational systems that facilitate the entire spectrum of supply chain activities. This metalevel corresponds to the generic framework's applications component.



Top metalevel: **Actual products and services**

- Electronic auctions, brokerages, dealerships
- Online consumer services
- Buyer-supplier linkages
- Intranet/extranet-based B2B collaboration
- Interorganizational systems

Middle metalevel: **Communication services**

- EDI, e-Mail, electronic funds transfer
- Electronic catalogs/directories
- Financial services
- Digital authentication/copyright services

Bottom metalevel: **Technology infrastructure**

- Wired and wireless communication networks
- Public and private communication utilities
- Multimedia management capabilities

Fig. 89.2 Metalevel framework (after [89.8, 20])

Extending the hierarchical framework, *Zwass* proposes a *5C* activity framework that enables the identification of specific WWW-based e-Commerce innovational opportunities [89.21]. The *5C* activity framework recognizes five WWW based e-Commerce activity domains: commerce, collaboration, communication, connection, and computation. The commerce domain includes the marketplace and supply chain linkages. For the former, innovational opportunities are possible in searching for partners and subsequent negotiation of terms and conditions, new business models, product customization, delivery of products or services, and subsequent customer management services. For the latter, opportunities include redesign and reconfiguration of the supply chain, electronic reintermediation, and adoption of best-of-breed processes.

In the collaboration activity domain, the WWW can facilitate building and sustaining relationship networks such as long-term alliances between buyers and suppliers, and with customers. Innovations in the communication activity include the development of virtual customer communities that can serve to enhance knowledge of customer needs and requirements, obtain feedback of existing products and services, and form a source of new product ideas. In the connection domain, the anytime–anywhere connectivity provided by the WWW facilitates a wide variety of mobile commerce innovations for monitoring and tracking of personnel, objects, and systems. Movement of organizational information systems to the WWW can facilitate intra- and interorganizational system integration. The computation activity domain views the Internet and the WWW as a single enormous computing resource, connecting together innumerable computers, software, data, and people – facilitating grid computing.

Table 89.2 Riggins' electronic commerce value grid (after [89.22, p. 301])

Five dimensions	Value creation		
of commerce	Efficiency	Effectiveness	Strategic
Time	Accelerate user tasks	Eliminate information float	Establish 24 × 7 customer service
Distance	Improve scale to look large	Present single-gateway access	Achieve global presence
Relationships	Alter role of intermediaries	Engage in intermediaries micromarketing to look small	Create dependency to lock-in user
Interaction	Make use of extensive user feedback	User controls detail of information accessed	Users interact via online community
Product	Automate tasks using software agents	Provide online decision support tools	Bundle information, products, and services

To help managers identify online opportunities and types of applications that may yield value to users, *Riggins* describes a framework in which firms compete in a space defined by five dimensions of commerce: time, distance, relationships to customers, interaction modes, and product/service offered [89.22]. These are juxtaposed with three criteria for technology investment: greater efficiency, increased effectiveness, and strategic benefits. The result is the electronic commerce value grid, highlighting 15 areas for a firm to consider in striving to add value to its customers through web-based electronic storefronts (Table 89.2).

Choi et al. provide an integrated microeconomic framework for understanding electronic commerce and maximizing its benefits [89.23]. This framework characterizes e-Commerce as involving a global electronic marketplace of digital products subject to various pricing strategies. These products include online goods/services, software, digital content, advertisements, announcements, product/vendor information, digitized processes, payment/tracking information, smart products, communications, and so forth. Six major themes are stressed in this framework: product quality and the role of market intermediaries; digital copyright issues; product advertising; consumers' product-information searching activities; product evaluation/choice and pricing approaches; and digital financial services including payment processes. Each of these themes is subject to many design and implementation variations that demand attention from practitioners and deserve continuing investigation by researchers.

In a related vein, *Schlueter* and *Shaw* present a framework for analyzing structures and dynamics of digital goods/services markets and industries [89.24]. This framework identifies six value-adding stages for firms involved in e-Commerce: content direction, content packaging, market making, transport, delivery service, and interface and systems. Via alliances, mergers, or acquisitions, firms collaborate to align their capabilities and assets in ways that cover the six value-adding stages. This collaboration can involve diverse firms such as those in the financial service, information distribution, entertainment, creative content, communications, advertising, and computing industries. From another angle, *Lindemann* and *Schmidt* offer a market-oriented framework to model specific e-Commerce platforms for coordinating exchange activities among participants in digital markets [89.25]. Yet another e-Commerce framework integrates four earlier e-Commerce frameworks with the traditional marketing model (involving concepts of product, price, promotion, and distribution) as a foundation for devising e-Commerce marketing strategies [89.26].

The e-Commerce literature also contains a considerable number of fairly specialized frameworks. One of these, for example, advocates a three-level architecture for studying how intelligent agents can be applied to support electronic trading activities in the sense of making electronic markets more effective [89.27].

89.2.3 e-Commerce Success Parameters

What is meant by e-Commerce success? How can it be measured? Researchers have used multiple yardsticks for measuring e-Commerce success depending on the research context. For B2C transactions, widely used success parameters involve website usage factors such as acceptance, adoption, actual usage, intention to use, and intention to return [89.28–31], as well as purchase-related factors such as actual purchase, inten-

Table 89.3 B2C e-Commerce success parameters

Factors influencing success	Success measures
Website design factors:	**Website usage factors:**
● Navigation, convenience, usability	● Acceptance
● Reliability, responsiveness	● Adoption
● Accessibility, flexibility, relevance	● Actual usage
● Security/privacy	● Intention to use
● Quality of support services	● Intention to return
● Virtual-reality technologies for high-experiential products	**Purchase-related factors:**
● Social presence through rich descriptions and graphics	
● Value-added mechanisms	● Actual purchase
● Recommendations from prior customers	● Intention to purchase
	● Willingness to pay
Individual factors:	**Customer-related factors:**
● Demographics	
● Prior experience, computer self-efficacy	● Satisfaction
● Technological background	● Loyalty
● Subjective norms	● Learning
● Innovativeness, adaptability, awareness	
● Ease of use, usefulness, enjoyment	
● User trust	

tion to purchase, and willingness to pay [89.32–34]. Customer-related factors such as satisfaction [89.35], loyalty [89.36], and learning [89.37] have also been employed. Finally, customer perceptions of the usefulness of a website [89.38] and of the quality of a website [89.39] have been used to measure e-Commerce success. We summarize the e-Commerce success parameters in Table 89.3.

In order to bring clarity to e-Commerce research and to provide a framework for measuring e-Commerce success, *DeLone* and *McLean* suggest extending their information systems success model [89.9, 40, 41] to the context of e-Commerce research. The latter contends there are multiple dimensions of information systems (IS) implementation success including system usage (e.g., frequency, motivation, regularity, objectives of usage), system quality (e.g., reliability, response time, ease of use, usefulness, error rate), user satisfaction (e.g., overall satisfaction, decision-making satisfaction, user complaints), information quality (e.g., accuracy, precision, timeliness, completeness), service quality (e.g., assurance, empathy, responsiveness), and net benefits (e.g., productivity, decision accuracy, profit). Adapting these success dimensions to the e-Commerce domain, with suitable modifications, yields their framework for measuring e-Commerce success.

System usage in an e-Commerce context translates into the number of website visits, navigation within the site, and transaction execution. As noted above, most of these have already been widely used by researchers. For the system quality dimension, factors such as reliability, accessibility, response time, ease of use, and usefulness are extended directly to the context of a website, and these have been used in studies reported in the e-Commerce literature. The user satisfaction dimension can be applied to measure satisfaction at different stages of customer interaction, ranging from information gathering to post-purchase services. In the case of the information quality dimension, an important factor is privacy and security, apart from personalization of content, and the completeness and relevance of the information. Service quality can be measured as the overall customer experience, and this is an important measure given the fact that switching costs are low in an e-Commerce environment. Net benefits in an e-Commerce environment can be measured in terms of savings in time and money, enhanced productivity, and improved decision-making [89.9].

89.3 e-Commerce Models and Applications

The US Department of Commerce views B2B e-Commerce as dealing with manufacturing and wholesale activity, and B2C e-Commerce as dealing with retailing and the service industry [89.6]. Based on this categorization, the total volume of e-Commerce transactions in 2004 amounted to US$ 1951 billion, representing a 14.4% increase over the previous year, and comprising roughly 10% of the total value of US shipment, sales, and revenue. The lion's share of the e-Commerce market in dollar terms is in the B2B segment, amounting to 93% or US$ 1821 billion. However, given its intrusion into virtually every single aspect of our daily life, B2C e-Commerce remains perhaps the most visible and easily recognizable face of e-Commerce. We first discuss the B2C e-Commerce market, followed by the B2B e-Commerce market. We then discuss the small but rapidly emerging C2C e-Commerce market.

89.3.1 B2C e-Commerce

The B2C e-Commerce market has continued to grow with recent estimates being as high as US$ 210 billion for 2006, an increase of 20% over the previous year, and projected to reach US$ 330 billion in 2010 with an estimated 55 million online shopping households in the US. In dollar terms, the largest B2C e-Commerce product line is travel, with approximately 35% of the market at US$ 70 billion. This is followed by computer hardware and software at US$ 17 billion, automotive equipment at US$ 16 billion, and apparel at US$ 14 billion [89.5]. We now examine some of the more important segments of the B2C e-Commerce marketplace: online retail shopping, online banking, and electronic learning.

Online Retail Shopping

This is perhaps the most visible face of e-Commerce – the online selling of a wide range of retail goods and products such as clothing, clothing accessories, electronic devices, electrical appliances, computer hardware and software, books and magazines, food and beverages, health and personal care items, sporting goods, music and videos, and office equipment and supplies. Apart from retail goods, the major services sold online include those related to computer systems, publishing, securities and commodity contract intermediation/brokerage, and travel arrangement/reservation. In recent years, retail e-Commerce sales registered an annual growth of 25% compared with 4% for total retail sales; however, it still is only a small fraction of total retail sales, at around 2% in 2004 [89.6]. Interestingly, two of the product lines projected to experience the highest market growth are cosmetics and pet supplies [89.5].

Based on Internet traffic rankings, the most popular online shopping site is Amazon (Fig. 89.3) having a global reach of around 1.8% of measured Internet users [89.42]. With annual revenues of US$ 10.7 billion in 2006, this Fortune 500 company lists thousands of new and used items at its website, spanning the entire retail product spectrum. Apart from the wide array of products, Amazon incorporates a number of personalization features such as one-click buying, customer and editorial product reviews, gift registries and certificates, wish lists, and restaurant and movie listings. Other major online shopping sites include those of Target, Wal-Mart, Best Buy, New Egg, and Tiger Direct.

What are the factors that influence the adoption of online shopping by consumers? Research has indicated that the design of the website in terms of navigation, convenience, usability, reliability, responsiveness, security and privacy, as well as the quality of support services such as order fulfillment, help desks, and return policies affect user adoption [89.33, 35]. The website should be attractive and have a social presence through rich descriptions and graphics, particularly in the case of products having amusement value [89.43]. The use of virtual-reality technologies serves to minimize the problems associated with the user being unable to touch and feel the product. This is particularly true in the case of high-experiential products where customers need to learn more about the product and experiment with it before making the purchase [89.37]. Also, a badly styled, incomplete, and erroneous website results in a negative impression regarding the quality of an online store, and the resulting lack of trust drives customers away from the store [89.39, 44].

Online stores that provide value-added mechanisms such as search engines serve to enhance shopping enjoyment, particularly for customers who are not looking to purchase a specific product [89.28]. Positive recommendations from prior customers via a consumer-reputation facility serve to reduce decision-making time and enable customers to make better decisions [89.38]. Above all, the most important factor that could make or break adoption of an online shopping site is customer perception of trust in the online shopping merchant [89.35, 39, 45]. As this aspect is relevant in all segments of

e-Commerce, we deal with it separately in a subsequent section.

Online Banking

Online banking is one of the fastest growing Internet activities with about 43% of Internet users (63 million adults) banking online on a regular basis [89.46]. It has been estimated that the average total assets of an Internet-only bank is US$ 3.5 billion compared with US$ 1 billion for all banks [89.47]. Currently, online banking portals provide an array of services to customers including typical banking activities such as transferring funds, advancing loans, ordering checks, and downloading information about checking/savings, interest/dividends, loan payoffs/balances, and share/checking balances. Based on Internet traffic rankings, the most popular US banking site is that of the Chase Bank (Fig. 89.4), having a global reach of around 0.02% of measured Internet users [89.42]. Other major players include Bank of America, Citibank, US Bank, and Wachovia Bank.

What are the important factors that influence customer adoption of online banking? These fall into two broad categories: individual characteristics and user perceptions of the online banking website. In the former category, factors include demographics related to income, age, and gender, prior computer experience, computer self-efficacy, technological background, subjective norms, innovativeness, adaptability, and awareness of online banking benefits [89.29, 48, 49]. In the latter category, factors include usefulness, enjoyment, usability, convenience, accessibility, and relevance of the website [89.29, 50].

Although the size and growth of online banking has been impressive, it has not outpaced the growth of the Internet or other e-Commerce activities due to the *trust gap* [89.46]. Despite the technical advancements that have led to the safe and secure transmission of sensitive information, a sizable portion of Internet users still have reservations regarding the security and confidentiality of online banking transactions, and hence do not trust online banking sites [89.30, 45]. The trust barriers could be overcome by incorporating privacy and data protection technology into banking website design, proper authentication of users, informing users regarding secure online banking practices, and provid-

ing redressal mechanisms [89.29,30]. Indeed, trust is an issue that is of concern not only for online banking, but for e-Commerce as a whole, and is dealt with in a subsequent section. See Chap. 91 for additional content on automation in financial services.

Electronic Learning

Electronic learning, or e-Learning, is one of the fastest growing segments in the B2C e-Commerce domain. It primarily consists of the delivery of educational content to individuals or groups of learners via the Internet and WWW, as well as through organizational intranets and extranets [89.51]. Perhaps the most pervasive form of e-Learning is distance education, wherein universities provide online course content and teaching to students on a global basis. In addition, business organizations use electronic learning for employee training, certification, and upgrading skills, so much so that the corporate e-Learning market is estimated to be nearly US$ 10.6 billion in 2007 [89.52]. Currently, the major players include WebCT and Blackboard (Fig. 89.5), Desire2Learn, Dokeos, Skill Soft, Epic, and Learning Steps.

What factors influence the success of e-Learning? The e-Learning success model posits that the overall success of an e-Learning initiative depends on attaining success at every one of three stages of e-Learning system development: design, delivery, and outcome [89.53]. An empirical study supports the model and finds that action research methodology can be instrumental in promoting the development of successful e-Learning systems by iterating through cycles of diagnosing, action planning, action taking, evaluating, and reflecting.

Due to relatively little (or no) face-to-face interactions with an instructor, an electronic learning program may not provide the same amount of instructor guidance as opposed to a conventional classroom teaching or employee training session. Given this, an important factor that can influence effective use of an electronic learning program is self-regulation – the capability of an individual to take charge of his/her learning path. Self-regulation requires time-management skills, self-motivation, an ability to set and meet performance goals, and an ability to effectively organize, rehearse, and encode information [89.54–56].

Fig. 89.5 Blackboard website

Apart from individual characteristics, technological features of an e-Learning system, such as its quality and reliability, availability, flexibility, convenience, and level of interactivity, can influence its adoption [89.57, 58]. If a human instructor is part of an electronic learning system, care must be taken to ensure that his/her presence is felt frequently in the online environment, providing timely, detailed directions, and making extra efforts to reach out to and interact with users [89.57,59]. Also recommended is matching the technology with the nature of the course content, thus courses that need creative thinking would be better served with technology having higher degrees of interactivity than courses that can be learned by rote [89.54]. See also Chap. 73, *Automating Serious Games*, and Chap. 85, *Automation in Education/Learning Systems*, for related content on electronic learning.

89.3.2 B2B e-Commerce

With a value of US$ 1821 billion in 2004, the B2B e-Commerce market dwarfs the B2C segment. It comprises 93% of the e-Commerce market, and approximately 20% of the overall B2B market [89.6]. Major areas of concentration include food, textiles, petroleum, chemicals, machinery, computers and electronics, automotive, paper, and pharmaceuticals. We now discuss various B2B market mechanisms with the help of examples.

B2B transactions can be categorized based on the actual mechanisms that are required to execute the transaction. These in turn can be categorized based on connectivity and purpose. The former refers to the number of players (i. e., buyers and suppliers) involved in a transaction, and the latter refers to the intention of the player initiating the B2B transaction [89.60]. The number of players involved in a B2B transaction may be one-to-one, one-to-many, many-to-many, and any-to-any. The common example of one-to-one is via an extranet, where a buyer interacts with a particular seller. An example of one-to-many connectivity would be an auction, where the seller puts up a product for bidding, and potential buyers bid for the product until the final price is reached. A corollary of the one-to-many category would be the many-to-one, or the reverse auction, wherein mul-

Table 89.4 *Cullen* and *Webster* B2B e-Commerce model (after [89.60])

Category	Connectivity	Purpose	Technology	Interaction
Individual trading	Open	Selling	WWW	Direct
Collaboration	Open	Selling	WWW	Intermediary
Marketplace	Open	Selling/buying	WWW	Intermediary
Proprietary sales	Restricted	Selling/integrated	Extranet	Direct
Private exchange	Restricted	Integrated	Extranet	Intermediary
Aggregation	Open	Buying	WWW	Intermediary
Intranet/EDI	Restricted	Integrated	Intranet/EDI	Direct
Restricted bid	Restricted	Buying	Extranet	Direct
Reverse auction	Open	Buying	WWW	Direct

tiple sellers quote among themselves and the lowest quote is accepted. The many-to-many scenario involves multiple buyers and sellers, wherein each could form alliances resulting in buyer and seller organizations. They could interact through a neutral exchange platform provided by an intermediary where the requirements of the buyers and sellers could be matched. In the any-to-any scenario, there could be one or many sellers or buyers, an example being e-Hubs hosting electronic marketplaces that facilitate interaction between buyer(s) and seller(s) [89.60–62]. Connectivity may also be viewed as open or restricted/closed. Open transactions can be accessed by all players involved whereas restricted/closed transactions are limited to specific players, generally those having membership privileges [89.60,61]. The purpose of engaging in a B2B transaction may be for selling, buying, or integrated exchange. The last includes multidimensional activities such as exchange of commercial documentation or operational information.

The concept of connectivity and purpose can be extended to include aspects such as the facilitating technology and the interaction type [89.60]. Examples of facilitating technologies are the WWW, extranet, Intranet, and EDI. Interaction may be direct between the buyer and the seller, or may involve an intermediary, wherein a third party mediates the transaction. Based on connectivity, purpose, technology, and interaction type, the *Cullen* and *Webster* model categorizes e-Commerce transactions into nine operational categories: individual trading, collaboration, marketplace, proprietary sales, private exchange, aggregation, intranet/EDI, restricted bid, and reverse auction (Table 89.4) [89.60].

Individual Trading

This type of transaction has open connectivity, involves selling, uses the WWW, and is direct. The typical example is a single supplier selling to other business organizations. This model is very common in the maintenance, repair, and operations (MRO) industry. An example is Grainger, which provides access to more than 800 000 products from such categories as adhesives, fasteners, hardware, lighting, motors, power transmission, and hydraulics [89.63].

Collaboration

This category is viewed as being open, involves selling, uses the WWW, and involves an intermediary. As opposed to individual trading, collaboration involves multiple organizations that converge onto a common platform run by an intermediary organization. These are common in the pharmaceutical, chemical, and motor industries. For example, in February 2000, major automakers collaborated to create Covisint [89.64], to address escalating procurement costs and inefficiencies within the industry. Covisint currently supports over 30 000 organizations in the global automotive industry spread across 96 countries and having over 266 000 users. See Chap. 88 on *Collaborative e-Work, e-Business, and e-Service* for a more thorough collaboration discussion.

Marketplace

The marketplace category is open, involves both selling and buying, uses the WWW, and involves an intermediary. The intermediary provides a common platform for buyers and sellers to sell commodity and standardized products. An example is ChemConnect [89.65] which provides a third-party commodity exchange platform for the chemical industry [89.60].

Proprietary Sales

This category of B2B transactions tends to be restricted, involves selling and integrated exchange, uses an extranet, and is direct without involving an intermediary. It mainly involves the sale of sensitive goods such as military equipment, prescription medicines, firearms, and the like. To engage in a proprietary sales transaction, the buyer or seller must posses some form of membership, certification, or clearance from a government agency. Cullen and Webster point to Wolverine Supplies [89.66], which provides firearms to law enforcement officers in Canada as representative of this category.

Private Exchange

This category is restricted, involves integrated exchange, uses an extranet, and involves an intermediary. The typical example here is the case where a buyer organization has long-term supply-chain relationships with supplier organizations. Cullen and Webster cite the example of Elemica [89.67], which provides a platform for a range of integrated supply-chain activities in the chemical industry.

Aggregation

The aggregation category is open, involves buying, uses the WWW, and involves an intermediary. Here, smaller buyer organizations group together to negotiate with a seller organization so as to obtain economies of scale that they would not otherwise have obtained. Powerspring [89.68], a third-party intermediary in the power industry that provides a platform for gas suppliers to bid competitively for aggregated power demand, is representative of this category [89.60].

Intranet/EDI

This category is restricted, involves exchange of trading information, uses intranet/EDI, and is direct. Transactions are typically one-to-one between the buyer and seller, and are typically conducted by large organizations having a number of repeat orders.

Restricted Bid

As the name indicates, the restricted bid category is restricted, involves buying, uses the extranet, and is direct. Only a limited number of selected suppliers are allowed to bid for a product required by the buyer, resulting mainly in time savings. The National Health Services in the UK uses this approach in procuring some of its supplies [89.60].

Reverse Auction

The reverse auction is open, involves buying, uses the WWW, and is direct. For example, XSAg [89.69] provides a reverse auction in the agricultural chemical industry. The buyer lists the product requirements including the asking price and quantity on the XSAg website, and potential sellers bid for the business. Suppliers that meet the asking price and other buyer requirements win the contract immediately upon bidding. The federal government also uses reverse auctions, through dozens of federal organizations such as the General Services Administration, the Department of Homeland Security, the Department of State, and the Department of Defense [89.70].

89.3.3 C2C e-Commerce

The consumer-to-consumer (C2C) e-Commerce market is dominated by online customer auctions, wherein auction providers act as intermediaries providing a common platform for buyers and sellers to engage in the selling and purchase of retail goods. With US$ 15 billion in sales in 2004 [89.71], the size of the C2C online auction market is minuscule compared with the B2C and B2B markets; however it has spawned one of the greatest success stories of e-Commerce: eBay (Fig. 89.6). Apart from eBay, the other major player in this area is Ubid [89.72].

Auctions may be seller auctions or buyer auctions; in the former the seller initiates the transaction by listing an item for sale, and in the latter the buyer initiates the transaction by posting purchase requirements [89.73]. Buyer auctions are more prevalent in the B2B market, whereas the seller auction dominates the C2C e-Commerce market. There are different auction formats. In the most common type of auction (called an English auction), buyers bid among themselves, and the winning bid goes to the highest bidder. A variation to this is the Dutch auction, where the seller starts off with an asking price, which is lowered until some participant is willing to accept the price [89.74]. This is commonly used for selling multiple items. Variations to straightforward auctioning could include a *Buy it Now* option, wherein the seller specifies a price at which a buyer could purchase the item and truncate the auction. Apart from facilitating auctions, such sites also allow customers to sell their items at a fixed price as well as to advertise them. There might also be provisions for spe-

cialized individual sellers to exhibit and accept bids for their range of products at their own storefronts [89.75].

What are the factors that influence sellers and buyers to take part in online auctions? The low cost of entry and negligible transaction costs compared with other retail channels make online auctions very attractive. More importantly, there is immediate access to a sizable customer base [89.76, 77]. On the part of the buyer, factors such as ease of use and convenience of using online auctions, as well as potential savings, attract users to online auctions. Apart from these, one other interesting finding was that customers indulge in online auctions for hedonic benefits, such as the fun, entertainment, and emotional value derived from bidding processes [89.78]. The popularity, reputation, responsiveness, and integrity of online auction sites are important to buyers while choosing between online auction platforms [89.31].

89.4 Emerging Trends in e-Commerce

Against this background of B2C, B2B, and C2C e-Commerce markets, we now consider some emerging e-Commerce applications: mobile commerce, telemedicine, and fee-based information delivery.

89.4.1 Mobile Commerce

One of the rising trends in the e-Commerce realm is that of mobile commerce (m-Commerce) wherein e-Commerce activities that were hitherto conducted using fixed-wire Internet are being facilitated by wireless Internet access using devices such as mobile phones, laptop computers, and other portable electronic devices. The driving forces behind m-Commerce include the explosive growth of the mobile phone population and the development of more powerful, sophisticated, and secure wireless technologies. The number of global cellular subscribers is projected to reach 4 billion in 2008 [89.79] and there are 262.7 million wireless users in the US, accounting for a penetration rate of 84% [89.80]. Although mobile shopping remains the major m-Commerce activity, other spheres include banking, information delivery, marketing, and airline ticketing. In particular, mobile banking is witnessing tremendous growth and the number of mobile banking customers in the US is expected to exceed 40 million by 2012 [89.81].

Organizations tend to use m-Commerce in conjunction with their traditional fixed-wire Internet-based outlets so as to provide increased flexibility and convenience for customers, and to cater to a younger and more technology-savvy customer base [89.82]. Major airlines such as American, Delta, and United provide reservation services through mobile devices apart from flight and weather-related information [89.83]. The success of m-Commerce depends on a variety of factors: an organization's ability to integrate existing systems into a mobile environment, development and use of devices that are easy to use and similar to already existing devices, value addition over and above that provided by traditional e-Commerce, and providing customers with relevant, inexpensive, and context- and location-sensitive service [89.83].

89.4.2 Telemedicine: e-Health

The American Telemedicine Association defines telemedicine as *the use of medical information exchanged from one site to another via electronic communications*. Currently, about 2000 medical institutions around the USA are connected through the Internet and other high-speed transmission lines. Of the approximately 200 telemedicine networks in the USA, more than half provide regular clinical services to patients, the others being used for research and education. Apart from the Internet, there are private networks linking hospitals, video systems for real-time patient consultation, and WWW-based patient service. Over 50 different medical specialties, including major ones such as cardiology, dermatology, ophthalmology, and pathology actively use telemedicine in the diagnosis and treatment of diseases [89.84].

Telemedicine facilitates the digital transmission of patient images (or teleradiology), wherein x-rays, computed tomography scans, magnetic resonance images, and digital images of pathology specimens can be sent worldwide for diagnosis and consultation [89.84, 85]. Videoconferencing equipment at physician and patient sites facilitates real-time consultation, especially between urban and rural locations. Using appropriate peripheral devices, it is possible for the physician to examine internal organs and reach an accurate diagnosis and treatment plan, resulting in time and monetary savings. Recent advances in this field include telesurgery, where a surgeon in one location can control a robot in another location via communication networks [89.85].

89.4.3 Fee-Based Information Delivery

Fee-based information delivery services provide information to consumers for a payment. The information may be broad as in the case of New York Times providing news analysis through New York Times Select, or may be narrowly focused as in the case of Wall Street Journal providing financial news, or eHarmony providing potential partner information. Such services used to be free, with their major revenue source being advertising; however as this model became unsustainable, information service providers have shifted to a fee-based model. Most information delivery sites have free content and fee-based premium content.

What is it that motivates customers to pay for material that could perhaps be obtained through other channels? Research indicates that it is the perceived benefits in terms of money, time, decision-making, and learning that attract users to fee-based information delivery. Also, customers tend to choose services that they perceive to be of high quality, are convenient, and provides added value over information delivery through alternative channels [89.32, 34].

89.5 Challenges and Emerging Issues in e-Commerce

The electronic commerce movement is still in its early stages. The big outlines are apparent, but there are many opportunities and challenges. Its future development depends on treatment of numerous issues. Examples of these include trust and legal issues.

89.5.1 Trust and e-Commerce

An important factor that influences B2C e-Commerce adoption is the user's perception of whether the online merchant or website can be trusted [89.45]. Recent surveys have indicated that less than one-half of Internet users actually trust e-Commerce websites, with primary concerns involving the integrity and trustworthiness of online merchants, and the related issue of the safety and security of online transactions [89.86, 87]. The resulting *trust gap* is one of the primary reasons that could impede the growth of B2C e-Commerce [89.46].

What is meant by trust in B2C e-Commerce? Trust has been conceptualized primarily across two dimensions: *faith in humanity* and *vulnerability* [89.45]. The *faith in humanity* conceptualization encompasses the implicit faith that human beings have in the integrity, benevolence, and goodwill existing in the world around them, and the belief that it extends to the e-Commerce world. Thus, a user believes that he/she can rely on a promise made by the online merchant and, in case of problems, it would act toward the user with honesty and benevolence [89.30, 88, 89]. The *vulnerability* conceptualization pertains to the readiness of users to be vulnerable to the actions of the online merchant, wherein the user is fully aware that he/she might have only limited or no influence over the actions of the online merchant [89.45, 90, 91].

In order to enhance user trust in a website, multiple techniques have been examined by researchers. Some of these are incorporated into website design, including website design factors such as the use of third-party assurance seals and certificates, hypertext links from reputed websites and associations, and the usability, usefulness, ease of use, and security control of the interface [89.89, 90]. Using reliable and secure technology and foregoing misleading language, images, and complex terminology serve to enhance user trust in a website [89.91, 92]. Another approach is educating the user by publicizing privacy policies, listing data security precautions incorporated into the website, and laying out procedures regarding compensation, dispute resolution, and mediation [89.30, 93]. Also, displaying positive user feedback from online user communities and providing fair and balanced information regarding similar offerings from competing merchants can serve to enhance user trust [89.94]. The perceived size and reputation of the online merchant and user familiarity and propensity to trust can also influence user adoption [89.88]. Other researchers have pointed out the need for governmental laws and regulation and obtaining informed consent before using private user information [89.92, 95].

89.5.2 Legal Issues in e-Commerce

The e-Commerce market is global and constantly evolving with new and innovative business models and products. As such, it is difficult to structure and enforce a uniform legal framework for conducting online business transactions. Thus, care must be taken by both businesses and consumers to ensure that either side is knowledgeable about the purchase, payment processing, and delivery mechanisms – as well as issues relating to privacy and confidentiality. The best practice would be to adapt the conventions followed in traditional brick-and-mortar sales to the online environment [89.96].

It is recommended that the online business prominently display the sale terms using simple and clear language. When a consumer purchases a product online, it is implicitly assumed that he or she has agreed to the contract; however, it is a good practice to have the customer explicitly accept or reject the contract terms. The terms of the contract should be consistent with product warranty and liability information. In addition, purchase eligibility criteria related to consumer age, geographic region, and product type must be displayed on the website and enforced. These aspects might relate to local and state laws, in which case the website content might have be localized [89.96].

Policies relating to privacy and the use of personal data, fraud, misrepresentation, and nonpayment should be prominently displayed on the website. Encryption tools must ensure the security of transactions and comply with governmental regulations. Care must be taken to ensure that there are no intellectual property violations for products that are displayed for sale. Although not legally mandated for nonfederal websites, it is a good practice to ensure that the website meets or exceeds accessibility criteria [89.97].

89.5.3 Outlook

We have discussed the evolution e-Commerce, reviewed its definitions, frameworks, and success parameters, and examined in detail the three popular areas of e-Commerce. Given its growing importance to consumers and businesses, as well as national and world economies, it is gratifying to note that there is a growing body of academic research addressing unresolved issues of e-Commerce. However, it must be pointed out that the overwhelming majority of research is being conducted in B2C e-Commerce, particularly in the online retail shopping segment. Considering the fact that the B2B e-Commerce market far exceeds the B2C market both in size and turnover, we suggest that researchers take a closer look at issues relevant to B2B transactions. To ensure that e-Commerce research remains relevant to practice, it is important that researchers examine the new and innovative trends in e-Commerce, such as e-Health, m-Commerce (e.g., mobile banking), and c-Commerce. Further research needs to be done on trust- and privacy-related issues as well as on establishing a solid legal framework for conducting e-Commerce transactions. Beyond transactions, there is also need for advances in the development and application of e-Commerce systems that support decision-making [89.98].

90. Business Process Automation

Edward F. Watson, Karyn Holmes

Integrated enterprise-wide information systems (EwIS) are a class of customizable packaged business software applications that have replaced arrays of disparate legacy systems in organizations around the world. EwIS have been the catalyst for the reengineering and automation of core business processes that has led to organization-wide transformation across most industries in corporate America. Chief among this category of packaged business software is enterprise resource planning (ERP), the back-office suite that was embraced by many industries in the 1990s as a cure for legacy system ailments and impending year-2000 (Y2K) disasters. ERP is considered a product of the evolution of an earlier manufacturing planning system referred to as manufacturing resource planning (MRPII). Whereas MRPII was focused on the factory planning environment, ERP incorporates enterprise-wide functionality and therefore is used in virtually all industries. ERP has enabled organizations to streamline, automate, and commoditize their business processes, leveraging best-of-industry practices, quite significantly over the last 15 years. Two other packages that are attributing to this phenomenon are customer relationship management (CRM) and supply chain management (SCM). In this chapter we review EwIS in a historical context as it has developed over the years and discuss the most important characteristics of EwIS today as well as how we expect this field to evolve.

Enterprise-wide information systems (EwIS) are powerful software packages that enable businesses to integrate a variety of disparate functions [90.1]. As pointed out by *Davenport* [90.2], EwIS terminology evolved from the more widely used term enterprise resource planning (ERP). ERP systems, as originally defined, represent the *back-office* of the corporation. EwIS tend to refer to a more generic structure that represents any enterprise application that integrates multiple business functions. The ERP market experienced explosive growth in the USA during the 1990s, due in large part to a little known German software company named SAP – headquartered in Waldorf – that delivered to the US market ERP software of the same name.

In the early 1990s, SAP took the USA by storm, delivering the first comprehensive, real-time ERP system on a client–server platform. Having a well-engineered product and selling the product to C-level executives as a business transformation-enabled solution while Y2K issues were imminent were the necessary ingredients to catapult SAP into the market-leading position. Other vendors, through acquisition and organic growth, scrambled for market share. PeopleSoft, the leading human resource management system, and Oracle, well known for their leading database management system and less known for their business accounting software, both slowly evolved to offer more comprehensive solutions. By the turn of the century, hundreds of ERP vendors surfaced to serve all types and sizes of private and public organizations.

This chapter is broken down into four main parts. The second section, immediately following this first section, describes the business environment when ERP came to the US market in the early 1990s. It then defines the key characteristics of ERP that have essentially defined the new class of standard software applications referred to as enterprise-wide information systems. ERP implications are then discussed since ERP is not simply a software package. Finally, EwIS systems do not stand still, and it is important to understand how they will continue to evolve. The third main section presents the enterprise systems application framework and briefly describes two of the other most significant EwIS applications on the market today: customer relationship management (CRM) and supply chain management (SCM). The fourth main section provides a brief overview of the emerging services industry from the enterprise systems perspective. Finally, the fourth main section looks briefly at future trends of which practitioners and researchers should be aware. This chapter ends with a brief conclusion and a reference list of the significant readings that were used to write this chapter. Related information can also be found in Chap. 54 on *Production, Supply, Logistics, and Distribution*; Chap. 86 on *Enterprise Integration and Interoperability*; and Chap. 88 on *Collaborative e-Work, e-Business, and e-Service*.

90.1 Definitions and Background

Much has been written about the emerging information economy and the challenges corporations around the world face in their quest to shed their legacy systems and processes and transform themselves into lean, agile, and responsive organizations [90.3]. Since the 1970s and 1980s, global competition has threatened the existence of many, if not most, companies in the USA, and management and business consulting organizations have prospered during these times. The search for excellent business practices that would pave the path to success, a concept popularized by *Peters* and *Waterman* in [90.4], led many executives to look for a silver-bullet cure. A paradigm shift, driven by information technology (IT)-enabled radical change, took place in the way companies competed and were managed. Traditional push – or *make-and-sell* – strategies, tied to the annual budget cycle were replaced by radically faster, real-time, *sense-and-respond*, pull strategies [90.5]. Firms learned that they could no longer lead the competition by forecasting customers' needs and then planning the year's production using inventories to match supply and demand. Instead, they had to rely on real-time information to evaluate the needs of each customer continuously. In fact, it was often necessary to anticipate unspecified needs, and then quickly fulfill these needs with customized products and services delivered with unprecedented speed. This shift from an industrial economy to an information economy was accompanied by a simultaneous shift in power from the producer to the (information-empowered) consumer.

During this time, significant emphasis was placed on organizational improvement initiatives such as total quality management, continuous improvement, benchmarking, and employee involvement [90.6]. A competing change paradigm suggested that continuous improvement was not sufficient to make significant advances towards performance excellence and that deeper, systemic change was required [90.7]. Business process reengineering (BPR), a term coined in the 1980s [90.8], provided the means by which an organization could fundamentally change its core business processes and transform itself into a lean, globally competitive, structure. In order to do this, companies were forced to place intense focus on their customer, and to define their core processes based on those, and only those, activities that collectively added value to their internal and external customers. Business processes were streamlined and built around core competencies and capabilities. As we discuss in this paper, an important catalyst for the reengineering and streamlining of back-office business processes was ERP.

The emphasis on the core *business processes* [90.9, 10] of the firm was not easy for most organizations. Redefining the work of an organization based on the customer, instead of on the organization, was a new way of thinking. However, this exercise was necessary in order to clean up years of building systems on top of systems on top of (legacy) systems. An intense focus on the customer became the essential ingredient to success [90.11–13].

With this quest towards efficient and effective business processes under way, organizations quickly realized the challenge of institutionalizing these important process changes. Organizations quickly adopted a multidimensional perspective on these transformation initiatives: people, process, and technology. The foremost significant hurdle to change was the organization's ability and readiness to implement change, the people (also known as, organization) dimension. Implementation-related challenges are discussed later in the chapter. The process dimension presented difficult challenges as companies had to look inside and identify their core processes. Prior to this time, most organizations did not think in terms of *business process*, but instead focused on their performance as defined within their *functional fiefdoms*. Quite some time transpired before corporations fully appreciated the concept of *process*, defined as a set of organized activities that collectively add value to a (internal or external) customer. In fact, companies learned that most business processes crossed functional boundaries, were not easily adopted by the hierarchical organization, and clashed with function-oriented incentive systems.

Figure 90.1 illustrates three core business processes that are well-known and understood today: order-to-cash cycle, fulfill-demand cycle, and procurement cycle. Throughout the 1980s, many companies sought this holy grail of business process definitions independently. There was little success at industry-wide collaboration to achieve best business practices. As every company designed new business processes, they were ultimately challenged to determine how to best implement their new processes. The answer most often was less than optimal as they tied together best-of-breed business applications, spanning multiple computing platforms, or built new applications specific to their needs. The ERP systems introduced to corporate America in the 1990s, as discussed in this chapter, brought to market best practice repositories, built on years and years of experience. And the best way to institutionalize these new processes was through the third dimension of change: technology.

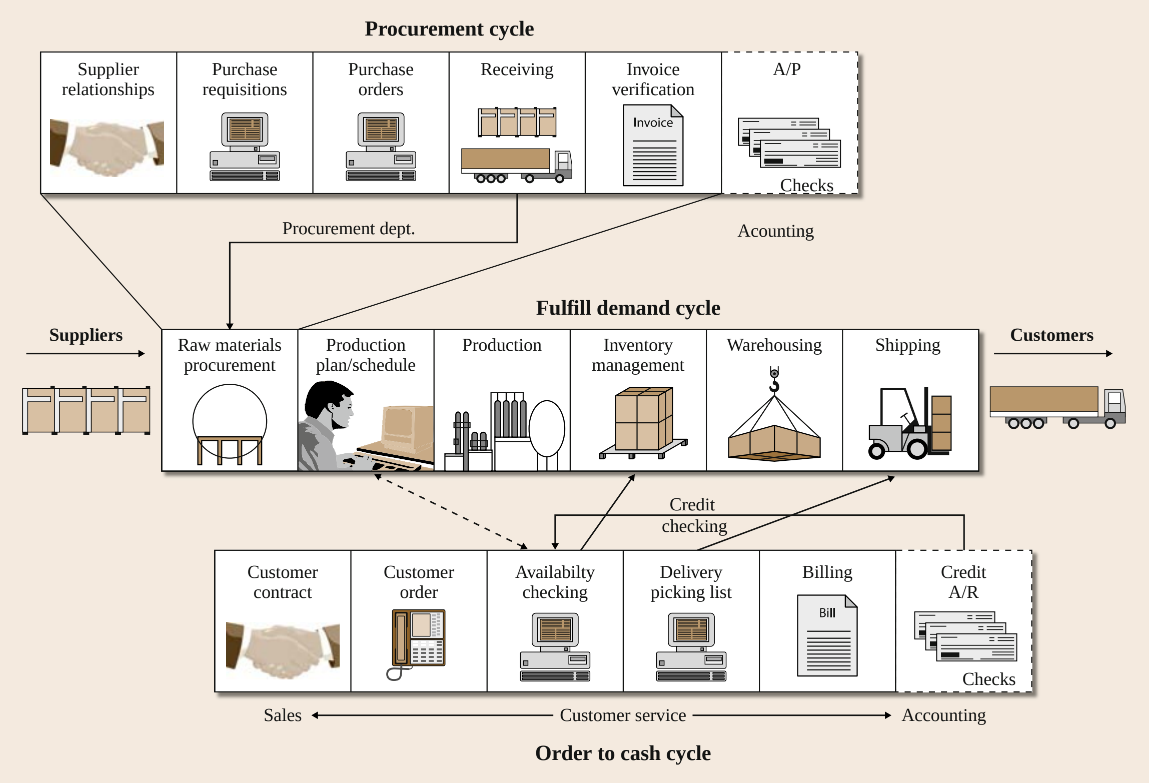

Fig. 90.1 High-level integrated business processes

As we look back to the pre-1990s, we see that advances in technology and corporate computing were also being made. A significant development that triggered the growth in the EwIS market was client–server technology [90.14]. Client–server systems were not based on a single technological innovation, but rather very different development currents in various areas of data processing were united. In particular, progress in the areas of hardware technology, networks, system software, user interface, multimedia applications, object orientation, and software development tools have contributed to this breakthrough. While companies sought to transform their organizations and shed themselves of years of inefficient processes and procedures, they were equally anxious to migrate away from their expensive mainframe computing platforms in order to find a lower-cost, flexible computing environment.

While these advances in the business and technology worlds evolved, another very important concept was also picking up momentum: the use of standard application software [90.15]. Advocates of standard software believed that business processes must be determined independent of the standard software products in order to ensure that business applications are based on business criteria and not on technology platform availability. In this manner, an IT-enabled business transformation effort could be driven by corporate strategy instead of by technological constraints [90.16].

From the EwIS arena, we look first at the flagship ERP system that has been the catalyst for so many business transformation initiatives. We look at what it is and how it enabled business process automation, from the packaged software perspective. We then look at two systems (i. e., CRM and SCM), similar in concept but focused more on a company's outwards-facing processes.

90.1.1 Anatomy of an ERP System

An ERP system represents a grand concept and has been perhaps most effectively defined by SAP AG in an early (1996) company presentation illustrated in Fig. 90.2. In this illustration, the honeycomb structure emphasizes the modular layout of the functional applications as well as the anticipation of always adding or enhancing functionality over time. At the heart of ERP is a common, relational database making all company data available in real time to any authorized user and linking activities across these applications via workflow. An ERP system can be characterized by a number of attributes that are generally common across all EwIS: comprehensive functional modules; business-process-oriented, common, and relational databases; open standards; best business practices; packaged software; business information systems standards; and configurable, common-development-platform, complex workflow capabilities. These attributes are defined for ERP below.

Comprehensive Functional Modules

ERP systems consist of the core (back-office) business applications of four basic functional areas: financials, operations and logistics, sales and marketing, and human resources.

Business Process Oriented

An important idea behind ERP is that the system must support company-wide business process activities, as defined by the company. These activities typically span many functional areas; for example, a typical customer order management process would consist of presales activity, sales order processing, inventory sourcing, delivery, invoicing, and payment [90.17, 18].

Common and Relational

The problem that ERP systems are designed to solve is the fragmentation of information in large business organizations. A common database facilitates the integration of this information into a single information silo. A relational database organizes records into a series of tables linked by common fields [90.19].

Open Standards

The business applications are independent of the operating system and the hardware platform. Thus, a business has the freedom to choose the business application, independent of the operating system and the hardware platform.

Best Business Practices

Best business practices describe a documented collection (i. e., repository) of business processes that have been accumulated over time from the experiences of many businesses within an industry and across many industries. Best practices are typically technology enabled, but they may describe work activity that is independent of technology as well [90.18].

Packaged Software

ERP describes a class of software that is packaged, yet customizable, and is available from ERP vendors. This is one-stop shopping for the user, as a single vendor may offer the complete back-office packaged business suite. This is not to say that a company cannot develop their own system that has ERP characteristics.

Business Information Systems Standards

Packaged software forces business information systems standardization. Examples of where standards exist include data types, organizational types, user interfaces, software development, application interfaces, and reporting.

Configurable

ERP software requires the expertise of business process experts in order to configure the system to support company-specific processes and data. ERP vendors have gone to great extremes to provide template solutions for smaller companies with, relatively speaking, standardized processes.

Common Development Platform

ERP systems are expandable by various means, besides configuration. First, it is typically possible, though not recommended, to *modify* the source code. It is also possible to *extend* the software functionality with third-party application modules and then to link the modules to the ERP system. Finally, ERP users may *link* the software to third-party software packages in order to incorporate more sophisticated or specialized functionality.

Complex

The downside of ERP systems is that, by their very nature, they are somewhat complex. One consequence is that it is very difficult, especially during the software evaluation period, to determine the extent to which an ERP system can represent your business process without actually implementing the process in the software.

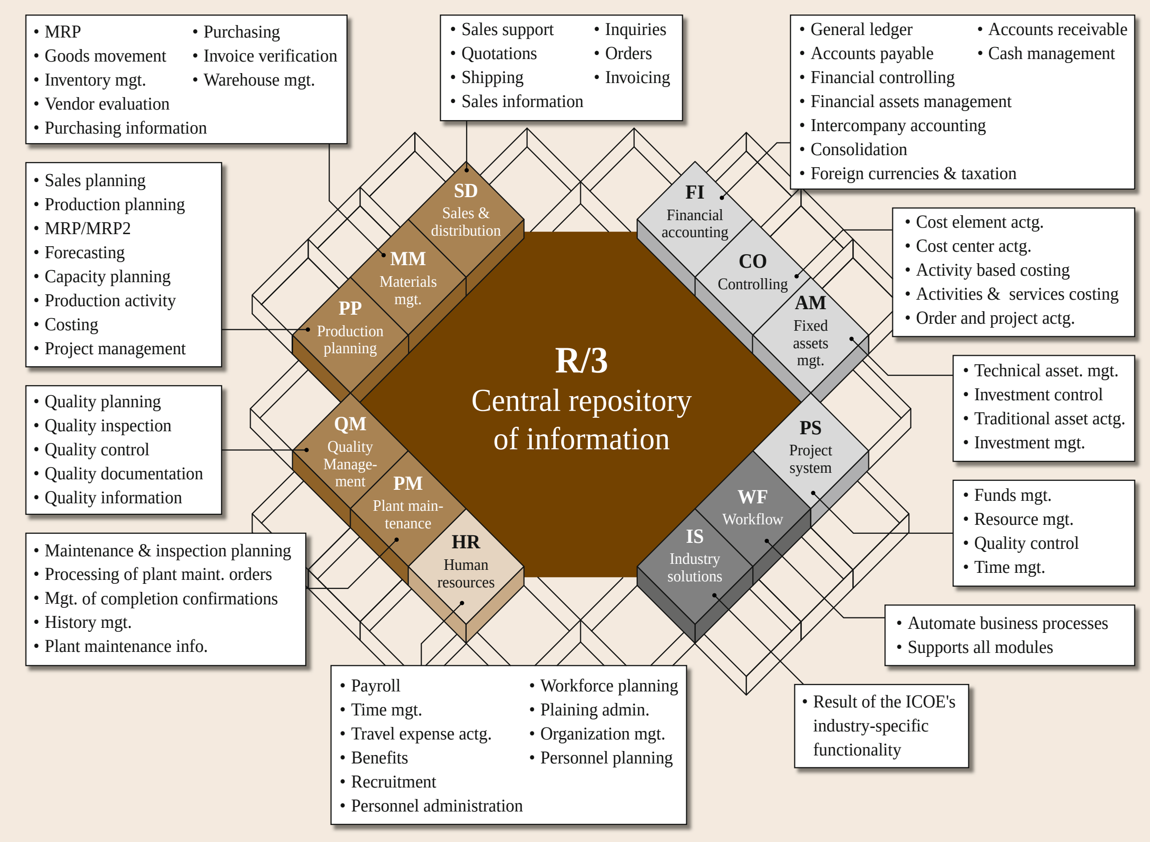

Fig. 90.2 Enterprise resource planning per SAP (after company presentation 1996) (ICOE – Industry Center of Expertise)

Also, similar to the leading office productivity software, Microsoft Office, there is a lot of overhead such that most users use less than 5% of the available functionality.

Workflow Capabilities

This refers to the automation of business processes within the enterprise system. Workflow capabilities permit users to define event-driven routings, create automated in-boxes and prioritized cues, allow background queries to take place with notification to the user, and more generally, to streamline processes.

ERP vendors have accumulated perhaps the greatest collection of industry (best) business practices in digital repositories. In fact, these repositories have become a formidable competitive advantage for the major vendors, specifically, SAP. ERP systems have evolved quickly and as this market is saturated one can see the offerings of each major vendor start to converge such that they (i. e., SAP and Oracle) have more in common in terms of functionality and features than they have that's different.

90.1.2 ERP Implications

The impact of ERP on business in the 1990s was profound. ERP was recognized as the most important development in the corporate use of information technology in the 1990s, even though the Internet received most of the media attention [90.2]. Many believed that "most white collar jobs – as we know them – will disappear as we get the ERP/enterprise resource planning – etc. – 'stuff' right" [90.20, p. 3]. One popular management guru, Michael Hammer, lectured around the globe on the importance of treating an ERP implementation as a major business transformation in demand of strong C-level leadership, instead of as an IT initiative delegated to the IT department [90.21]. Hammer's research identified factors critical to the success of ERP implementation in an organization:

- View ERP as a business transformation initiative (i. e., not a technology initiative)
- Lead the ERP initiative from the C-level (i. e., passionate, focused leadership)
- Give the ERP initiative a high priority relative to all corporate initiatives
- Ensure that the ERP initiative has solid project management and change leadership.

One of the major challenges presented by an ERP system is the need to standardize on technology and on business practices [90.2, 22]. In the purest sense, ERP enables complete standardization of (best) business processes and technologies, as illustrated in Fig. 90.1. However, many companies could not initially reach this hurdle, as reported by Fortune magazine in 1998 [90.23]. Besides implementing ERP to handle order management, production planning, materials management and finance, VF Corp custom developed or used separate software suppliers to augment ERP such as warehouse control (custom), product development (Gerber), micromarketing (Marketmax, Spectra, JDA software, and custom), forecasting (Logility), and capacity planning (i2). As companies decide to add additional software to manage their special circumstances, they inherently choose to take on more costs associated with interconnectivity, data integrity, and maintenance, for example.

Perhaps the most interesting observations the authors have made from talking to many consultants and practitioners over the past decade is that a company must first acknowledge that their limited IT resources should not be spread across the costs associated with developing and customizing the entire enterprise application suite. Instead, it is prudent to look at (roughly) 80% of a company's core business processes as being amenable to standardized business processes using packaged software (e.g., ERP) and industry best practices. The remaining 20% of processes provide the company with a more manageably sized opportunity to create or strengthen a competitive advantage by perhaps customizing a software solution around it. Industry best practices, available as business process templates by ERP vendors, have been provided by software vendors but are actually built upon the cumulative learning of these vendors who have worked with their industry clients. Ultimately, ERP implementation enables a company to build seamless business processes, integrated within the enterprise and across enterprises.

Since ERP first gained popularity in the USA, advocates lauded the integration features whereas others argued for the best-of-breed approach of knitting together the best application packages from the best vendors. This latter group criticized ERP, claiming that one single vendor could not deliver the *best* of everything. Advocates of ERP would argue that integration of good applications is preferred, and that standardization of the 80% of processes (while developing customized approaches for the other 20%) will strengthen the value proposition of the initiative. This concern over integration and best-of-breed has sparked the debate over the emerging service-oriented architecture approach discussed later where vendors promise to deliver comprehensive best-of-breed functionality (services) in a completely integrated and open manner.

ERP initiatives are typically rationalized as the most prudent approach to automate and streamline the back-office business processes by leveraging best business practices and packaged EwIS software. Whereas the earliest companies saw ERP as a way to quickly move from a dysfunctional legacy system, or to avoid Y2K disaster, more recent implementations have been able to learn from the experiences of others and take a more carefully calculated approach to achieve specific business benefits. A study led by *Davenport* and sponsored by Accenture [90.24] found specific benefits resulting from ERP initiatives across diverse industries such as: improved decision making, improved financial management, improved customer service and retention, ease of expansion/growth and increased flexibility, faster, more accurate transactions, head-count reduction, cycle time reduction, improved inventory/asset management, fewer physical resources/better logistics, and increased revenue. *Shang* and *Seddon* developed a more comprehensive framework for assessing and managing the benefits associated with enterprise systems (ES) [90.25]. This research identified five dimensions of ES benefits:

- Operational benefits
- Managerial benefits
- Strategic benefits
- IT infrastructure benefits
- Organizational benefits.

Studies such as these have helped many executives rationalize the ERP initiatives for their organizations. In fact, the same rationalization has been adopted by not-for-profit organizations in government and education industries.

ERP implementation involves the automation of business transactions and this typically requires significant change to how work is done and how decisions are made. It has been shown that the key challenges when implementing ERP and forcing business process change lie in the organization, not the technology. The results from a study conducted by Deloitte Consulting in 2003 reflect this idea. The study also concluded that

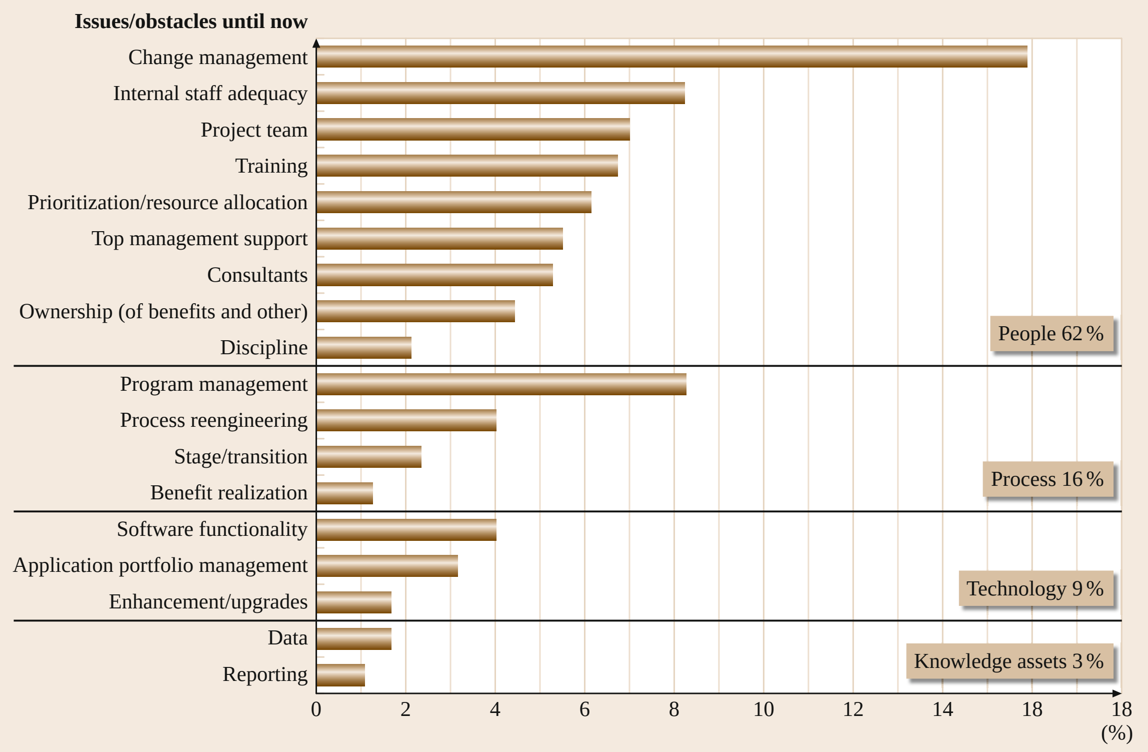

Fig. 90.3 ERP issues prior to going live

people-related issues continue to dominate after the implementation is completed as well.

Similar to best business practices, ERP software vendors today have very well-established implementation methodologies, tools, and templates available for ensuring successful implementations. The implementation process itself is very well understood and standardized, and leverages best implementation practices based on years of implementation experience in hundreds of companies across virtually all industries. Implementation methodologies have key project phases associated with them. SAP's implementation methodology, for example, has five phases: project preparation, business blueprint, realization, final preparation, and go-live and support. Each phase has very detailed work packages and clear deliverables. These methodologies alleviated many project-management-related challenges. Expectations are clear and easier to manage. Communications is specific and timely. Work activity is easier to manage and control as project managers utilize computer-aided tools to better coordinate and control the vast resources and activities associated with the project. Finally, the costs associated with an ERP implementation depend greatly on how much is invested in organizational change and subsequent business process reengineering, change management, and training. However, for perhaps a typical implementation one can view the breakdown of costs to roughly be as follows: 15% software costs, 30% hardware costs, 40% consulting fees (i. e., business process reengineering, software configuration, change management), 15% personnel (i. e., nonproductive time spent working on the project, or in training, or learning curve related), and unfortunately, the remainder which is typically something less than 2%, would go towards training (i. e., end-user training as well as training to develop a core expertise around software development, systems administration, and software configuration).

90.1.3 ERP Evolution

The ERP concept evolved from manufacturing resource planning (MRPII), but the concept was so compelling that it quickly expanded beyond its manufacturing roots into industries such as financial services, government, education, utilities, and retail [90.2]. Until January 1, 2000, there was so much hype around Y2K compliance that not too many organizations looked at ERP issues beyond Y2K. One 1998 study sponsored by Deloitte Consulting [90.26] suggested that there would be a second wave of activity surrounding ERP. The study confirmed that *going live* with ERP is not the end. Rather, going live was viewed as the beginning of a journey toward continuous improvement, innovation, and agility. The *first Wave* referred to the business process changes associated with implementing ERP. The *second wave*, on the other hand, referred to the actions that are taken after going live that help organizations achieve the full potential of ERP-enabled processes (i. e., process optimization). A separate study conducted in 2002 and sponsored by Accenture again emphasized the importance of viewing ERP as continuously evolving. The study suggested that organizations seeking to capture the original promise of enterprise solutions must follow a logical path to *integrate, optimize, and informate* as:

- *Integrate* – unify and harmonize enterprise solutions, data, and processes with an organization's unique existing environment, and use the systems to better connect organizational units and processes, as well as customers and suppliers.
- *Optimize* – standardize most processes using best practices embodied in enterprise solutions software, mold and shape processes to fit the unique strategic needs of the business, and ensure that processes flow and fit with the systems themselves.
- *Informate* – organizations informate by transforming enterprise solutions data into context-rich information and knowledge that supports the unique business analysis and decision-making needs of multiple work forces.

Davenport, in an earlier study [90.27], pointed out that, following their ERP implementation, many companies had trouble realizing the promised benefits. Complete *benefit realization* could take one, two, three or more years. But also, Davenport pointed out that, in order to fully realize the benefits of ERP, companies must figure out how to use the data to support business decisions.

Implementation of ERP does not ensure that the ERP system will be used properly or that the ERP system will lead to value. At the turn of the millennium, studies found that, although many organizations justified their implementation of an ERP on the basis of better decision-making and management processes, few had taken full advantage of the information provided by the system [90.27]. ERP systems were clearly a catalyst for operational process improvements through the simple alignment of business processes and streamlining of information throughout the organization. However, the business world was slow to recognize the potential embedded in ERP for changing management processes such as performance reporting and monitoring, stakeholder communications, and managing customer relations, for instance.

ERP systems left management with a transaction repository filled with terabytes of important business information and data, but there were two problems. First, executives needed something to filter the data and weed out all that was not relevant to their problem at hand. Second, they needed a way to organize, analyze, and interpret the data and then to focus the resulting information on specific actions [90.29]. This realization led enterprise software developers to implement a packaged software strategy and attack higher-level thought processes such as decision making and knowledge management. Indeed, much effort has gone into understanding how the human knowledge creating process works [90.30]. That is, ERP by itself does not provide a competitive advantage but instead it has become a competitive imperative. It provides an effective means to bring order to the back office. Post-ERP companies strive to most effectively leverage their analytic prowess not just to enhance operations but often as their lead competitive differentiator. The extensive use of data, statistical and quantitative analysis, explanatory and predictive modeling, and fact-based management are reportedly being used to drive company decisions and actions [90.31].

ERP software vendors, of course, anticipating this trend, leveraged this packaged software hype and their packaged software competencies, and delivered to the market the concept of the e-Business suite, illustrated in Fig. 90.4 [90.28]. The basic concepts used to develop ERP (e.g., packaged software, based on best business practices) were used to develop *decision-oriented and knowledge-management-type* applications such as customer relationship management (CRM), supplier relationship management (SRM), supply chain management (SCM), strategic enterprise management (SEM), business intelligence (BI), and portals. The products initially delivered to the market had relatively limited functionality and robustness, but over time these products have evolved into quite comprehensive and sophisticated tools for the organization.

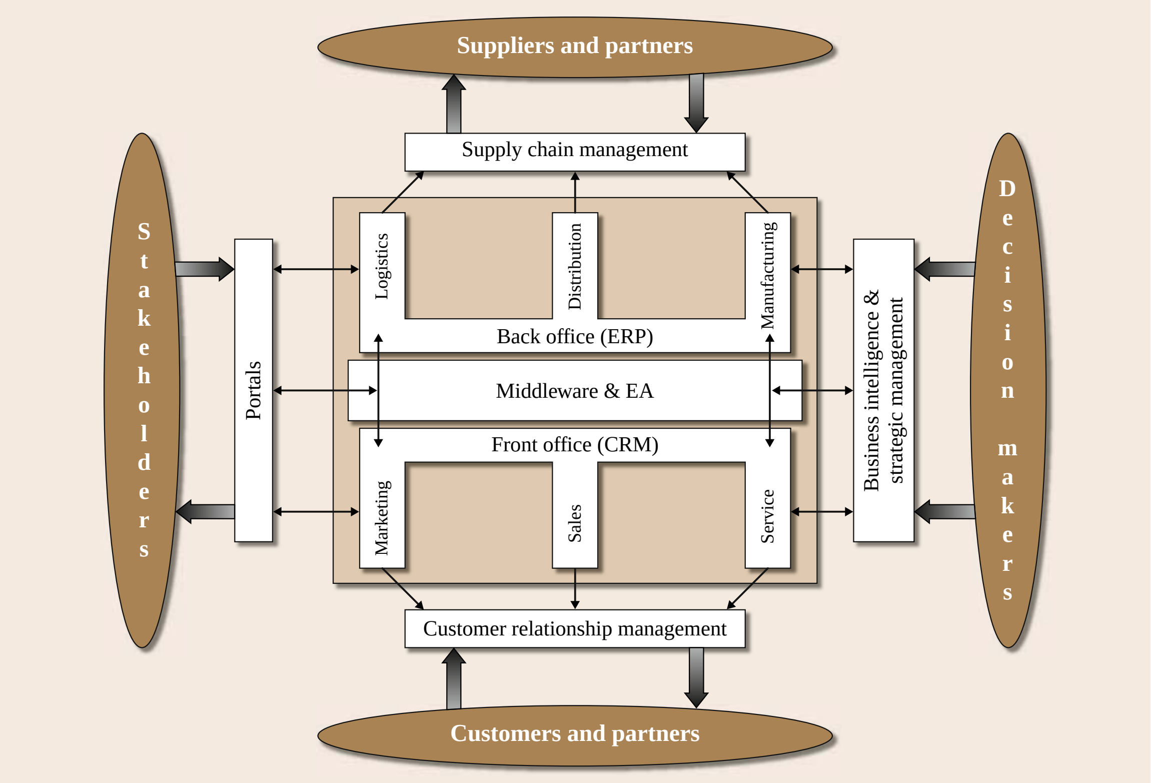

Fig. 90.4 Enterprise application framework (after [90.28])

Ongoing evolution of ERP requires a mechanism to enable, and perhaps promote, continuous improvements as well as disruptive innovations [90.32]. ERP vendors have, to some degree, become the mechanism for improvement and innovation through their version upgrade process. Organizations now struggle to keep current with the latest and greatest developments from ERP vendors. In fact, ERP vendors have developed a sophisticated innovation engine to enable them to lead in the development and delivery of new business models and practices. Being able to leverage the economies of serving multiple businesses within a single industry and across virtually all industries gives vendors this unique perspective and positioning. ERP vendors boast of their very sophisticated innovation processes as they leverage their resources and relationships to deliver to the market product and process innovations frequently. Product and process innovations can originate through various channels as follows:

1. The internal research and development organizations typically include business architects, product developers, software developers, IT professionals, and consultants. These groups assess market and technology trends and determine how best to leverage or evolve the organization's resources.
2. The consulting organization brings years of experience working with their customers to configure the ERP software.
3. The sales organization is closest to the customer on the front end of a sale. They have the best idea of what the customer really wants.
4. Competitor information also provides an important input into the innovation process.
5. Third-party software companies are often acquired to secure recent innovations or in anticipation that the smaller, entrepreneurial firm will help energize the larger, older software vendor.

The Fortune 500 market for ERP has been virtually saturated, so ERP majors are focusing on small- to mid-sized enterprises (SMEs). ERP vendors typically segment their customers based on size (e.g., large accounts greater than US$ 2 billion, local accounts greater than US$ 1 billion, mid-market accounts less than US$ 1 billion and small accounts less then US$ 50 million in annual revenue) and based on channel (i. e., direct and indirect). Different offerings may be available for these different segments.

90.2 Enterprise Systems Application Frameworks

This Section introduces two popular enterprise applications referred to as customer relationship management (CRM) and supply chain management (SCM). Although the actual application may be defined differently by different vendors, relatively generic application frameworks are presented below to facilitate this introduction.

90.2.1 Customer Relationship Management

Customer relationship management (CRM) is a broad term that refers to the way an organization manages all aspects of its interactions with customers. The term is widely used to describe software packages that enable and support the management of customer interactions, including such areas as sales, marketing, and service. Such packages are often integrated with ERP systems or other enterprise-wide applications. The popularity of CRM applications reflects a shift in focus to the customer and the importance placed on creating, maintaining, and enhancing customer relationships.

CRM functionality is often divided into three categories: operational, analytical, and collaborative (Fig. 90.5). The operational aspects of CRM include those that support front-office processes involving the customer. This can include order processing systems, marketing initiatives, customer service departments, and call centers. Analytical CRM refers to the functionality involved with analyzing and predicting customer behavior. This can involve sales forecasting as well as the use of data warehouses, where large amounts of customer data are mined to discover trends and other important interactions. Finally, collaborative CRM functions are those that actively involve the customer to increase their satisfaction and better meet their needs. This category usually refers to various types of interactions with customers that are not driven by customer service representatives, such as interactive websites.

Current CRM software is much more comprehensive than a simple sales system. The application must support the entire customer process, which spans various departments and functional areas: marketing bases campaigns on customer input and generates customer leads; sales uses these leads to generate customers; manufacturing, distribution, and accounting are involved in processing customer orders; customer service handles complaints and questions; and research and product development are influenced by customer preferences [90.28]. A CRM application strives to integrate the flow of information across these various areas in order to improve decision making. For example, when a customer places an order, the CRM system is updated with this information. When the same customer calls with a problem about the order, the CRM system can recognize the customer and route the problem to an appropriate sales representative (operational CRM). The system generates sales suggestions based on past purchases that can be pitched to the customer through e-Mails or websites (collaborative CRM). Customer service calls can also be analyzed to correct common problems and anticipate new issues (analytical CRM) [90.33].

The evolution of the CRM market from simple sales force software to large, integrated applications has led to the prediction of several trends that should begin to influence the growth of this market, according to studies by *Forrester* [90.34, 35]:

- Significant growth will come from mid-market companies and from hosted applications (Sect. 90.2.3).
- CRM vendors will broaden solutions, with order management as one of the top areas.
- Increased focus will be placed on making systems proactive (i. e., predicting customer needs, preferences, and problems before they arise).

While the growth of the CRM application market may only prove modest, there is substantial expected growth in the adoption of CRM practices as part of business strategy.

90.2.2 Supply Chain Management

A supply chain refers to an organization's network of suppliers, manufacturers, wholesalers, distributers, retailers, customers, and partners. Supply chain management (SCM) can be described as the management and coordination of processes – particularly information, material, and financial flows – across a supply chain (Fig. 90.5). Thus, there is both an internal and external focus inherent to SCM. The term also refers to the category of software applications that aim to control and optimize these processes for organizations. While ERP products focus on the coordination and integration of activities within a particular organization, SCM products extend this scope to include interorganizational activities [90.36]. Ideally, these applications will allow communication and integration across the multiple organizations involved in a supply chain to produce responsive, synchronized, and efficient processes. Some of the activities typically included in SCM software include procurement, order fulfillment, demand management, inventory management, warehousing, transportation, manufacturing, and requirements planning. The arrows in Fig. 90.6 represent the mainstream flow for materials, information and money, but it is important to note that, in practice, these arrows are bidirectional as there is significant interaction between each stage when dealing with material, information or money.

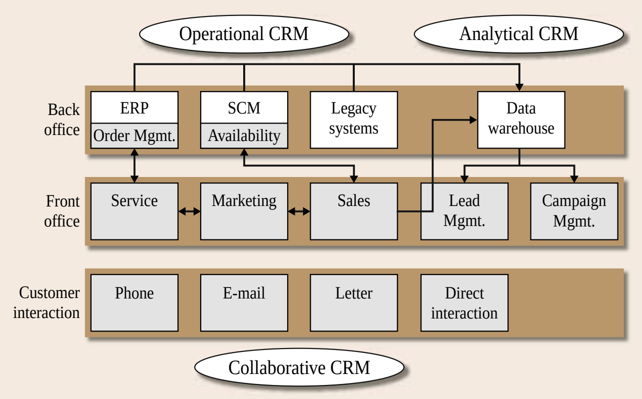

Fig. 90.5 CRM capabilities (after Microsoft Corporation 2000)

SCM functionality can be described as involving planning, execution, coordination, and networking (also referred to as collaboration) [90.37]. Planning includes the design of the supply chain as well as planning supply and demand across the entire chain. This involves forecasting and planning for production, ordering, and distribution. Execution is the automation of the ordering, production, replenishment, and distribution processes and generally focuses on the distribution and manufacturing facilities [90.28, 38]. Coordination involves managing the interaction of processes to increase customer satisfaction. Examples of coordination functions are monitoring and assessing performance. Finally, networking in SCM refers to communication across the supply chain through information sharing.

One of the goals of SCM is to match supply and demand across the supply chain. Demand generated by the end customer travels upstream throughout the

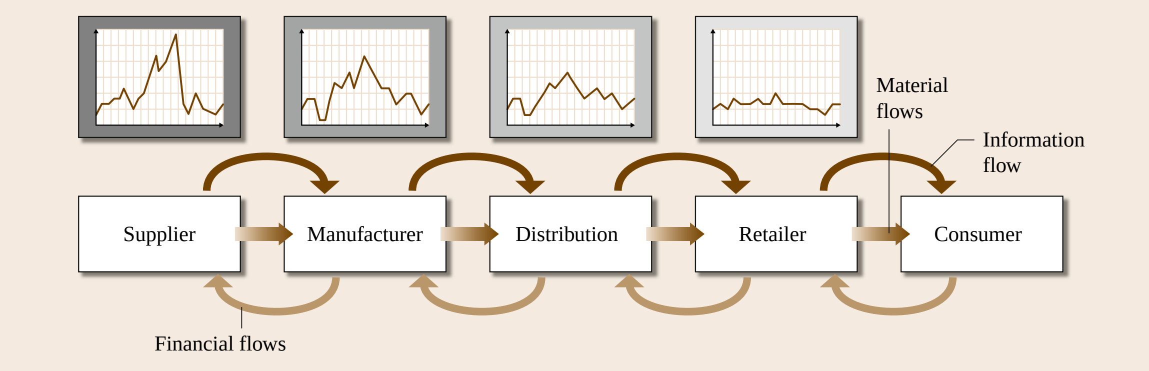

Fig. 90.6 Supply chain flows (after [90.28, 37])

supply chain (i. e., customer demand drives retailer demand, which drives wholesaler demand, etc.). Many supply chains experience what is known as the *bullwhip effect*, where small fluctuations in customer demand are magnified along the supply chain, causing larger demand fluctuations as one moves backward along the chain [90.36]. SCM aims to reduce this effect. By providing interenterprise integration that coordinates processes and shares information, organizations should see reduced demand fluctuations and increased service.

The evolution of the supply chain itself (i. e., in the form of just-in-time and continuous replenishment methods) have changed requirements for supply chains, and therefore SCM solutions [90.28]. The uses of new technologies, such as radiofrequency identification (RFID) tags, are continually integrated into SCM applications to provide greater and greater functionality. The SCM solutions market is expected to experience an increased focus by major vendors to provide supply chain solutions to service organizations and also to experience growth in the customization of solutions by independent software vendors [90.39].

From a software solution perspective, there are three major categories of supply chain solution providers: major ERP vendors, specialty supply chain vendors, and systems integrators. As can be expected, major ERP vendors (such as SAP, Oracle, and to some degree Microsoft for the small- and medium-sized enterprise – SME – market) have acquired or built, and deliver to market, competitive supply chain management software packages. Their competitive advantage includes: size (deep pockets), customer install base (via ERP solutions), best practices (developed over the years, a significant amount of *supply chain* activity involves ERP functionality and transactions), research and development resources, partners ecosystem, and packaged software experience. The specialty supply chain vendors, i2 and JDA, for instance, will typically have deep knowledge in one or more industries and also share some of the advantages of the major ERP vendors (listed above) perhaps to a lesser degree, and varying between vendors. The systems integrators, IBM and BEA, are effective at customizing and piecing together supply chain solutions to address specific customer concerns.

90.2.3 e-Business

It is important to point out that EwIS applications have been designed to operate within a greater e-Business framework. That is, these applications may be delivered across the Internet in formats such as application service provision (ASP). In fact, the leading CRM vendor today offers their solution only in this format. A study conducted by *Forrester* in 2005 [90.40] identified three types of CRM vendors: hosted CRM specialists (i. e., vendors focused on providing on-demand CRM), hosted all-in-one vendors (i. e., vendors dedicated to the on-demand delivery model but who have chosen to expand beyond CRM to provide built-in support for back-office systems such as ERP and order management), and licensed CRM vendors. One can expect these sorts of offerings for other enterprise applications such as SCM and SEM.

90.3 Emerging Standards and Technology

One of the most significant movements that have emerged since 2000 in the enterprise systems market is one towards building business processes from services. Based on service-oriented architecture (SOA) and its associated standards (e.g., web service definition language (WSDL), simple object access protocol (SOAP), and universal description discovery and integration (UDDI)), this represents a step in the evolution towards developing and implementing flexible enterprise software. It is important to point out that SOA is an architectural approach and not a competitor to packaged software. That is, packaged software is a codification of a company's business processes. Packaged software is delivered to the market with varying degrees of configurability, so it will have varying degrees of flexibility since it uses, in its traditional form, proprietary file formats and interfaces. The SOA movement provides a more open platform that allows a company to redefine packaged applications as loosely coupled business services combined with processes. Packaged software applications can adopt SOA for interoperability and extensibility. In fact, the major packaged software vendors such as SAP and Oracle have made bet-the-company decisions based on delivering solutions on an SOA foundation. On the other hand, platform vendors such as Microsoft and IBM have reconfigured their product line around SOA-based solutions. The concept of packaging business processes as services and the competitive landscape that is emerging to support this movement are discussed below.

90.3.1 Services Concept

SOA is based on the concept of stringing together many loosely coupled, message-based *building blocks* of processes, called services, to create a customized application [90.41]. With regard to enterprise systems, this marks a move from having one integrated application that runs all or most of an organization's processes to a method of combining multiple services from many sources to form customized business processes; for example, an organization can combine a service that checks inventory availability with one that processes customer payment into part of a customer order process. SOA promotes code reuse, as services can be reused to form many applications, and flexibility, as services can be combined and recombined in infinite ways to match the changing business logic of an organization. Web services connect via the Internet and are published in a standard format with standard interfaces, so that each service can communicate with other services without regard to the underlying technical details (i. e., which programming language was used) [90.41]. Two of the goals of enterprise systems based on SOA are to reduce customization costs and to allow a focus on modeling and remodeling business processes instead of focusing on technical details.

90.3.2 Competitive Landscape

The SOA approach to automating business processes requires ERP vendors to shift focus from providing integrated solutions to providing a platform for combining and running services. Vendors are now developing a more *open* interoperable platform where SOA applications can be developed and accessed and where the software can be easily integrated or interfaced with services and products of other vendors [90.42]. One of the key components in each of these platforms is the enterprise service bus (ESB) that handles the communication between services. Many of the current offerings of SOA-enabled infrastructures, in various states of their roll-out, have come from well-established names in the enterprise systems and middleware domains: SAP, IBM, Oracle, and Microsoft. Some of these platforms include preconfigured services based on functionality contained in the vendor's previous products, while others simply provide the platform for developing custom services and for deploying third-party vendor services. These offerings are briefly discussed below and are summarized in Table 90.1.

SAP markets enterprise SOA through its NetWeaver platform. Functionality from SAP's other applications are being divided into thousands of prepackaged but changeable sets, described by SAP as bundles. NetWeaver's key component is the enterprise services repository (ESR) that serves as a metadata directory for the available services and provides a UDDI-compliant registry for publishing, classifying, and discovering services. SAP also intends to leverage their industry experience by providing industry-specific business processes for over 25 industries [90.43].

Oracle's SOA Suite is a package of several Oracle Fusion Middleware products designed to provide a comprehensive SOA infrastructure in one installation [90.44]. The suite is intended to serve as a way to integrate the various technologies acquired by Oracle. Functionality configured as services will be delivered

Table 90.1 Comparison of selected SOA bendors ([1]Provided through Fusion Applications; [2]UDDI compliant)

Vendor	SOA initiative	Platform	Example modeling and development tools	Prepackaged services	Service registry
SAP	ESOA	NetWeaver	WebDynpro, NetWeaver Visual composer	Yes	Enterprise services repository[2]
Oracle	SOA suite	Fusion Middleware	JDeveloper, BPEL Process manager	Yes[1]	Oracle service registry[2]
IBM	SOA foundation	Websphere	Websphere business Modeler, Websphere integration developer	No	Websphere service registry and repository
Microsoft	Microsoft application plattform	.Net, BizTalk	.NET framework	No	Enterprise UDDI services[2]

through Fusion Applications (due for full release in 2008) and will run on the Fusion Middleware infrastructure [90.45].

IBM markets IBM SOA Foundation as a set of modular software that can be adopted one component at a time [90.46]. Most of these components, including the Websphere Business Modeler and the Websphere ESB, are identified with the Websphere name. The Websphere Service Registry & Repository is based on emerging standards rather than UDDI but will be able to integrate with UDDI-based registries.

Microsoft's more limited SOA offering, based on the Microsoft application platform, is directed towards the mid-market. The foundation of the Microsoft application platform is the .NET framework, which allows the development of services and connection of systems [90.47]. Most ESB capabilities reside in their BizTalk Server.

90.4 Future Trends

Enterprise systems vendors continue to strengthen their products. One recent study [90.48] points to a number of ERP trends that mark the maturity of this market: companies are standardizing on a single ERP vendor, companies are moving toward fewer software instances, comprehensive ERP offerings reduce the need for best-of-breed bolt-ons, industry-specific functionality is getting deeper, and integration capabilities are improving.

Recognizing the trend that enterprise systems powerful applications are being made available to virtually all types of employees and consumers, instead of just sophisticated users, enterprise systems vendors are very keen to better understand the needs of the emerging enterprise knowledge workers [90.49]. Workers who come from all industries and all levels of the organization are expected to leverage the power of enterprise systems to be more effective in their jobs. Vendors will be challenged to further help develop simplified work processes for companies to implement, simplified IT infrastructures that users do not even know exist, and simplified user interfaces that allow end-users to leverage the power of the systems without knowing that they are using a system.

As the global market place does indeed become flatter and as these sophisticated software systems do indeed become more simplified and commoditized, more emphasis will be placed on service-oriented architectures and business process modeling to create nimble, agile, dynamic structures that evolve as quickly as the business models that employ them.

90.5 Conclusion

The enterprise systems market was rooted in the development of ERP and has since leveraged ERP concepts to effectively deliver sophisticated business applications such as CRM and SCM. Enterprise systems have become the enabler of continuous improvement and disruptive innovation for organizations around the world. ES vendors play a significant role as thought leaders and change agents. In a short period of time, the corporate computing landscape has been radically transformed as companies have endless opportunities to leverage information and networks like never before.

91. Automation in Financial Services

William Richmond

This chapter addresses automation in the financial services industry with a focus on small banks and credit unions. The financial services industry includes all organizations that engage in or facilitate financial transactions. Automation is essential for these firms to both lower cost and differentiate their services. Small banks and credit unions are an important subset of this industry, with unique automation needs to enable them to compete with large, international firms.

The chapter begins with a description of the financial services industry in general, then moves on to describe community banks and credit unions, how they operate, and the role of automation. The chapter then addresses two key automation areas for these institutions: their core systems that support basic account processing, and a key customer-facing system – Internet banking. Factors that drive success and recommendations for how to approach each of these automation areas is discussed. For these small financial institutions, successful automation of back-end systems depends on how they source the system, with outsourcing both raising costs and the number of channels through which they distribute their products. Successful automation of customer-facing systems, such as Internet banking, depends on getting their customers to use the system. Because of this, success is more of a management than a technical issue. The chapter concludes with a discussion of emerging trends, technologies, and issues.

According to the North American Industry Classification System (NAICS) [91.1], there are approximately 500 000 financial services firms. This includes insurance agencies, commercial banks, securities brokerages, securities exchanges, and the Federal Reserve banks. These companies range in size from Citigroup, with almost US$ 1.5 trillion is assets [91.2], to the Wanda Michalenko Memorial credit union with around US$ 30 k in assets [91.3]. All of the firms in the financial services industry are information-based businesses, and the intangible nature of the products and services drives the automation projects required to enable these businesses to exist and thrive. Automation of the capture or transmission of information improves productivity, and delivering new products and services typically requires new or modified systems.

Given the size and breadth of the financial services industry, this chapter focuses on small banks and credit unions. These institutions have unique automation needs. They compete against giant companies, such as Citigroup and Bank of America. They need to offer comparable services at competitive prices, but they do not have the deep pockets to fund automation projects and innovation. At the simplest level, these organizations provide a place for people to store cash and from which to make payments. They also support the lending process. Processing deposits, payments, and loans is complicated, and supporting these processes usually entails automation provided and supported by numerous parties.

For these institutions, two areas of automation are critical, and are addressed in more detail throughout this chapter. First is their automation of their core systems. These systems support the bank or credit unions back-office operations. Second is their customer-facing systems, such as Internet banking. A small bank or credit union's automation is successful if it lowers their cost structure or enables them to differentiate their products or services.

For their core processing (deposit and loan processing), how they source their core processing affects their cost structure, the number of products they offer, the number of channels through which those products are available, and to a lesser degree what they pay for deposits. Thus how small banks and credit unions source their core systems is linked with key strategic decisions, such as their product and service offerings, their distribution channels, and their pricing.

For customer-facing systems, the key to success is user adoption. Improved profits initially result from increased revenues despite increased costs. To obtain these profits requires attaining a certain level of customer adoption. If enough customers adopt, the bank or credit union will start to see decreased costs as well. Unfortunately, for the majority of small banks and credit unions, reaching the Internet banking user adoption level breakpoints constitutes a major undertaking – one that they should be wary of taking without a good understanding of both the economics and their customers.

91.1 Overview of the Financial Service Industry

The financial services industry includes all organizations that engage in creating and trading financial assets; act as financial intermediaries by raising funds from lenders and providing funds to borrowers; pool risk to protect entities from specific losses in exchange for a periodic payment (insurance); and facilitate these financial transactions [91.4]. Firms engaging in creating and trading financial assets include securities brokers, who act as agents between buyers and sellers of securities; stock exchanges, which furnish physical or electronic marketplaces; and portfolio management firms that manage others' assets for a fee or commission. These include institutions with which everyone is familiar, such as Goldman Sachs, the New York Stock Exchange, and T. Rowe Price. It also includes less well-know businesses, such as the Arizona Stock Exchange, Dwight Investment Counsel, and Liebau Asset Management Company.

Firms that act as financial intermediaries include commercial banks, credit unions, and savings and loans. The lines between these institutions are blurring, and all of them accept deposits and make commercial, industrial, and consumer loans. Linked with these institutions are credit-card processors and loan brokers. Credit-card processors provide retailers with a merchant account and enable them to process credit-card transactions. Loan brokers, including mortgage brokers, help customers find the best loans. They act as an intermediary between lending institutions and the customer. Institutions which, perhaps, should be linked with these firms are other loan originators and processors, such as the financing arms of the automobile industry. Financial intermediaries include well-known firms such as Bank of America, and Citigroup as well as the Wanda Michalenko Memorial credit union.

Risk pooling firms include insurance carriers and their agents. Insurance carriers analyze risk and then assign an appropriate premium for assuming that risk. Agents, like securities brokers, act for the carriers and sell the insurance policies to individual and companies. These include firms form Aflac and Geico to the Wayah Insurance Group.

All of the firms in the financial services industry are information-based businesses. Their products and services are (or can be) intangible, and the processes for delivering these products and services entail the capture, aggregation, transmission, and dissemination of information and knowledge. The intangible nature of the products and services drives the creation and delivery of products and services, the structure of the business, and the nature of competition, as well as the automation projects required to enable the businesses to exist and thrive.

Because financial service firms are information based, new products require only creativity to define. A new mutual fund groups a set of existing stocks.

A new insurance product protects a customer from a risk they had not insured before. A new type of loan makes funds available to borrowers with different contract terms than existing loans. Frequently, new products are amalgamations of other, existing products; for example, a new banking product will often be a set of accounts (e.g., a savings account, a checking account, a consumer loan) with certain requirements, such as minimum balances and minimum or maximum activity levels. Identifying and defining a new product that will be successful, however, is extremely difficult. The new product must appeal to a customer base. It must comply with government regulations. It must be priced effectively and it will likely require new or modified systems to support the processes for implementing it.

Because products and services are intangible, they are easy for competitors to copy. Copying the product or service requires knowing its terms or components (e.g., knowing the terms and structure of a new loan product or knowing the accounts and limits for a new type of bank account) and then implementing the processes and systems required to support the product; for example, Prudential offers MyTerm *a new, immediate-issue term life insurance product available through the internet to customers of select banks and other financial institutions* [91.5]. This product is available through banks. To implement it, a bank connects its systems to Prudential's systems, so it will be easy for any bank to offer. For another insurance company to offer a similar product requires similar systems, but they have a model on which to base them. It would also require an understanding of the risk, but they would not have to start their analysis from scratch.

In part due to the ease of product creation and duplication, at least on the retail side, entry into the financial services industry is easy. Starting a bank requires only

US$ 6 million in capital. Starting a credit union requires less. Becoming a financial planner, in most places, does not require formal financial education or expertise, so entering the market is easy and inexpensive. The easy market entry and low startup costs increase competition, since it results in a large number of competitors with both large international players and with small local firms.

According to NAICS [91.1], there are approximately 500 000 financial services firms. This includes over 150 000 insurance agencies and brokerages, 50 000 commercial banks, 25 000 securities brokerages, and the 7 Federal Reserve banks. These companies range in size from Citigroup with almost US$ 1.5 trillion is assets [91.2] to the Wanda Michalenko Memorial credit union with around US$ 30 k in assets [91.3].

Automation plays a central role in financial service firms. Automation of the capture or transmission of information improves productivity. This has led banks and credit unions to automate their core processes, stock exchanges to automate the matching and execution of trades, and stock brokerages to implement algorithmic (program) trading. These automation projects have significantly changed the financial services industry. Banks' automation of their core systems changed the industry cost structure and was a key determinant in industry consolidation [91.6]. Big Bang – the automation of the London Stock Exchange trading – enabled the stock exchange to increase trading volume from 20 000 shares a day to over 550 000 shares a day [91.7], and program trading affects the stock market's value [91.8] as well as accounting for over 50% of the trades on the New York Stock Exchange (NYSE) [91.9]. Table 91.1 lists some of the types of firms that comprise the financial services industry as well as some of the ways in which they are using automation.

91.2 Community Banks and Credit Unions

Because of the size and breadth of the industry, the remainder of this chapter focuses on small community banks and on credit unions. These institutions have unique automation needs. They compete against giant companies, such as Citigroup and Bank of America. They need to offer comparable services at competitive prices, but they do not have the deep pockets to fund automation projects and innovation.

Community banks, for the purposes of this chapter, are relatively small, regionally localized banks. There are thousands of banks with less than US$ 2 billion in assets and that serve only part of a state or regional area. Credit unions are nonprofit, cooperative financial institutions with the motto: *not for profit, not for charity, but for service* [91.10]. Each credit union is chartered to serve a defined membership; for example, the Houston Texas Fire Fighters Federal Credit Union only serves fire fighters and their families in Houston, TX. With such targeted markets, credit unions are small. The largest credit unions had less than US$ 2.5 billion in assets in 2005.

Both retail banks and credit unions make their money on fees charged for their services and on the spread between the interest they pay and the interest they earn. To compete, they must offer both competitive rates and competitive services. Some credit unions and small community banks offer only very limited accounts, loans, and services. Others offer a full range of accounts, loans, and services.

Banks and credit unions differ in their goals and objectives. Banks try to minimize their cost of capital and maximize their risk-adjusted loan rate. Conversely, credit unions try to maximize their cost of capital (the interest rates they pay on deposits for members) and minimize their risk-adjusted loan rate (subject, of course to maximizing the amount and number of loans they make to their members). Ultimately, credit unions are operated for their members, aligning the interests of owners and customers, while banks are operated for their shareholders, resulting in maximizing returns for owners while simply satisficing customer needs.

91.2.1 How a Retail Bank/Credit Union Works

At the simplest level, banks and credit unions provide two services. First, they provide a safe and convenient place for people to store cash and from which to make payments. Second, they match people with excess cash with those who need cash and then support the lending process. Processing these sets of transactions is complicated and frequently entails substantial automation [91.11].

Figure 91.1 shows some of the interactions and some of the detail for processing deposits, payments, and loans. The key points from Fig. 91.1 are that the customer interacts with the bank in numerous different ways through various channels, and that there is

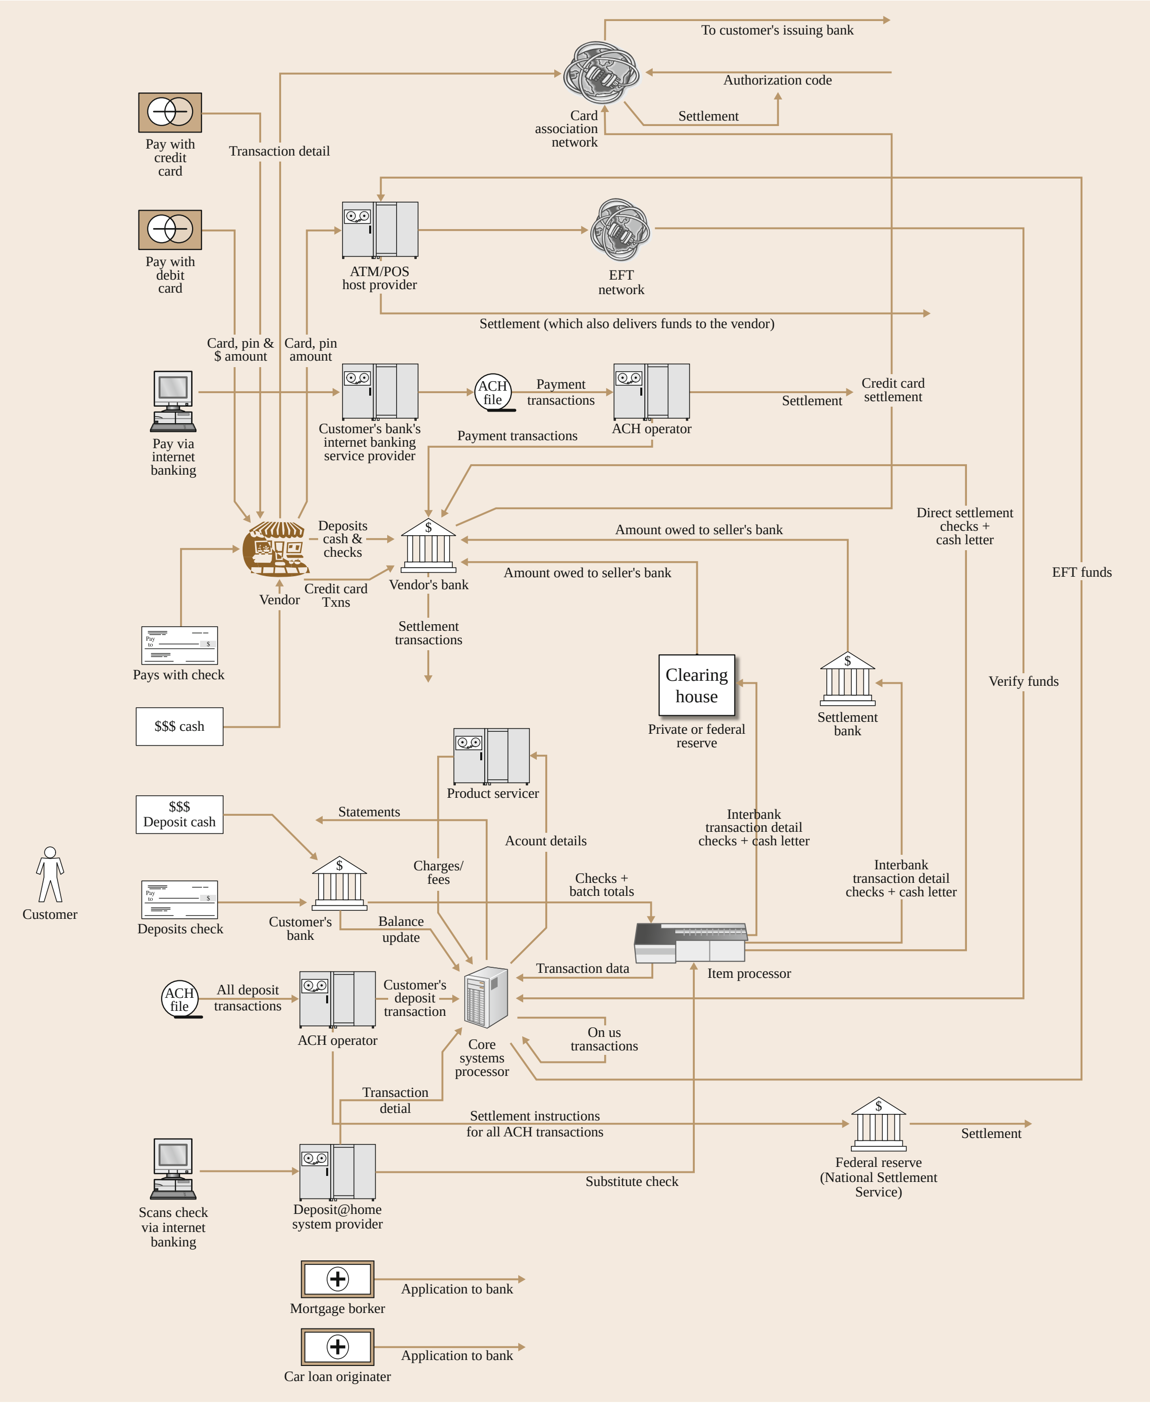

Fig. 91.1 Basic bank and credit union processing

a complex set of systems operated by different parties required to support those interactions.

Customer Deposits

When a customer makes a deposit, the bank records the deposit and updates the amount it owes the customer. To make a deposit, a customer can:

1. Take cash to the bank
2. Deposit a check at the bank
3. Have someone (e.g., an employer) make a deposit via automated clearing house (ACH)
4. Scan a check at their home.

Each of these requires a somewhat different process, different systems, and potentially different companies running the systems. When the customer takes cask to the bank, the teller counts it and enters the amount into their core system, which updates what the bank owes the customer.

When the customer deposits a check, the process is more complicated. The deposited check must be encoded by the teller with the amount of the check. Checks are batched up and sent to item processing. Item processing sorts the checks by paying bank and account. This may be done by the bank or by a third party. The bank's core systems are updated with transaction details and checks are processed for settlement.

Settlement can occur in numerous ways. On-us transactions are checks written on other accounts at the same bank. For these, the bank withdraws money from one of its accounts and deposits it in another (assuming there is enough money available). This is just processing a set of accounting transactions. When the check is written on a different bank, the customer's bank can settle with the other bank directly, through a clearing house, or through a settlement (or correspondent) bank. With direct settlement, the checks are presented to the check writer or payer's bank and that bank uses a service, such as Fedwire, to transfer funds to the customer bank (Fedwire is a real-time funds transfer system operated by the Federal Reserve banks). With a settlement bank or clearing house, the checks and cash letter are sent and the clearing house nets all of the transaction for all of the participating financial institutions. It then uses its own accounts or the Federal Reserve National Settlement System (NSS) to debit or credit the correct amounts to each participating institution. Transaction details are also sent to each institution, so they can debit or credit the appropriate customer accounts.

For deposits made via ACH, the payer (such as an employer) provides *its* bank with instructions for creating a file with all of the deposits it will make. The payer's bank – the originating depository financial institution (ODFI) – creates or verifies the file and sends it to an ACH operator. The ACH operator routes the files to the payee (customer's) bank. It then settles the transactions via the Federal Reserve.

Customers can also deposit checks from their home by scanning both sides of the check and submitting the files. The system supporting this process is either administered by the Internet banking service provider or by yet another service provider. The scanned check becomes a *substitute check* (approved by the Check 21 law) and the electronic information is processed like a check that has made it through the item processing stage. This information must be passed from the Internet banking or deposit at-home service provider to the bank's system.

Note that in all of these cases, cash is not flowing from one bank to another. Only information – changes to account balances – is flowing. Also note that there are numerous kinks in the flow. The check may be damaged, requiring manual processing at the item processor. The check may be fraudulent or there may be insufficient funds in the payer's account which will prevent settlement and require the customer's bank to reverse the deposit. These kinks complicate the information flow and require sophisticated automation and processes.

Payments

When a customer makes a payment, the bank records the payment and updates the customer's account. It also goes through a settlement process to get the appropriate amount to the payee. To make a payment, the customer can:

1. Pay with cash
2. Pay with a check
3. Initiate an ACH credit transaction
4. Initiate an ACH debit transaction
5. Pay with debit card
6. Pay with credit card.

To pay with cash, a customer just hands over cash. The only role the bank plays is providing cash to the customer and receiving the cash from the vendor. When paying with a check, the process is the same as when the customer deposits the check. The only difference is that the vendor is depositing the check. In some places, the vendor scans the check at the time of purchase. This converts the check to an electronic form and an ACH (or electronic funds transfer (EFT)) transaction occurs, similar to a debit-card transaction.

Bank customers can also use ACH to pay bills. Typically, this is through either the Internet banking system or a vendor's system. When the customer uses the Internet banking system's bill-pay feature, they can set up a recurring payment. They tell their bank to withdraw funds and to pay a certain account. Alternatively, they can use a vendor's system and give the vendor authorization to withdraw money from their account. This frequently happens with recurring payments such as mortgages, and insurance premiums. This process is the same as when they deposit funds via ACH, except they are the payer instead of the payee.

To pay with a debit card (which is similar to using an automated teller machine (ATM)), the customer provides their card and pin (there is also a signature version). The debit card/ATM system may be driven by a third party. The transaction is forwarded through the EFT network to verify that the customer's funds are available. If so, the account is debited and an electronic funds transaction transfers funds to the debit card/ATM host provider. The debit card/ATM host provider then uses ACH to transfer funds to the merchant/ATM owner.

To pay with a credit card, the customer provides their credit card. The transaction information is transmitted through the card association's (typically Visa or MasterCard) network to the issuing bank's system, where the transaction is approved. An authorization code is sent to the merchant. The merchant submits batches of credit-card transactions at the end of the day to its bank (merchant account). Settlement then occurs between the merchant bank and the issuing bank through a combination of the card association and ultimately a payment network such as Fedwire.

Loans

A customer can take out a loan (the process is not shown in Fig. 91.1). There are numerous types of loans, including mortgage loans, car loans, credit cards, and installment loans. Taking out a loan requires filling out an application, which can be done at the bank, online, and at various loan brokers with whom the bank has agreements. After the application is complete, the customer's credit worthiness is verified. This requires obtaining information from external sources, and frequently involves credit scoring – using the bank's software or acquired from an external service provider. If the loan is approved, then it must be serviced. This is another touch point between the customer and the bank, requiring additional systems and potentially additional vendors.

A final issue is the generation of statements by the bank. Typically this requires sorting and printing transaction detail and is part of the core banking system. For some accounts that require specific balance levels and transaction usage across bank products, at least part of the process may be handled by an outside vendor. In these cases, transaction detail is sent to the vendor who determines if the product requirements were met, and if not the appropriate fees. This information is sent back to the bank to be included on the statements.

As is evident, there are numerous types of transactions, requiring interaction among a large number of organizations. The clearing process is similar or the same for many transactions. This is facilitated by standard formats for the required information, which makes automation both easier and more effective. The customer-facing portions of the processes are not as standardized. This causes integration issues that are discussed later.

91.3 Role of Automation in Community Banks and Credit Unions

It is generally accepted that investments in information technology (IT) can lead to improved firm performance and possibly competitive advantage. Research applying the resource-based view of the firm has shown that firms with better IT capabilities perform better financially than similar firms with less capable IT [91.12, 13]. This is particularly important for the banking industry, which invests heavily in IT and has increased investment from 6% of revenues in 2000 to 6.5% in 2001 [91.14]. Many bank chief executive officers (CEOs), however, are unsure of IT's impact [91.15], while others claim that these investments lead to increased services but decreased profits [91.16]. The issue is then: what drives successful automation?

91.3.1 Definition of Success

Examining what drives successful automation in community banks and credit unions requires defining success. Depending on the purpose of the automation, different definitions are appropriate. Under the resource-based view of the firm, the firm will focus on its unique, value-adding activities. Successful automation will enhance these activities and provide (or enhance) a competitive advantage. Firms can use IT to enhance firm value either by lowering costs or leveraging other firm-specific resources that differentiate the firm from its competition. Automation is successful here if it lowers the bank or credit union's cost structure or enables the institution to differentiate its products or services.

Traditional finance theory defines success (for an investment, such as an automation project) as having a positive net present value (NPV). Under this approach, any automation project where (in present value terms) the expected benefits outweigh the expected cost is successful – even if it does not support the bank or credit union's strategy.

There are other reasons for automation projects, including competitive necessity and regulatory compliance. Competitive necessity projects are done to catch up with the competition. The resulting automation will not result in a competitive advantage and may not deliver a positive NPV (unless the correct baseline is chosen) but must be done to remain in business. For these projects, the bank or credit union may go out of business if the project is not implemented. This should be the baseline for evaluating the project, not the firm's current environment. Likewise, regulatory compliance projects confer little benefit to the organization. For these projects, banks and credit unions need to minimize the cost of the project. The focus of this chapter is on automation projects that support bank or credit union strategy.

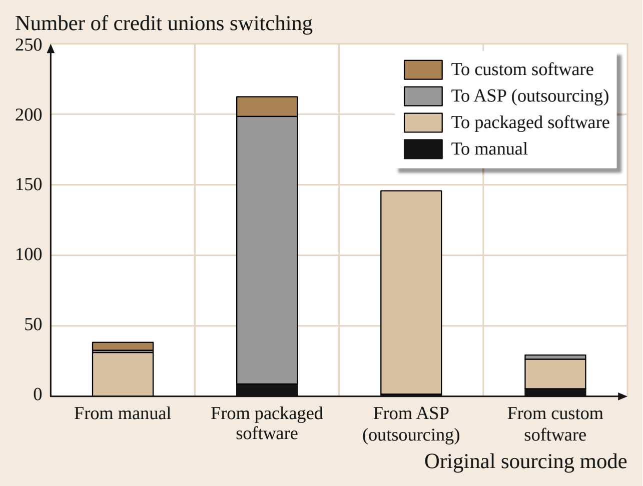

Fig. 91.2 Number of credit unions that switched how they sourced their core systems

As an example, consider SmallTown Credit Union (they asked that their real name not be used). SmallTown Credit Union (STCU) is a community credit union serving its home county and the surrounding three counties. It is located in rural, western North Carolina and historically has served blue-collar workers. It has approximately 15 000 members and assets of US$ 85 million. STCU's members are neither financially nor technically sophisticated. They want good, personal service, high rates on deposits, and low rates on loans. To serve these members, STCU invests minimally in automation. It uses packaged software for its core processing and was not an early adopter of Internet banking. It limits the services it offers electronically and adds new ones only when it is certain of demand by its current members. STCU's goals from technology are primarily to keep operating costs low and only second to offer new services for their members.

91.3.2 Core Processing and the Role of Sourcing

The core processing systems at banks and credit unions support their role as depository institutions and their role in the payment process. The automation includes demand deposit accounting, savings accounting, certificate of deposit and loan accounting systems, as well as the bank's general ledger system (every deposit or withdrawal affects the bank's balance sheet). These systems are basic transaction processing systems that track, and account for, each deposit, withdrawal, and loan payment made by customers. In addition, they calculate interest and fees. The demand deposit accounting systems are coupled with item processing systems that sort checks and deposits and calculate the totals by account. How these systems are sourced is a critical driver in their success.

In 2005, 32 new credit unions and 170 new (de novo) banks were started. Of the more than 8500 credit unions, almost 500 switched their processing mode (how their core systems are provided, Fig. 91.2). So, how small banks and credit unions automate their core processing continues to be of interest and is critical to their survival. Their ability to meet their strategic goals depends, to a large degree, on how they automate their core processing. Although the core systems support back-of-the-house transactions, they underlie the bank or credit union's ability to implement other systems that enable differentiation.

For banks and credit unions, automation of their core processing must be linked with their strategic goals. This automation will not necessarily reduce costs. In the 1960s and 1970s when banks started automating their core systems, processing capacity increased and profits for the banking industry as a whole fell [91.6]. For credit unions, based on data filed in their annual call reports, only 38% of the credit unions that automated their core processing between 1994 and 2002 lowered their operating costs on a cost per share account basis.

Banks and credit unions have three primary sources for automating their core systems:

1. Develop it and operate it themselves
2. Purchase packaged software and run it themselves
3. Outsource both the software acquisition and operation to a third party.

The sourcing choice is linked to the alignment between a firm's IT strategy and its business strategy [91.17]. Research on outsourcing has addressed the factors that result in successful outsourcing as well as what and why companies outsource [91.18–21]. The practices that determine management's perception of success are subject to debate, and different stakeholders have different perceptions of success. The differences are likely tied to different views of the firm's strategy and the impact of IT on that strategy.

Production economics [91.1] advocates outsourcing if the vendor has a production cost advantage. Transaction cost economics [91.1, 22] incorporates the cost of transacting business, including hold-up costs, and advises against outsourcing activities that are unique or require asset-specific resources. The resource-based view of the firm [91.23] argues that firms should invest in their core competencies and outsource the rest. For small banks and credit unions with limited IT capabilities, these theories argue for outsourcing core systems.

For small banks and credit unions much of the advice related to outsourcing is wrong. For those that choose to automate their core processing, how they choose to source their IT function affects their cost structure. It is related both to the number of products they offer and the number of channels through they are available (ability to differentiate). Finally it is tied to what they pay deposits (value to customers and members). Thus, how small banks and credit unions source their core systems is linked with key strategic decisions, such as their product and service offerings, their distribution channels, and their pricing.

Outsourcing core systems at small banks and credit unions is associated with higher operating costs, not lower operating costs. This contradicts much of the justifications given for outsourcing in the trade press and in prior research (e.g., [91.1]) – to lower costs. The specific vendor chosen also matters, since some software vendors are associated with significantly lower costs and others with significantly higher costs.

Instead of cost savings, outsourcing is associated with more services. Specifically, IT sourcing affects: the number of channels (both per member and total), the number of deposit products offered (total), the number of loan products offered (per member), and the price of deposits (both per member and total) [91.24].

This is not surprising. The application service providers (ASPs) have an incentive to develop new products (electronic channels) and to promote them to their clients. They are also able to develop the skills and processes to help their clients more quickly adopt new technologies, products, and services. Why credit unions that use packaged software lag those that use custom-developed systems is unclear. It could be due to skill development or to the importance that the credit union's executives place on using technology.

The higher costs associated with using an ASP (outsourcing) appear to be transferred, at least in part, to the customer through lower interest rates paid on deposits. This is understandable since members use more deposit-related services (and these services more frequently) than loan-product-related services. They are willing to pay for the additional channels to support their deposit products, but unwilling to pay higher loan rates for a product (loan) that they decide on once and then require minimal ongoing service.

A number of small financial institutions, especially small credit unions, do their core processing manually. While manual processing may be considered anachronistic, there are many instances, especially for smaller organizations, where automation does not make sense and manual processes are a valid approach. For small institutions, using manual processes is not more expensive, either in total or on a per-member basis, than using a computerized system. Identifying the optimal break point for when to switch from manual to automated processing is an interesting topic for future research, but appears to occur by the time an institution acquires 500 members/customers.

Approach

When determining how to successfully automate their core processing, small banks and credit unions must first determine the basis on which they want to compete. Those that decide to compete on cost need to

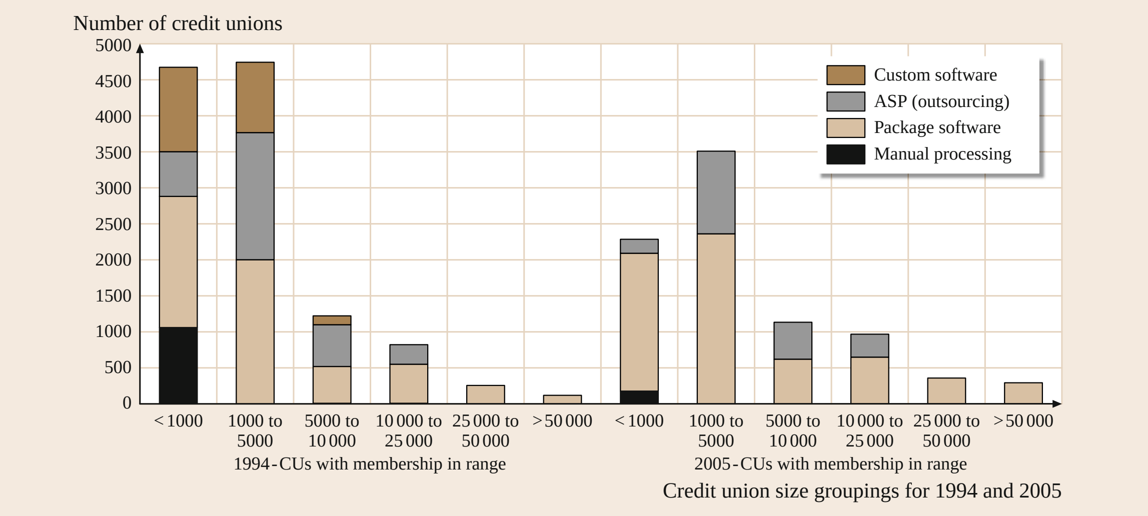

Fig. 91.3 Sourcing of core information systems by credit union size

minimize their overall cost structure (not just their IT costs). Given this choice, they need to assess whether to use manual processes or to automate. If they decide to automate, they need to decide whether to use packaged software or to custom-develop their own software. The decision to automate or use manual processing is tied to institution size. Only small credit unions with fewer than 1200 member use manual processing, and typically they automate well before reaching this size (Fig. 91.3). When automating, the trend is towards using packaged systems. Less than 1% of the credit unions use custom systems, and only 29 have switched to custom systems between 2003 and 2005. Once packaged software is chosen, selecting a vendor is critical. Again, there is a significant difference in operating cost depending on the software package/vendor chosen.

If the bank or credit union chooses to compete on service by offering more products and more channels to deliver these services, then using an ASP is the best approach. At this point, success becomes a vendor management issue rather than a technical issue. Choosing the right vendor and defining the contract are essential. Different ASP vendors are associated with different cost structures and number of channels. The same vendor will charge significantly different prices based on how well the bank or credit union negotiates the contract. Getting a good deal when the initial contract is signed is critical, since switching costs are high and the vendor will take advantage of this when it is time to renew the contract.

91.3.3 Internet Banking and the Role of Adoption

Bank and credit union's core systems automate the back-of-the-house. Banks and credit unions also automate front-of-the-house processes. These systems (such as ATMs and Internet banking) can possibly lower cost by replacing teller-based transactions. They also provide new channels for customers to access bank and credit union services, and they provide additional convenience for customers and members. Customer-facing systems automation can support either a cost-based or differentiation strategy.

For customer-facing systems, the key to success is user adoption. ATMs and Internet banking are classic examples. ATMs were implemented to enable customers to conduct financial transactions without using the tellers. The bank and credit unions' goal was to reduce costs by eliminating the need for tellers. For this to happen, customers had to be willing to use the ATMs. The more customers use these channels and the more transactions they used them for, the greater the (expected) benefits for the banks.

Internet banking has also been heralded as providing a competitive advantage and as being a competitive necessity [91.15, 25, 26]. Accordingly, banks spent 15% of their IT dollars on Internet banking in 2002 [91.27]. Yet, many banks question its profitability [91.28]. In fact, half of all US banks have no plans to offer Internet banking, with the most common reason given being an unclear return on investment [91.14].

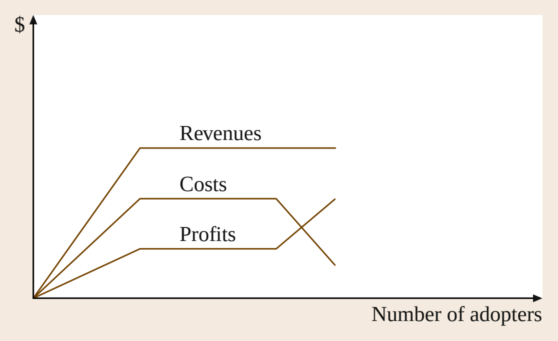

Fig. 91.4 Impact of Internet banking on costs, revenues, and profits

Internet banking is defined as a transaction-oriented system that enables a bank's customers to engage in online banking activities. Internet banking enhances a bank's offerings by providing its customers with 24/7 access to many of its services. The services available through Internet banking vary, but typically include informational account access (view balances and past transactions), funds transfers among accounts, bill payment, bill presentment, and some loan application and approval.

A *Booze* et al. study [91.26] claims that Internet banking has an expense rate that is one-third that of traditional banking with a per-transaction cost of US$ 0.01 versus US$ 0.27 for ATM transactions versus US$ 1.07 for teller-based transactions. For small banks and credit unions, this cost advantage is unlikely to occur. Instead, there is a stylized piecewise-linear relationship for costs, revenues, and profits driven by the number of Internet banking users (Fig. 91.4). An increase in the level of consumer adoption increases revenues, costs, and profits until a *saturation* level is achieved. Additional adopters in excess of the saturation level do not add further to profit, revenue or cost until a second breakpoint is reached. The cost and profit models experience a change at this second breakpoint, but revenue does not. In the cost model, after enough customers adopt Internet banking, a bank's costs begin to decrease. Correspondingly, profits trend upwards after this point.

The initial cost increase comes form a combination of more transactions, more accounts, and higher deposits (and therefore higher interest expense). In particular, banks with Internet banking have a higher growth rate in the number of accounts (14% higher for demand deposit accounts (DDAs) and 32.8% higher for savings accounts). In addition, Internet banking is associated with a larger average deposit size per account of about US$ 800 at a median bank. This indicates that, while new customers are drawn to the bank, existing customers also are doing more business with their bank. This increase in bank activities necessarily increases costs. Despite this increase in transactions, the actual volume of transactions performed using Internet banking relative to more traditional transactions is typically quite small. Correspondingly, reductions are unlikely in the fixed infrastructure costs related to traditional transactions (e.g., the number of tellers employed or ATMs operated) unless a large number of customers adopt Internet banking.

Improved profits initially result from increased revenues despite increased costs. These improved revenues are the result of an increase in the bank's interest income through soliciting new customers and getting more business from previous customers as well as more fee-based bank services being sold. Previous research finds that consumers who use internet banking (IB) are more lucrative. They generate above-average revenues and are more profitable [91.29]. In particular, IB customers have significantly higher mortgage and loan balances, and they use twice the number of other financial services products [91.14]. The impact of Internet banking usage on revenue and profit is relatively small and typically results in an increase of less than 5%.

For the majority of small banks and credit unions reaching the Internet banking user adoption level breakpoints constitutes a major undertaking. For 25% of the small banks, reaching the breakpoint number of

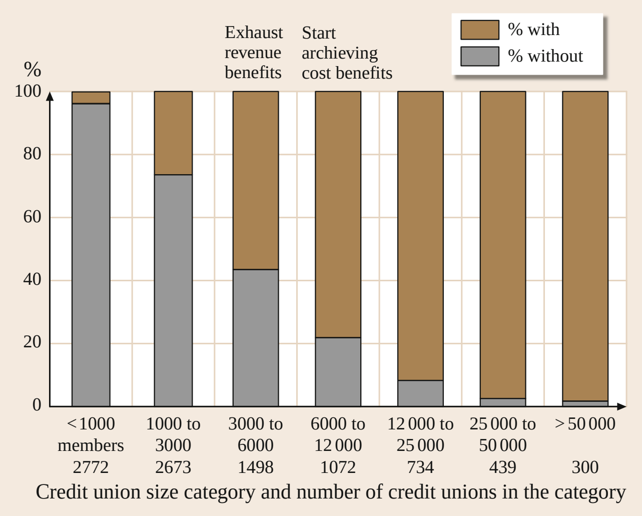

Fig. 91.5 Percentage of credit unions with internet banking by size

adopters requires over half of their customers to adopt Internet banking. For credit unions, over half do not have enough members to reach the first breakpoint. For another 25% of small banks, this requires a customer adoption level exceeding 25% of its customer base (Fig. 91.5). Doing so also takes time – on average over 1.5 years for those that can and do reach it. For a larger number of small banks and credit unions the second breakpoint exceeds their customer base. This implies that small banks and credit unions have to be very careful when implementing new customer-facing technology. To be successful requires getting a significant portion of their customer base to adopt.

Approach

When implementing customer-facing automation projects, banks and credit unions need to take a disciplined approach. First, they need to determine whether the project makes sense. This entails assessing the fit with their strategy. Customer-facing systems will not lower cost, so the institution must want to differentiate its services based on this project. Assuming the project fits with the strategy, it may still not be feasible if the institution does not have enough customers or enough customers who will be interested in using the new service. Finally, since the increased revenues come, in part, from existing customers deepening their relationship with the bank or credit union, it must offer enough additional products and services to take advantage of this additional business.

If the project fits with the organization's strategy and they have a large enough customer base, they will need to market the new services effectively. This requires a different strategy for different target markets. If the new automation requires a significant change in how the customer uses the bank or credit union services (as was the case with ATMs and Internet banking), they should consider paying the customer to use the service. If customers will be paid to use the service, it must be done carefully. Banks and credit unions that paid customers to use ATMs saw increased adoption. Some banks and credit unions that paid customers to create Internet bank accounts saw people create accounts, but not necessarily use them.

If the automation project is innovative, the customers will need to be trained to use the new system. Younger customers may be able to learn online, but older customers and those whose primary channel is the branch will need more personal training, probably at the branch. Finally, the banks and credit unions need to listen to their customers who are not using the new service or channel to determine why, and then to either modify the service/channel or update their marketing and training materials.

Even with an effective marketing program and a good training process, the banks and credit unions will face a customer adoption process. Customer adoption will follow an S-curve. Effective marketing and training may make the curve steeper, but identifying and supporting early adopters is critical. Early adopters of an innovation typically have the most interest and willingness to pay for the innovation. Later adopters are typically less inclined toward the innovation. Relative to new services, this implies that customers who adopt them early on are likely to be the most profitable, and as more and more people adopt, the incremental revenue per customer will diminish.

Sourcing Impact

As with core systems, Internet banking, and future customer-facing automation projects, how the automation project is sourced impacts success. The sourcing choice changes the cost structure for the service. It affects the implementation timing and potentially supports the customer adoption process.

When the banks and credit unions use an Internet banking service provider, their variable transaction cost structure is different from that for banks that develop their own Internet banking system. To implement Internet banking, there is still a fixed, but small, one-time cost for the system in the US$ 20 000–40 000 range. Once the system is installed, there is a nominal fixed monthly fee (less than US$ 1000) plus a fee for each Internet banking customer as well as fees for various transactions. The total fee for each customer depends on the services the customer is signed up for (e.g., bill-pay) and how much historical information the bank retains (i. e., it costs the bank more if the bank lets its customers view deposits and withdrawals from 2 years ago than if the maximum a customer can go back is 6 months). This fee can range from US$ 2 to US$ 15 per customer per month. Additional fees also are charged for most transactions, including signing up a new Internet banking customer and for a customer making a payment. Enquiries are free. This cost structure makes most of the bank's costs variable. This lowers the risk of implementing Internet banking, but also makes lowering the bank's overall operating costs more difficult. The operational risks typically associated with innovation are mitigated by the use of a vendor, but banks that use this service are unable to physically distinguish themselves from other banks using the same service.

91.4 Emerging Trends and Issues

There are a number of trends and issues affecting small banks and credit unions. The US Federal Government continues to impose additional regulations related to tracking customers and customer activity. Customers continue to shift their payments to electronic forms. New technologies and channels, such as Web 2.0 applications, continue to emerge, and automation to support these trends is leading to banks and credit unions using more vendors, with the accompanying issues involved in integrating these systems.

91.4.1 Role of Integration

Implementing new products requires new systems. Implementing new channels requires new systems. Implementing new processes requires automation. Most community banks and credit unions do not have the skills to automate this on their own. They are either outsourcing their processing to ASPs and other vendors, or they rely on packaged software. To automate a new product, channel or process requires identifying the appropriate provider and then implementing the system and integrating it with the existing systems.

The integration required for basic functionality is addressed by the vendor; for example, to implement Internet banking requires integrating the Internet banking software with the bank or credit union's core processing system, and that provided by the vendor. When the integration is not central to the automation project, however, it is frequently omitted by the vendor and not examined (at least initially) by the bank or credit union.

Where this has been particularly problematic is with basic customer information. When a customer changes their email address in one channel, they expect that it be changed everywhere in the banks systems. Because of the numerous systems and vendors, this frequently is not done. Even when the bank or credit union uses a single vendor (e.g., FISERV) their products may not be completely integrated, because they have frequently purchased the software from another vendor (or purchased the vendor to acquire the software).

This type of integration becomes a vendor management issue more than a technical issue. The integration issues need to be part of the software/vendor selection and contracting process. Service level agreements centered around integration are difficult, since the future systems are not identified. User group pressure, however, appears to be effective in getting the vendors to focus on this issue. This implies that, when selecting a vendor, banks and credit unions need to choose those large enough to have an effective user community.

91.4.2 Regulation

The US Federal Government is increasingly regulating financial institutions' operations. The USA Patriot Act, the fair and accurate credit transactions (FACT) act plus additional rules by the Securities and Exchange Comission (SEC), Financial Accounting Standards Board (FASB), and others add to the regulatory burden. New laws, such as H.R. 3012, The Fair Mortgage Practices Act of 2007, are introduced and existing regulations change each year. These regulations are disproportionately burdensome for small financial institutions, and some believe that they will drive small banks out of business [91.30].

Automation projects to fulfill regulatory requirements are difficult, because they usually have a fixed deadline for implementation, which can be unrealistic. These automation projects will not provide a competitive advantage. They will not support strategic efforts. They will not reduce costs (except through penalty avoidance). Typically, the goal is to get them in as cheaply as possible. The risk is that this will lead to higher costs long-run as the capabilities need to be integrated throughout other systems. This is particularly true for regulations requiring monitoring suspicious activity, where the bank needs to identify and analyze a picture of a customer's entire relationship with a bank.

91.4.3 Shift From Paper to Electronic Payments

The number of paper checks and the value of those checks are finally decreasing as consumers and businesses shift to electronic payments. The back-end settlement infrastructure is largely automated, but new front-end technologies – new payment channels – continue to emerge. Using mobile phones for payments has been available in Japan for a number of years, but is in its early stages of adoption in the USA. Small banks and credit unions again face a decision of whether they want to offer their customers and members a new channel.

The shift to electronic payments, however, is bypassing person-to-person payments. PayPal allows person-to-person payments, but has not had a significant effect on the number of paper-based transactions. Mobile technologies offer the possibility of allowing individuals to make and receive payments. Citigroup offers this service through Obopay, and is currently paying its customers to sign up for the service. Obopay is similar to a prepaid credit card, but both parties must use the service.

91.4.4 Emerging Technologies – Web 2.0

Web 2.0 technologies for social networking appear, at first glance, better suited for enhancing internal bank and credit union operations. Communities of loan officers, compliance personnel or packaged systems users would help each group more efficiently and effectively carry out their duties. They would provide a place to get help, gain insights, and kvetch. They could either be operated by the bank or by independent third parties and would not need to integrate with existing system.

Banks, however, are exploring the use of social networking as a front-end to customer education and interaction. Wells Fargo is leading the way, and if it successful, it will pressure small banks and credit unions to follow suit. Wells Fargo initially created a site on Second Life. The site provided both games and financial education. To gain more control over the customer experience, they left Second Life and started their own virtual world, Stage Coach Island.

On Stage Coach Island, participants can network with each other and do activities together, such as motorbike racing and parachuting. They can learn about financial products and services, ostensibly to develop financial responsibility. Although there is little Wells Fargo advertising, it has the potential to provide Wells Fargo with a wealth of information about their customers or potential customers.

At the moment, small banks and credit unions most likely do not have the skill set to duplicate Wells Fargo's efforts. Although there is vendor-supplied software for developing virtual worlds, there are not vendor-supplied virtual worlds available for banks and credit unions to brand and customize for their customers and members.

91.5 Conclusions

Small banks and credit unions face unique considerations when automating. They have to keep up with larger institutions, but do not have the resources to execute these projects on their own. This causes them to rely on external vendors, which raises integration issues, especially for customer-facing systems. A changing business environment and new technologies require that small banks and credit unions continue to invest in automation, but to be successful they will need to ensure that these projects support their strategy and that the approach is appropriate for this strategy.

92. e-Government

Dieter Rombach, Petra Steffens

e-Government in its most generic form refers to the automation of government processes and services by using modern information and communication technologies, usually – but not necessarily – in combination with web technology. The transition from paper-based administrative workflows to electronically supported process chains involving a multitude of stakeholders (in particular, government agencies, citizens or companies) is a key driver of today's e-Government policies. Whereas in their early manifestations, e-Government efforts were primarily geared towards improving internal administrative performance, today's focus is on increasing the overall quality of government services. The aim is to improve the living conditions of citizens and to create a favorable climate for business.

This chapter provides a short introduction to the basic concepts of e-Government, explains how e-Government evolved over the last 10 years, gives an overview of the dimensions on which the design and implementation of successful and sustainable e-Government services has to proceed, and outlines some future challenges for e-Government.

92.1 Automating Administrative Processes

The 20th century has been the era of digital revolution. Information and communication technology (ICT) has deeply affected business processes, service provisioning, production, as well as the private habits and activities of the citizens in our modern societies. In fact, ICT has become an integral part of most of today's products and services.

ICT has also had a significant impact on the way in which government agencies perform their tasks. The standard inventory of government automation today comprises email, interactive websites, downloadable forms, and sometimes information upload. However, for most governments the level of automation and integration is lagging behind the computerization of businesses. This can be observed in all kinds of government activities and services: internal workflows as well as processes between government and its external partners (citizens and business). Today's challenge for government agencies all over the world is to reach a seamless integration of their own work processes with those of their internal and external partners. This concerns the following types of collaboration:

- Government-to-government (G2G): interactions inside or between government agencies
- Government-to-citizen (G2C): services that government delivers to its citizens
- Government-to-business (G2B): workflows between government and business.

Many modern governments have understood that through the use of electronic media they can increase the efficiency, quality, and transparency of their services and thus increase the attractiveness of their national economy in a globalized world. Solutions developed to this end are summarized under the umbrella of e-Government.

This chapter describes how e-Government evolved over the last 10 years, provides an overview of the dimensions which need to be addressed in the design and implementation of successful and sustainable e-Government services, and outlines some current challenges for e-Government.

92.2 The Evolution of e-Government

The beginnings of e-Government were in the late 1990s when ICT, especially the use of online media, was recognized as an important means to improve the efficiency and quality of government services. The use of ICT was often inspired by achievements made in e-Business, which demonstrated that doing business online could help increase the efficiency of business processes in a company as well as between companies.

Since 1995, *Gartner* has used the concept of *hype cycle* to describe the relative maturity of technologies, IT methodologies, and management disciplines. Hype cycles distinguish five phases [92.2]:

1. *Technology trigger*: The first phase of a hype cycle, which is provoked, e.g., by a product launch or other event that generates significant press and public interest
2. *Peak of inflated expectations*: The second phase, which is characterized by overenthusiasm and unrealistic expectations
3. *Trough of disillusionment*: Technologies fail to meet expectations and quickly become unfashionable
4. *Slope of enlightenment*: Despite a decrease in public and press interest, some businesses keep up their in-

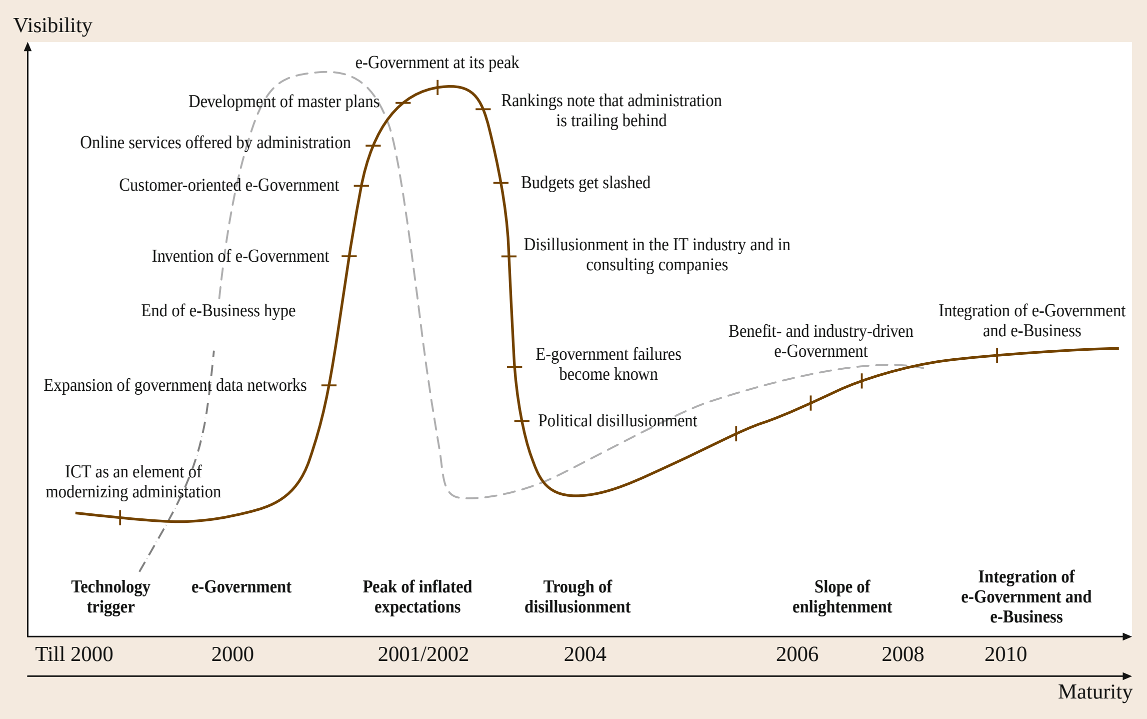

Fig. 92.1 Evolution of e-Government example. Note: The *dotted line* shows the development line of e-Business (after [92.1])

terest and experiment to understand the benefits and practical application of the technology

5. *Plateau of productivity*: The technology becomes increasingly stable; its benefits become widely demonstrated and accepted.

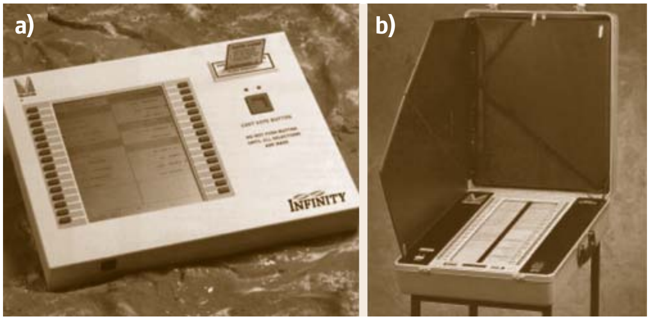

Fig. 92.2a,b Examples of electronic voting machines from around the world: **(a)** Infinity voting terminal (courtesy of Microvote General Corporation), **(b)** MV-464 voting station (courtesy of Microvote General Corporation)

Adapting Gartner's hype curve to the evolution of e-Government in Germany, *Büllesbach* has drawn an exemplary development line of e-Government [92.1], as can be observed in analogous forms in many economically developed countries (Fig. 92.1). Throughout the 1990s, ICT was mainly regarded as a means of modernizing administration by facilitating communication and workflows between state agencies. For Europe, this is illustrated by the e-Government country fact sheets, which the European Union publishes yearly for 33 European countries [92.3]. As a consequence of supporting internal work processes with ICT, new government data networks were established and the coverage and capacity of existing ones were increased.

By the beginning of the millennium, the concept of e-Government made its debut, implying a shift in focus: Turning away from the primarily internal use of ICT, governments started to perceive benefits in applying new technologies to offer electronic services to their clients (e.g., electronic voting machines (Fig. 92.2)). Early applications developed at that time mainly focused on citizens and were usually limited to providing access to information, allowing simple forms of interaction such as exchanging e-Mails or using feedback forms. e-Government projects at the time were often conducted separately from each other, leading to isolated and incompatible solutions.

To overcome this situation, governments started to realize the need for a more systematic approach: e-Government master plans were thus developed that put existing and planned projects under the umbrella of a common strategy. With the development of master plans that gave rise to high expectations, e-Government also became more visible on the political agenda and reached its hype peak. Expectations were dampened though, when it became clear that often e-Government lead times were incompatible with politicians' striving for timely success and that underestimation of a task's complexity and of the challenges posed by its political context (e.g., federal structures with complex decision processes), not only let projects overrun time and budget but also failed to evoke acceptance [92.4]. A prominent case in point is the German FISCUS (Föderales Integriertes Standardisiertes Computer-Unterstütztes Steuersystem – federal integrated standardized computer-supported tax system) project, which aimed at developing uniform tax software for the fiscal administration in Germany, but was stopped and entirely reoriented after 13 years without producing the expected results [92.5]. As a consequence, e-Government budgets were cut and failures of e-Government projects became public. In addition, it was recognized that citizens, who had so far been the primary target of e-Government efforts, did not access e-Government services at a sufficient rate to realize the expected return on investment.

This political disillusionment was overcome mainly by two shifts in focus: first, technology as a major driving force for developing new solutions was replaced by the goal of creating customer benefit; second, companies, which have more frequent and regular relationships with government agencies than citizens, moved into the focus of attention and became the main target for e-Government. In Germany, this shift in focus has occurred under the heading of *benefit- and industry-driven e-Government* [92.6]. During this phase, the integration of government and industry processes became the main subject of e-Government efforts, ultimately aiming at the seamless integration of e-Government and e-Business on the ICT as well as on the process level.

A common way to describe a project's or even a country's maturity with respect to e-Government is to position it on a scale comprising four phases, each indicating the degree to which the potential of ICT is utilized to deliver public services electronically [92.7]:

- *Presence.* The emphasis in this phase is to offer online static information about government agencies and their services. In this phase, e-Government ser-

vices are often limited to a presence on the web, providing the public with information similar to that of a brochure or leaflet. Meanwhile most public web sites have gone beyond this stage.

- *Interaction.* Solutions in this phase typically include simple forms of interaction; for example, citizens can ask questions and receive answers via e-Mail, download forms or search government databases. The interaction phase is exemplified by the web-based system FLO*rlp* – Land Parcel Information Online for the German State of Rhineland-Palatinate, which supports farmers in applying for agricultural subsidies by providing them with precise information on the location and size of their cultivated areas and by allowing them to visualize areas by means of maps and aerial photographs [92.8] (Fig. 92.3).
- *Transaction.* Conducting complete transactions online, such as applying for passports, submitting tax declarations, paying taxes and fees, or submitting bids for public tenders, are supported by systems in the transaction phase. These solutions are considerably more complex because often they have to address technically challenging issues, e.g., concerning security and privacy. For instance, digital (electronic) signatures or equivalent methods of identification are necessary to enable legally binding administrative acts. Often government even needs to pass new laws to enable paperless transactions. An example of an e-Government solution requiring authentication of users through digital signatures is the German federal procurement solution e-Vergabe [92.9]. Additional examples of transactional sites are shown on the following pages (Figs. 92.4–92.7).
- *Transformation.* Solutions belonging to the transformation phase represent the most advanced form of e-Government. They comprise entire process chains between government and its clients. The services in the back office are completely integrated so that boundaries between different tiers of administration (e.g., federal versus state), departments or agencies are removed. The solutions are highly complex and require the governmental bodies to be reorganized in a new, process- and service-oriented way. This stage harnesses the benefits of ICT to their fullest extent. Currently, solutions in the transformation phase are still rare. However, within the European Union, a major boost for e-Government projects taking them to the transformation phase is expected through the EU Services Directive. By 2010, this regulation requires all member countries to offer points of single contact and handle all processes by electronic means for service companies which want

to set up businesses [92.10]. Also, many countries already offer comprehensive portals for business and citizens to access public services, such as the *UK Directgov* portal (Fig. 92.7).

In order to secure the success of e-Government developments, implementation activities need to proceed on four dimensions. In the following section, we will look at each of these dimensions in turn.

92.3 Proceeding from Strategy to Roll-Out: Four Dimensions of Action

Benefit-driven e-Government projects beyond the communication phase are characterized by a high level of complexity. They usually span multiple and often autonomous organizations (public agencies and companies), involve heterogeneous IT infrastructures, and concern numerous target groups and stakeholders. They have to meet conflicting requirements, face complex technical dependencies, and have to respect different legal constraints. Similar challenges also have to be faced in other IT projects. What makes e-Government projects special though is that they usually have to cope with a combination of numerous inhibiting factors and that IT strategies and decisions in the public sector are closely related to political constellations, which in democratic states may change from one election to the other. For the successful execution of e-Government projects, it is therefore essential to:

- Develop a clear view of strategic objectives
- Design projects so that tangible results become visible at an early stage for all parties
- Involve users and stakeholders from the onset
- Handle architectural tradeoffs in a transparent way
- Ensure sustainability of the solution (in terms of legal aspects, process and technology used)
- Manage and minimize risks for all parties involved
- Manage change processes for all parties involved.

In order to accommodate these aspects, the design and implementation of benefit-oriented e-Government should proceed on four dimensions:

- Strategy
- Processes and organization
- Technology
- Project and change management.

We will now look at each of these dimensions.

92.3.1 Strategy

On the strategic dimension, a master plan has to be created which addresses the following topics.

Political Objectives Pursued by e-Government

There are different objectives that can be the driving force behind the implementation of e-Government; for example, e-Government can be used as a way to enhance a community's attractiveness for citizens and business, as a means to increase the transparency of democratic processes or to increase the efficiency of the administration. In addition, the way in which political and administrative institutions on different levels of government interact needs to be spelled out. In countries which are organized in a centralized way, a more-or-less top-down approach is feasible, whereas in countries based on a federal system there is an obvious need to establish structures that regulate the complicated interplay of different stakeholders and help to resolve controversial issues in a timely manner.

Targets Addressed by e-Government

Based on the high-level political objectives, the primary groups which are to be targeted by e-Government can be determined and prioritized, i. e., government itself, citizens or companies. In order to arrive at an operational level, these groups need to be broken down further; for example, if a government decides to put the focus on citizens, it may put emphasis on subgroups such as elderly persons, immigrants or families. Similarly, when targeting business, a decision can be made on the

basis of industry sector (e.g., automotive versus chemical), company size (large corporations versus small and medium enterprises), or significance for the regional economy.

Technical Infrastructure and Technological Requirements

In most cases, the existing heterogeneous technical infrastructures provide the framework within which new developments have to be initiated. Therefore, IT infrastructures and technologies relevant to e-Government have to be surveyed and evaluated, and then political decisions regarding the further development of technologies in use have to be made. In particular, this concerns the decision in favor of commercial or open-source technologies, the decision between custom-made solutions versus adapting and reusing solutions originating from other governments, or the decision between running your own infrastructure versus outsourcing ICT. In addition, the standards to be followed have to be specified. This concerns both technological issues, e.g., system architecture or usability, as well as the development process itself. An example of a standard regarding system architecture is the SAGA (Standards und Architekturen für e-Government-Anwendungen – standards and architectures for e-Government applications) standards framework published by the German federal government. SAGA pursues the following aims [92.11]:

- Interoperability – ensuring a media-consistent flow of information between citizens, business, the federal government, and its partners
- Reusability – establishing process and data models for similar procedures when providing services and defining data structures
- Openness – integrating open standards into applications
- Reduction of costs and risks – considering investment-safe developments on the market and in the field of standardization
- Scalability – ensuring the usability of applications as requirements change in terms of volume and transaction frequency.

Fig. 92.7 UK e-Government site for a number of different services in the UK (with permission of Crown, http://www.direct.gov.uk/en/index.htm)

SAGA is meant as a guideline for the design of e-Government architectures, addressing decision-makers in public IT management as well as developers of e-Government solutions.

An example of a standard focusing on the development process itself is the lifecycle model V-Modell XT, which is the recommended standard for the federal German administration and for defense projects. V-Modell XT provides a reference process describing the activities and results that have to be produced during software development projects. It aims at improving project transparency, project management, and the probability of project success [92.12].

Focal Application Areas

Prioritization of application areas is essential for the success of an e-Government project; for example, if the political objective is to make government more efficient, a decision has to be made concerning which government processes will benefit most, e.g., procurement, skill development or management of geographic data. Depending on the focal application areas, the necessary base technologies can be identified (e.g., workflow applications, geographic information systems, portal technology).

Roadmap

Based on the focal application areas, highly visible key projects are identified which promise immediate benefits and can therefore help in securing further political support. For further implementation of the strategy, key projects and the planned enhancements of infrastructure and of base technologies are plotted on a roadmap. A roadmap shows the main steps of how to set these projects on track by defining a schedule, allocating financial resources, assigning responsibilities, and defining critical success factors [92.13]. Roadmaps are mid- to long-term compared with the short- to mid-term electoral cycles of politicians; thus, success will most probably not be reaped by those who initiated the developments.

Wherever possible, the decisions to be taken on the dimension of strategy should be based on empirical evidence. This evidence may, for example, come from surveys among stakeholders, such as those conducted by the Fraunhofer Institute for Experimental Software Engineering (IESE) or the Technical University of Munich amongst industrial companies to identify G2B processes and determine their e-Government potential [92.14, 15], return on investment analyses (ROI) [92.16] or quantitative evaluation of technology acceptance [92.17].

92.3.2 Processes and Organization

Frequently, IT solutions are used to support existing workflows and their corresponding organizational structures. This may lead to some gains in efficiency and quality, but does not lead to the large-scale benefits that could be achieved if work processes and complex process chains involving different organizational units were truly optimized and reengineered. Take, for example, procurement processes in a distributed public administration. As long as IT is only used to support each agency in their traditional procurement processes, the economies of scale to be realized from bundling demands cannot be realized. Bundling of demands across agencies, on the other hand, requires a new setup of workflows and responsibilities: new units have to be established that are responsible for determining demands, negotiating contracts, and maintaining catalogues.

The identification of process chains which would yield high benefits for all stakeholders if transformed into an e-Government solution is done on the basis of potential analyses and is part of strategy building. Once process chains have been identified, ranked, and reengineered, they are scrutinized for common building blocks which require the same functionality. Lately, methodological frameworks for process modeling have been developed, which offer public-sector-specific process building blocks [92.18].

The challenge of process reengineering in the public sector is to overcome the boundaries between different organizational and functional units and between government and its clients. This may imply a shift of responsibilities, the adoption of common technical platforms and exchange formats, as well as cultural assimilation. Facing these challenges requires a high level of motivation and will only succeed if it finds a prominent place on the political agenda.

92.3.3 Technology

At present, IT systems in the public sector (like years ago in the business sector) are still characterized by heterogeneous IT infrastructures, a multitude of different applications, incompatible data formats, and human–computer interfaces which are difficult to use. However, for the realization of process-oriented e-Government it is essential that data and information can be exchanged smoothly and securely among agencies and between government and citizens as well as between government and businesses. In addition, for economical reasons, it has to be ensured that software architecture allows for reuse of legacy applications and promotes reuse of newly developed components and data.

It is mainly the disciplines of IT architecture, IT security, and usability which address these technological challenges. In the remainder of this section, we will look at recent developments in each of these fields.

Many of the challenges concerning heterogeneous IT landscapes and redundant services and data are addressed by the service-oriented approach to IT architectures [92.19, 20]. On the level of technology, this approach can be seen as a counterpart to the process-oriented approach described in the previous section. Service-oriented architectures (SOA) stand for a management concept as well as a comprehensive design principle for IT infrastructures. They lead to IT infrastructures which are able to adapt themselves easily to the changing requirements of the application domain. The salient feature of service-oriented architectures are software building blocks (services) which can be recombined relatively easily into new or more comprehensive solutions in support of new or more complex business processes. Services communicate via standardized exchange formats and interfaces. Conformity with standards ensures that different business processes which include identical activities can make use of the same basic building blocks. Thus, redundant development efforts can be avoided and the implementation of modified processes can be accelerated.

Facing an unprecedented ability of modern ICT to collect, track, and analyze personal data (e.g., telecommunication records, flight records, credit-card payments, or e-Mail communication), many citizens and companies hesitate to contribute further to their data trail and therefore avoid e-Government services. A means to counteract such fears and build trust is privacy policies for the protection of personal data and privacy. Examples are the recommendations of the Organization for Economic Cooperation and Development (OECD), which cover a large number of organizational and technical issues, spanning data transparency to data parsimony [92.21]. Especially in the context of e-Government, where trust is of utmost importance, instruments are employed which help to ascertain users' identity (authentication) and to protect private data.

Common instruments used for authentication are digital signatures and digital certificates [92.22]. In some countries, including the USA and countries of the European Union, these provide a legally binding authentication method for the seamless electronic execution of administrative transactions. Usually, they require special hardware devices (card readers) as well as a public-key infrastructure (PKI), which comprises organizational and technical elements to certify the owner's identity [92.22]. Despite their technical maturity, digital signatures still lack wide acceptance, because users shun the necessary organizational and technical efforts.

Alternative signature mechanisms have therefore been proposed that do not require a PKI infrastructure. An example is Pretty Good Privacy's (PGP) web-of-trust approach [92.23], which is based on mutual trust in a community of peers. However, this approach lacks central control, which is the main reason why governments are reluctant to adopt it. To facilitate the use of digital signatures, the integration of common chip card applications, such as credit cards and health insurance cards, with citizen cards is currently pursued. A positive example for enhancing commonly used chip cards into devices for personal authentication is the Austrian citizen card (Fig. 92.8). However, wide acceptance of citizen cards will ultimately depend on striking a balance between costs, efficiency, dependability, and convenience.

Adequate usability is a minimal requirement for achieving convenience. Whereas e-Business solutions usually target specific user groups, most e-Government solutions, especially those for citizens, must be usable for everyone. Generally, no specific training can be provided. In fact, governments are often obliged by law to provide services without discrimination to the population at large and to counteract the danger of digital divide [92.24, 25]. In particular, accessibility for users with special needs has become a major requirement of many national e-Government projects [92.26].

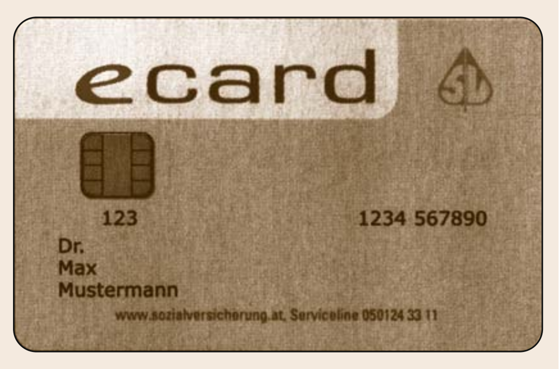

Fig. 92.8 Austrian e-Card, usable as health insurance and citizen card

In formulating e-Government policies, master plans, and project objectives, IT security and accessibility issues have moved center-stage over the last few years. However, it is often overlooked that these requirements represent conflicting goals, which have to be reconciled on the level of software architecture. A method especially developed to help in this endeavor is the architecture tradeoff analysis method developed at Carnegie Mellon University. It has been designed especially to identify and mitigate potential risks emerging from conflicting interests with regard to the characteristics of an IT system [92.27].

92.3.4 Project and Change Management

Several project lifecycle models and project management methods have been proposed, which have a special focus on the requirements of public-sector IT projects [92.12, 28]. It is not our intention to provide a comprehensive account of project management or software engineering issues here. However, there are certain aspects of project management which seem crucial for the success of e-Government projects, for example achieving consensus among stakeholders and delivering measurable results at different milestones of a project. The following aspects of project management address these issues.

Project Design

Project design refers to the high-level structuring of a project into phases, milestones, and additional control points. Splitting a project into phases, e.g., design, implementation, and testing, belongs to the standard tasks of a project manager. What is not state-of-the-practice yet is to perform measuring activities which assess critical success factors in these phases. Success criteria can refer to technical requirements such as system performance or interoperability, to usage criteria such as user acceptance, but also to economical aspects such as financial savings or shortening of processing time. Success criteria need to be set up consensually at the beginning of a project and have to be monitored throughout system operation. Project design ensures that these critical factors can be validated early enough in the project so that adjustments to software design can also be made early. Depending on the degree of innovation, the degree of precision and concreteness of project objectives, and the degree of user interaction, phases should be devoted to proof of concept, prototype building, different field tests with representative users and stakeholders, and finally a staged roll-out.

Communication Management

The electronic support of complex administrative processes usually involves a large number of stakeholders and users. Often, these groups have divergent interests, which can lead to considerable friction and project delays. Managing communication proactively is of paramount importance to facilitate consensus building. It is needed (a) to obtain a transparent picture of stakeholder interests, (b) to establish clear communication and decision procedures, and (c) to plan for appropriate actions. Apart from detecting and resolving potential conflicts, communication management also aims at ensuring project support by proactively informing stakeholders, politicians, and the public on project status and plans. It thus plays a vital role in the process of creating technology acceptance.

Change Management

Process orientation, which is at the core of many of today's e-Government efforts, is often opposed to the traditional principle of vertical line organization of administration. Only if processes, structures, and attitudes change can the benefits of automating process chains materialize. Therefore, project management has to put special emphasis on preparing the ground for change and on implementing change in a transparent and cooperative way. There are two instruments which seem to be key in change management processes: guiding coalitions and user participation.

Guiding coalitions are groups which are able to direct a change effort. For public-sector projects, guiding coalitions should be composed of the following individuals.

Political Sponsors. Securing broad support among political leaders is crucial to ensure financial continuity for a program, as transformation processes often span electoral cycles. Political support will also be essential if legislation or regulatory changes are needed.

Line Managers. Line managers are responsible for correct execution of administrative processes. They have the power to define how an administrative procedure is implemented on the operational level. Often they also have budget responsibility. Usually, they survive electoral cycles and can thus facilitate continuity.

Employee Champions. Employee champions are usually senior officials with long-standing expertise, who lend credibility to the cause. They act as early adopters and thus help to motivate others and reduce fears and objections. They are least exposed to the changing winds of electoral cycles.

Independent Advisors. To support complex decision processes and conflict resolution, independent advisors, for example, from national research institutions, are an indispensable part of the coalition. They bring expertise on the levels of strategy, technology (state-of-the-art and future), legislation, organizational and process analysis, and redesign. Moreover, externals are open to promising options that threaten current structures.

In implementing change, the guiding coalition relies upon a project team which combines technical, organizational, methodical, and legal expertise.

Besides setting up guiding coalitions, users should be given the opportunity to take part in the change process; for example, users can be included in project teams as on-site customers or can contribute to designing and optimizing a solution by piloting it at different stages in a project. In general, those who are affected by the change need to be informed on a regular basis and should be given a chance to express their opinion and concerns, for example, in web blogs, at regular information events or through one-on-one counseling [92.29].

92.4 Future Challenges in e-Government Automation

In the previous sections, we gave an overview of the evolution of e-Government and explained the actions necessary to leap forward from political vision and strategy to practical solutions. However, despite many inspiring examples and promising approaches, e-Government development still lags behind the development of ICT in business. This is due to the specific characteristics of the public sector and partly, but to a minor extent, to technological issues.

In the following, we will look at some of the issues, which we consider crucial for the transition from an insular and function-oriented government with a high degree of data and systems redundancy to an ICT-empowered, process-oriented, and cohesive type of e-Government. We will distinguish two types of challenges which e-Government initiatives and the technology sector have to face: political challenges, which require action on the level of policy and politics, and engineering challenges, which require the development of new methods or the adaptation of known approaches. In the remainder of this section, we will look at each of these issues in turn. However, we will not look at the management challenges of applying and enforcing well-established software engineering practices (see, e.g., the e-Government manual of the German Federal Office for Information Security [92.30]).

92.4.1 Political Challenges

In many countries, the landscape of e-Government solutions is characterized by heterogeneous and incompatible approaches and technical solutions. This is mostly due to the fact that administrative units often act independently from each other and pursue their own political agendas. In order to overcome the situation, it is necessary both to establish standards of technical interoperability and to install e-Government representatives, e.g., national chief information officers (CIOs), who are equipped with enough political clout and resources to make these standards mandatory across departmental boundaries and across different levels of administration (e.g., community, state, and federal). A country which has successfully implemented the concept of a national CIO in charge of e-Government is Austria, which as early as 2001 installed a national CIO directly reporting to the chancellor of the federal republic [92.31].

In many cases, e-Government projects span a large number of years, which may surpass the time during which a political party is in power. For the realization of long-term e-Government programs, changes of the power structure can have a negative impact on current developments. To ensure continuity, act independently of interdepartmental power plays, and voice the need for legislative action, those representing e-Government should be independent of political agendas and electoral cycles.

To support complex decision processes and help resolve conflicts, independent advisors belonging to the research community should become an integral part of the decision-making process. Their task is primarily to bring in neutral expertise at the levels of strategy, legislation, technology, and organization. Moreover, they should develop visions and future scenarios that go beyond current structures.

Current e-Government efforts address the typical middle-class family of the Western hemisphere, which is well-educated, computer-literate, nonhandicapped, and equipped with the technical means to take advantage of electronic governmental services. While computer ownership is relatively common in the developed countries of the West and Asia, it is less widespread in the Middle East, and comparatively rare throughout much of Latin America and Africa. For example, while 82% of the Swedish use computers at work, home or anywhere else, at least occasionally, only 9% of the Bangladesh population do so [92.32]. The reasons for this are manifold, including wealth, infrastructure, education, language, age, cultural background, and political conditions, to name but a few. The challenge is to overcome these barriers, which cause the often quoted *digital divide* [92.24]. A particularly promising line of action to overcome the digital divide is to take advantage of the wide distribution and high usability of mobile communication devices, which allow persons who are illiterate but numerate to use electronic government services [92.33]. Other promising initiatives are underway in different parts of the world (see, for example, the case studies provided by the World Bank [92.34]), often promoted by transnational institutions such as the United Nations (UN) or the World Bank. As promising as these examples are, systematic and comparative analysis of the effects of such programs and of the transferability of the applied approach is still needed.

92.4.2 Engineering Challenges

In order to secure continuous support and funding for complex e-Government projects, it is important to produce visible results and tangible benefits early on. This can be achieved by breaking up complex projects into smaller tasks, focusing on *quick wins*. The concept of a quick win refers to a change management strategy which aims to realize projects that have the potential to yield improvements within a short time. Quick-win projects can thus help to build acceptance for further innovation. The key in this endeavor is the business process to be supported by IT. Besides serving as the basis for deriving functional and nonfunctional requirements for e-Government solutions, it supplies the framework for establishing an evolution plan for incremental development.

Gradually increasing the complexity of e-Government solutions has several advantages: firstly, implementing G2B processes which span an entire end-to-end process chain requires substantial financial investment; secondly, by selecting those process steps for which IT solutions can be provided that do not make heavy requirements on users' IT skills nor on their technological equipment, chances are good that users will accept the new technology; thirdly, through incremental development, lessons learned while deploying new technologies can be fed back into development and provide beneficial input to more comprehensive solutions. The challenges here are to identify the right starting point and plan for the right increments.

In the SOA world, this issue is also discussed under the concept of *focus holistically, act locally*. According to this paradigm, it is essential to identify projects that are small enough to avoid failure, but significant enough to attract attention from decision-makers. The software engineering discipline of requirements engineering with its methods for prioritizing requirements can provide guidance here [92.35]. However, an open issue is to (a) establish public-sector-specific prioritization criteria, (b) provide a comprehensive framework for applying them to individual process steps or to a combination of process steps, and (c) provide empirical validation for the criteria.

Besides the question of how to arrive at a prioritization of process steps and at politically and technologically valid roadmaps for solution development, another engineering challenge is to determine the level of component granularity, which allows one to maximize reuse potential. While one of the foremost concerns of the SOA approach is to maximize reuse of components, most public-sector experiences have been in small-scale project contexts; little knowledge exists concerning SOA design on a large scale, spanning different organizational units. In particular, no empirically validated findings with regard to the right level of component granularity are available for the public sector. Future research is needed here, looking at a variety of G2B processes, and analyzing them with regard to the optimal level of reusability.

The SOA approach depends on technical interoperability on one hand, and on semantic interoperability, on the other. The latter is key to the reuse of components across organizational units: there needs to be a shared terminology for exchanging information and a standardized way of interpreting it [92.36]. The challenge here is to define and agree on data exchange standards and underlying ontologies that allow for a uniform interpretation. The federal government of Germany has responded to this challenge and set up the so-called XöV initiative (meaning *XML for public administration*) responsible for developing extensible markup language (XML)-based technical standards for electronic data exchange. The initiative aims at facilitating the seamless exchange of data between agencies on the federal, state, and municipal level as well as between government agencies and their external clients. So far, XML-based standards have, for example, been developed for data exchange between welfare and employment offices (XSozial), and between registry offices (XMeld) (for an overview of current XöV projects see [92.37]).

Despite such promising initiatives, considerable efforts – both in the research community and on the political level – are still needed to achieve semantic interoperability on national and international levels.

93. Collaborative Analytics for Astrophysics Explorations

Cecilia R. Aragon

Many of today's important scientific breakthroughs are made by large, interdisciplinary collaborations of scientists working in geographically distributed locations, producing and collecting vast and complex datasets. Experimental astrophysics, in particular, has recently become a data-intensive science after many decades of relative data poverty. These large-scale science projects require software tools that support not only insight into complex data but collaborative science discovery. Such projects do not easily lend themselves to fully automated solutions, requiring hybrid human–automation systems that facilitate scientist input at key points throughout the data analysis and scientific discovery process. This chapter presents some of the issues to consider when developing such software tools, and describes Sunfall, a collaborative visual analytics system developed for the Nearby Supernova Factory, an international astrophysics experiment and the largest data volume supernova search currently in operation. Sunfall utilizes novel interactive visualization and analysis techniques to facilitate deeper scientific insight into complex, noisy, high-dimensional, high-volume, time-critical data. The system combines novel image-processing algorithms, statistical analysis, and machine learning with highly interactive visual interfaces to enable collaborative, user-driven scientific exploration of supernova image and spectral data. Sunfall is currently in operation at the Nearby Supernova Factory; it is the first visual analytics system in production use at a major astrophysics project. The chapter concludes with a set of guidelines and lessons learned about developing software to support scientific collaborations.

93.1 Scope

Computational and experimental sciences are producing and collecting ever-larger and complex datasets, often in large-scale, multi-institution projects. The inability to gain insight into complex scientific phenomena using current software tools is a bottleneck facing virtually all endeavors of science. As scientific datasets explode at an exponential rate, present-day systems are struggling to capture, process, store, transfer, and interpret data many orders of magnitude greater than scientists have seen before. Computational challenges are arising in unexpected areas, not just in requirements for processor speed, but in software development, scalability, data transfer, and file management. Additionally, it is not sufficient merely to solve the automation challenges; scientific insight and decision-making require human interaction and smooth collaboration with automated systems. However, there are few guidelines or examples to support the interdisciplinary developers of collaborative scientific analytics systems, which need to integrate tools and techniques from a broad array of computing disciplines with highly sophisticated and rapidly changing domain-specific scientific algorithms, as well as incorporate effective human–computer interaction design for scientists.

Among all the sciences, experimental astrophysics is undergoing extraordinarily rapid growth in observational image data captured, at the precise time that new and tantalizing questions about the nature of the universe have arisen, the answers to which will require study of ever-larger areas of the sky in ever-greater detail. As a result, the nature of astrophysics research itself is changing, and many of the algorithms developed for processing astronomical data, although well established for low-volume data capture, do not scale well to today's high-volume sky surveys and transient searches.

One of the grand challenges in astrophysics today is the effort to comprehend the mysterious *dark energy*, which accounts for three-quarters of the matter/energy budget of the universe. The existence of dark energy may well require the development of new theories of physics and cosmology. Dark energy acts to accelerate the expansion of the universe (as opposed to gravity, which acts to decelerate the expansion). Our current understanding of dark energy comes primarily from the study of supernovae (SNe).

The Nearby Supernova Factory (SNfactory) [93.1] is an international astrophysics experiment designed to discover and measure type Ia supernovae in greater number and detail than has ever been done before. These supernovae are stellar explosions (Fig. 93.1) that have a consistent maximum brightness, allowing them to be used as *standard candles* to measure distances to other galaxies and to trace the rate of expansion of the universe and how dark energy affects the structure of the cosmos.

In order to facilitate the astrophysics search and data analysis process and enable scientific discovery for observational astrophysicists, an interdisciplinary group of computer scientists, software engineers, and astrophysicists developed the Supernova Factory Assembly Line (Sunfall), a collaborative visual analytics system for the Nearby Supernova Factory that has been in production use since 2006 [93.2]. Sunfall incorporates:

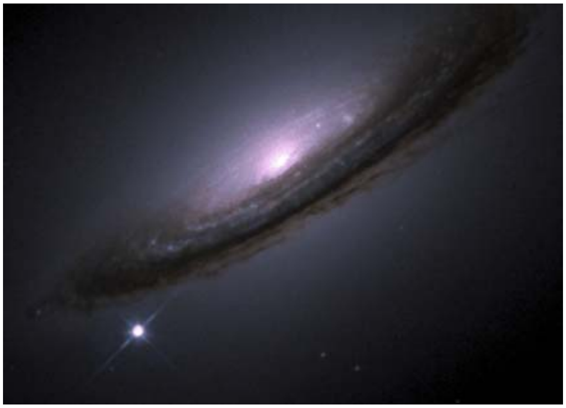

Fig. 93.1 Hubble Space Telescope image of supernova SN1994D in galaxy NGC4526, observed 1994

- Novel astrophysics image-processing algorithms running in parallel on a 300 node cluster
- Machine learning capabilities including boosted decision trees and support vector machines
- A specialized data transfer mechanism that not only manages a large amount of data on a 24/7 basis, but also robustly handles the error-free transfers of a large number of small files
- Highly interactive visual interfaces to enable collaborative, user-driven scientific exploration of supernova image and spectral data.

The remainder of this chapter is structured as follows. Section 93.2 describes the science background for supernova detection and spectral analysis, including the SNfactory project data flow. Section 93.3 contains information on previous work, including systems built for other supernova experiments and other scientific workflow systems. Section 93.4 discusses the Sunfall design approach, and Sect. 93.5 describes the Sunfall architecture in detail, including its four major components: Search, Workflow Status Monitor, Data Forklift, and Supernova Warehouse. Section 93.6 discusses lessons learned and presents our conclusions and their potential impact on the fields of astronomy and cosmology, as many more such large-scale surveys are planned for the future as physicists attempt to unravel the mystery of dark energy.

93.2 Science Background

The discovery of dark energy is primarily due to observations of type Ia supernovae at high redshift (up to $z = 1$, or a lookback time of about 8 billion years) [93.3, 4]. This supernova cosmology technique hinges on the ability to reliably compare luminosities of high-redshift events to those at low redshift, necessitating detailed study of low-redshift events. Large-scale digital sky surveys are now being planned in order to constrain the properties of dark energy. These studies typically involve high-volume, time-constrained processing of wide-field charge-coupled device (CCD) images, in order to detect type Ia SNe and capture detailed images and spectra on multiple nights over their lifespans.

A stellar explosion resulting in a type Ia SN will occur on average only once or twice per millennium in a typical galaxy of 400 billion stars, and then will remain visible for only a few weeks to a few months. Additionally, the maximum scientific benefit is obtained if the supernova is discovered as early as possible before it attains peak brightness. To further add to the challenge, the imaging data from which SNe must be detected are extremely noisy, corrupted with spurious objects such as cosmic rays, satellite tracks, asteroids, and CCD artifacts such as diffraction spikes, saturated pixels, and ghosts.

The SNfactory was designed to accumulate the largest homogeneously calibrated spectrophotometric (containing both images and spectra) dataset ever studied of type Ia SNe in the *nearby* redshift range ($0.03 < z < 0.08$, or about 0.4–1.1 billion light years distant) [93.1]. On a typical night, 50–80 GB of data (approximately 30 000 images containing 600 000 potential supernovae) are received by SNfactory image-processing software. These data are processed overnight; the best candidates are selected each morning by humans for further follow-up measurements. Likely candidate supernovae are sent to a dedicated custom-built spectrograph for follow-up imaging and spectrography. The resulting spectra typically each contain 2000–3000 data points of flux as a function of wavelength. The SNfactory database will be released to astronomers worldwide and become a definitive resource for measurements of dark energy. This program is the largest data volume supernova search currently in operation.

The SNfactory obtains wide-field imaging data from the Near-Earth Asteroid Tracking Program (NEAT) [93.5] using the 112 CCD QUEST II camera of the Mt. Palomar Oschin 1.2 m telescope [93.6], covering 8.5 square degrees per exposure. (For comparison, the full moon covers 0.2 square degrees.)

Images are transferred from Mt. Palomar via the High-Performance Wireless Research and Education Network (HPWREN) to the High-Performance Storage System (HPSS) at the National Energy Research Scientific Computing Center (NERSC) in Oakland, California. Each morning, SNfactory search software running on NERSC's 300 node computing cluster, the Parallel Distributed Systems Facility (PDSF), matches images of the same area of the sky, processes them to remove noise and CCD artifacts, then performs an image subtraction from previously observed reference images on each set of matched images (Fig. 93.2) [93.7–10].

Supernova candidates are identified from among the over 600 000 objects processed per night by a set of image features including object shape (roundness and contour irregularity computed from Fourier contour descriptors) [93.7, 11], position, distance from nearest object, and motion. These features are used as input to machine learning algorithms that select candidates to be sent to humans for scanning and vetting [93.8, 9]. Promising SN candidates that pass the human scanning and vetting procedure are sent for confirmation and spectrophotometric follow-up by the Supernova Integral

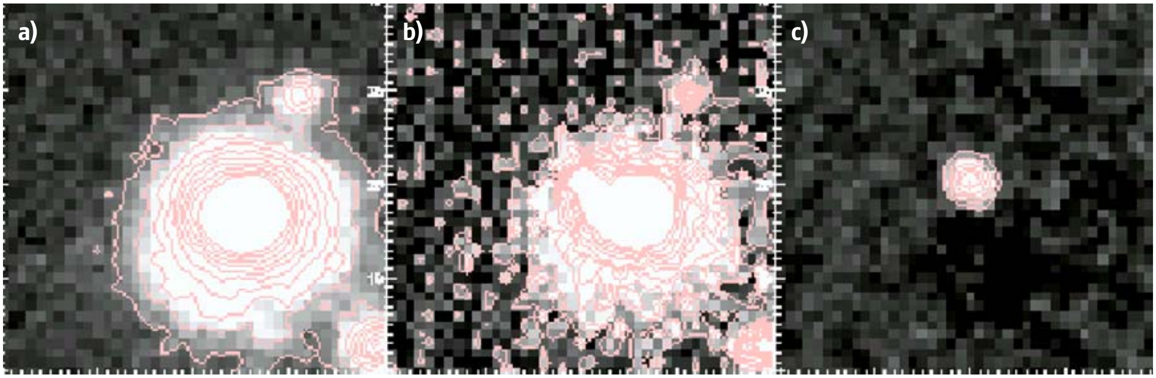

Fig. 93.2a–c Example supernova images. **(a)** Reference image of galaxy, **(b)** new image of galaxy plus new bright spot, **(c)** subtracted image reveals new supernova

Field Spectrograph (SNIFS) [93.12] on the University of Hawaii 2.2 m telescope on Mauna Kea, Hawaii.

Candidates are imaged through a 15 × 15 microlens array on SNIFS and the spectral data are saved to a database in France. The SNIFS observing process is challenging. The telescope is operated remotely, via a text-based legacy control system. Astronomers must be able to analyze and evaluate a large amount of data and make cognitively demanding calculations under time pressure (in some cases in as little as 45 s), while at the same time being fully aware of changing weather conditions, the approach of daylight, and other safety issues. They must focus on individually demanding and precise tasks while maintaining an overall understanding of a large amount of dynamic data affecting the telescope's operation and safety.

Understanding type Ia SNe through their spectra is important because it places constraints on their presupernova evolution and the immediate stellar environment of the event, and provides clues that can expose correlations between peak brightness and the physics of the explosion. With a better understanding of the physics of type Ia SNe through their spectra, it is believed that their utility as standardized candles for cosmological distance measurements can be refined for their use in future precision cosmology experiments such as the Joint Dark Energy Mission (JDEM) [93.13].

93.3 Previous Work

We discuss related work in the areas of astronomical applications, specifically software developed for large-scale supernova searches, and more generally including astronomical calculations and visualizations, and visual analytics systems developed for cognitively loaded or time-pressured users. We also briefly touch on scientific analytics and situation awareness research, as the development of situation awareness at the telescope during observation is critical for astrophysics experiment success.

Since the discovery of dark energy via studies of type Ia supernovae nearly a decade ago [93.3, 4], astrophysicists have developed several large-scale supernova searches to collect as much data as possible on these rare events. These searches typically rely on custom image subtraction software containing highly complex, hand-tuned heuristics and *cuts* to extract supernova candidates. They are often plagued by large numbers of false positives, which must then be screened out by humans in a labor-intensive process. For example, the 2005 Sloan Digital Sky Survey II (SDSS) supernova program generated approximately 4000 objects per night which needed to be visually checked by humans for verification [93.14]. The Equation of State: Supernovae Trace Cosmic Expansion (ESSENCE) and Supernova Legacy Survey (SNLS) supernova searches both resulted in 100–200 objects to scan per night with a significantly smaller input data load than the SNfactory [93.15]. Techniques used in these surveys will not scale to future, much larger data sets.

In 2005, the SNfactory pioneered the use of machine learning algorithms to replace *cuts* for supernova object detection [93.9], and since then, such techniques have been utilized by other supernova searches, including SDSS and SNLS [93.14, 15]. The SDSS *autoscanner* uses a combination of heuristics and a naive Bayes classifier to filter out non-SN objects, but they do not provide a comparison of the efficacy of any other types of machine learning algorithms for supernova search. SNLS uses multinight data and an artificial neural net to screen candidates; however, their techniques are not applicable to large-scale, rapid transient alert pipelines.

After supernova data have been collected, they are typically stored in a database accessible via a web-based interface. These websites display information in tabular form, listing the supernova coordinates and providing links to images. They are designed to provide all the necessary information for astronomers to observe supernovae with their own telescopes. Examples are the SNLS and SDSS web sites [93.16, 17]. In [93.14], *Sako* et al. describe the SDSS software tools for supernova search and follow-up. They include sets of scripts that perform functions similar to parts of Sunfall, but require human intervention at numerous stages during the supernova search and follow-up process. None of these groups has built a complete scientific analytics system that enables human–automation collaboration and encompasses the entire data search, analysis, and scientific discovery process.

The astronomical calculations in the Sky visualization used in Sunfall Data Taking are derived from SkyCalc, originally written by *Thorstensen* [93.18, 19]. Previously, astronomers would run SkyCalc from the command line at the telescope, inputting their observatory parameters, observing date, and target lists. This would provide times of sun and moon rise/set and hourly tables of the elevations of each target. The astronomer would then try to collate this information, but would have to re-input many parameters to examine a slightly different *what–if* scenario. Visual wrappers to SkyCalc have been developed before, including *Thorstensen*'s *SkyCalc GUI* and *SkyCalcDisp* [93.18, 19]; however, the former is simply a graphical version of the command-line interface and the latter contains a three-dimensional projection of object positions that does not facilitate prediction of target motion. On the other hand, the Sky visualization in Sunfall Data Taking was designed specifically to help the astronomer balance the above-described constraints in a visually intuitive way – often during a nighttime observing session – at the click of a button.

The Sky differs from other astronomy visualization programs in that many of them are after-the-fact image-processing programs, designed to enhance faint or low-contrast image data, rather than to provide an operational simplification to aid in time-constrained observational decisions [93.20–22]. Astronomers frequently use tools such as SAOImage ds9 (Smithsonian Astrophysical Observatory Image ds9) [93.23] for detailed viewing of their images, or Image Reduction and Analysis Facility (IRAF) [93.24] for spectral visualization. However, neither of these is integrated into an observing package as is Sunfall data taking.

In the field of scientific visualization for astronomy, software such as *Li* et al.'s scalable World-In-Miniature (WIM) [93.25] focuses on the ability to browse a large-scale three-dimensional model of the universe. However, this technique is not designed for use under time pressure.

There has been much recent work in the development of systems designed for first responders and other cognitively loaded users, including several systems to visualize time-varying data [93.26–29], noting the constraints of updating time-critical visual information on a low-resolution device. Other efforts to develop mobile systems for emergency response include the Measured Response Project of the Purdue Synthetic Environment for Analysis and Simulation [93.30].

Related efforts involve approaches to visualizing time-varying geographic data, such as [93.31–33], and *Tesone* and *Goodall* have developed a visual analytics technique, *smart aggregation*, specifically to aid with situation awareness [93.34]. There is a large body of literature on situation awareness in general, and a full description of such literature is beyond the scope of this chapter. The book by *Endsley* and *Garland* [93.35] provides an excellent survey of the work in this area.

93.4 Sunfall Design Process

In order to design an effective collaborative visual analytics system for the SNfactory, we first conducted, in mid-2005, an extensive, 2 month evaluation of the existing SNfactory procedures and environment. Data sources used for evaluation included individual interviews, observation of team members performing typical project tasks, review of existing source code, literature reviews, examination of other supernova search projects, and consultation with physicists and computer scientists with relevant experience building similar scientific software systems.

We conducted over 100 h of interviews with Lawrence Berkeley National Laboratory (LBNL) scientists, postdoctoral researchers, and students, and SNfactory collaboration members outside LBNL. This included 19 current and former team and collaboration members, and 12 scientists with relevant experience outside the SNfactory collaboration. We also performed a detailed software review of over 150 000 lines of SNfactory legacy code in C++, Interactive Data Language (IDL), Perl, and shell scripts.

We established the following requirements for the Sunfall software framework: It must encompass the entire scientific data capture, processing, storage, and analysis process, enable collaborative, time-critical scientific discovery, and incorporate SNfactory legacy code (custom astronomical image-processing algorithms). It must reduce the number of false positives sent to humans and improve the quality of the subtraction image processing. It must automate repetitive data transfers and other manual tasks to leverage domain experts' unique processing and image-recognition skills to the maximum extent.

The Sunfall user interface was designed and implemented using participatory and iterative design techniques; for example, interactive prototypes were used to evaluate areas where existing interfaces did not support scientists' workflow. Scientists' feedback sometimes led to major redesigns of the interface. The system was implemented from the beginning with this possibility in mind, so that changes were easily made and accepted as an appropriate part of the development process [93.36]. Sunfall has been in operation at the SNfactory since 2006.

93.5 Sunfall Architecture and Components

Sunfall consists of four major components: Search, Workflow Status Monitor, Data Forklift, and Supernova Warehouse (Fig. 93.3). This section will describe each component's structure in detail.

The Search component handles image processing and subtraction, and includes machine learning algorithms and novel Fourier contour descriptor algorithms to reduce the number of false-positive SN candidates. The Workflow Status Monitor is a web-based dashboard that facilitates collaboration and improves project scientists' situational awareness of the data flow by displaying all relevant (search pipeline) status data on a single site.

The Data Forklift is a middleware mechanism consisting of a coordinator and a suite of services to automate astronomical data transfers in a secure, reliable, extensible, and fault-tolerant manner. The Data Forklift also provides the middleware for the other three components, transferring data between heterogeneous systems, databases, and formats securely and reliably.

The Supernova Warehouse (SNwarehouse) is a comprehensive supernova data management, workflow visualization, and collaborative scientific analysis tool. The SNwarehouse contains a PostgreSQL database, Forklift middleware, and a graphical user interface implemented in Java.

93.5.1 Search

The supernova search component of Sunfall is an example of analytic discourse, defined by *Thomas* and *Cook* in *Illuminating the Path* [93.37] as "the interactive, computer-mediated process of applying human judgment to assess an issue", applied to the realm of astrophysics. Sunfall search has increased efficiency of supernova detection and enabled more effective human intervention by reducing the number of false-positive candidates by nearly an order of magnitude [93.8, 9] and, through the use of intelligent interfaces, by increasing human efficiency in evaluating candidates by a factor of four [93.2, 36].

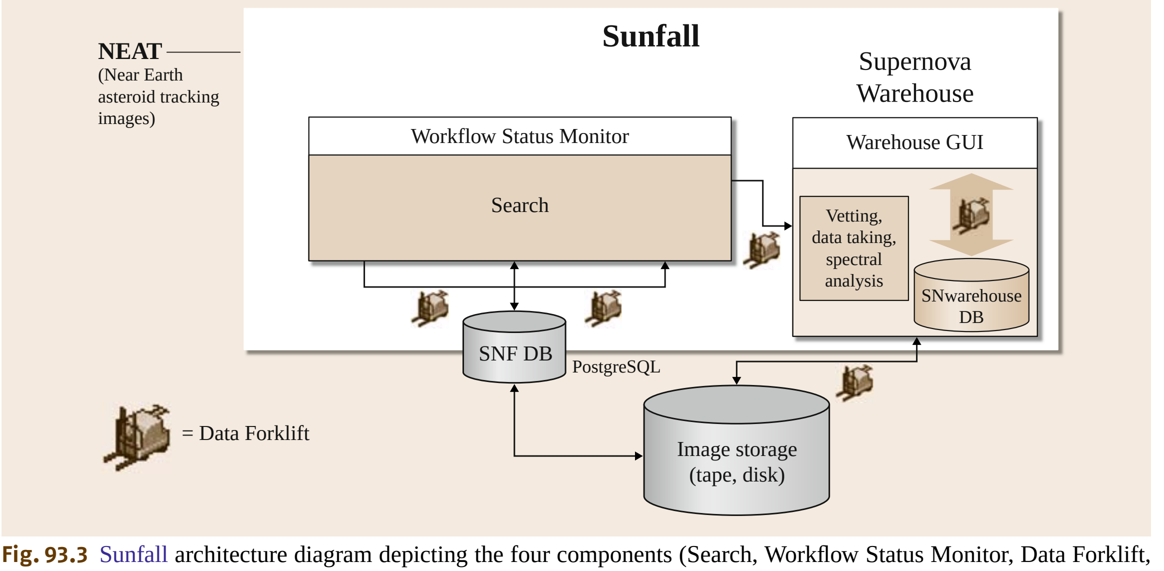

Fig. 93.3 Sunfall architecture diagram depicting the four components (Search, Workflow Status Monitor, Data Forklift, and Supernova Warehouse) and data flow between the components

The legacy search software computed 19 photometric and geometric features on each of over 600 000 SN candidate subimages per night and applied threshold *cuts* to each of these features. Subimages that satisfied all thresholds (1094 on a typical night in October 2005, before the new software was put into production) were sent to human scanners who selected potential SN candidates for follow-up study. The majority of subimages that passed the thresholds were false positives that humans had to manually reject. These manually tuned thresholds were brittle and often resulted in both missed SNe and too many false positives for human scanners to evaluate daily. The process of scanning on the order of 1000 subimages took 6–8 people several hours per day.

We first developed a set of new features for improved image detection, including the use of a very efficient ($O(k)$, where k is the pixel diameter of a supernova candidate) Fourier contour analysis algorithm for determining the shape of an object, described in more detail in the section on fast contour descriptor algorithm for supernova image classification [93.7].

Machine learning algorithms, including support vector machines and boosted trees, were evaluated for incorporation into the search software. By replacing simple threshold *cuts* on the image features with classifiers of the high-dimensional data in the feature space, we reduced the number of false positives by a factor of ten while increasing our rate of supernova detection. We applied several different classification algorithms, including boosted trees, random forests, support vector machines, and combinations of the above. All classifiers provided significantly better performance over

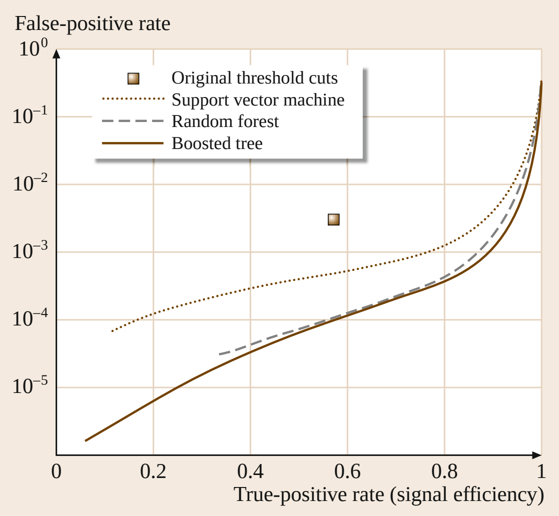

Fig. 93.4 Comparison of boosted trees (*solid line*), random forest (*dashed line*), and support vector machines (*dotted line*) for false-positive identification fraction versus true-positive identification fraction. The *square* shows the performance of the original threshold cuts. The *lower right corner* of the plot represents ideal performance (after [93.8])

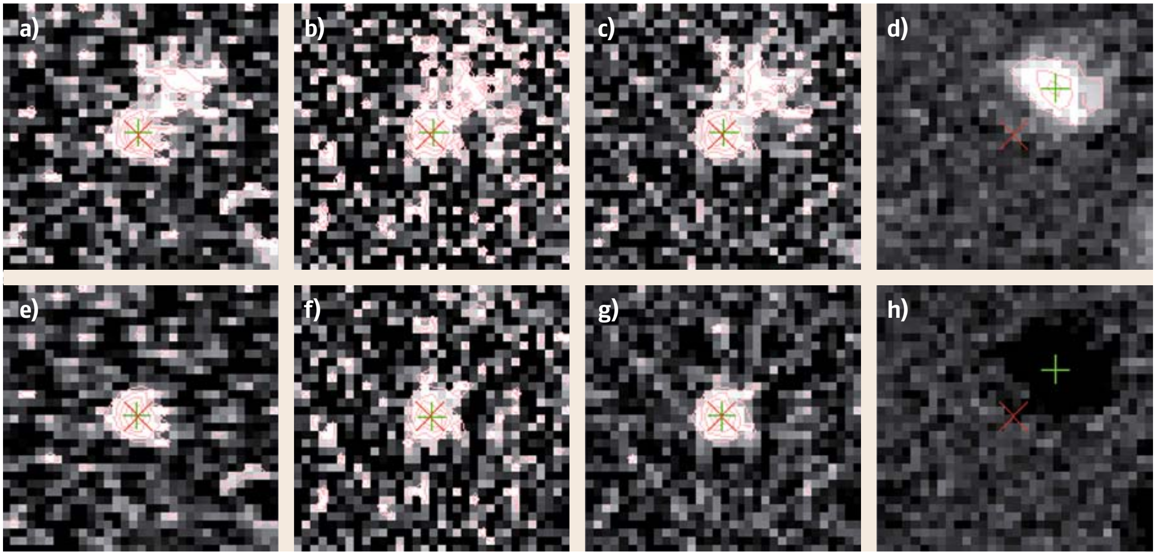

Fig. 93.5a–h Visual scanning interface. *Top row*: three new images **(a–c)**, **(d)** reference image. *Bottom row*: three subtractions **(e–g)**, **(h)** negative subtraction

the conventional threshold cuts. Boosted trees produced the best classification performance overall [93.8] (Fig. 93.4) and significantly decreased scientists' workload by reducing the number of false positives by an order of magnitude (from 1094 to 113 on typical nights in 2005 and 2006). This resulted in labor savings of nearly 90%, where the process of scanning now takes one person a couple of hours each day [93.2, 9]. Additionally, system tests determined that the new algorithms had a true-positive ratio equal to or better than the original algorithm (in other words, they did not miss any more actual supernovae). The data are depicted in Fig. 93.4.

Currently, of the approximately 100 visually scanned subimages per night, about 10–30 are flagged as containing potential supernova candidates. These candidates (about 0.001–0.01% of the objects originally imaged) are sent to the SNIFS spectrograph for spectrophotometric screening and follow-up. Typically two to five of the objects examined by SNIFS will finally be determined to be supernovae, of which (on average) about one per night is the sought-after type Ia supernova. Thus, of the objects originally imaged, somewhere near 0.0002% prove to be type Ia supernovae.

For confirmation and selection of promising supernova candidates, the scanners use a visual interface to view and analyze the candidates (Figs. 93.5 and 93.6). This visual scanning interface was redesigned to increase interactivity and allow humans to focus exclusively on the imagery itself. Previously, scientists spent much of their time cutting and pasting long filenames, pausing the scanning process to look up data on several different external web sites, and waiting for image data to be retrieved from tape storage. Formerly, this process took 2 min per candidate on average; with this interface and other Sunfall tools, a decision could be made within 30 s.

By applying intelligent algorithms to the search data, and by developing intelligent visual interfaces to view the data, we were able to leverage the unique human abilities that enable the final detection of true supernova candidates, and not only minimize the number of false positives, but also increase the efficiency of the spectroscopic follow-up. Techniques such as these are critical for successful human–automation collaboration in scientific experiments. As an example of an algorithm we developed to maximize the effectiveness of human visual pattern-recognition ability by screening out bad supernova candidates before they are presented to users, we now describe our fast contour descriptor algorithm in more detail.

A Fast Contour Descriptor Algorithm for Supernova Image Classification

Fourier descriptors are an established method for parameterizing the outer contour of an object by decomposing it in terms of complex exponential func-

tions [93.11]. However, Fourier-transform-based methods were initially considered infeasible, due to their computational complexity, for the high-throughput requirements of the Supernova Factory. We devised an extremely fast contour descriptor implementation that meets the processing budget of the application. Noting that the lowest-order descriptors (F_1 and F_{-1}) convey the circular or elliptical aspect of the contour, our features are based on those two terms and the total variance or power in the contour. The features are thus equipped to detect eccentric or irregular objects, classes to which the poor candidates generally belong.

Our fast contour descriptor algorithm was applied to 600 000 candidate objects in 50–80 GB of supernova image data per night. Our shape-detection algorithm reduced the number of false positives generated by the supernova search pipeline by 41% while producing no measurable impact on running time. Because the number of Fourier terms to be calculated is fixed and small, the algorithm runs in linear time, rather than the $O(n \log n)$ time of a fast Fourier transform (FFT). Constraints on object size allow further optimizations so that the total cost of producing the required contour descriptors is about $4n$ addition/subtraction operations, where n is the length of the contour.

Because transform-based image analysis methods are often avoided in high-throughput applications due to their computational cost, it is important to distinguish the contour Fourier descriptor from other Fourier-based methods. For a two-dimensional image of diameter D pixels, the processing time for a Fourier transform of the image can scale as severely as D^4. In fortunate cases where the Cooley–Tukey FFT [93.11, 38, 39] can be used, the processing still scales as $D^2 \log(D^2)$. The contour Fourier descriptor operates not on the object image but on its outer contour, which is essentially a one-dimensional (albeit complex-valued) sequence, of length proportional to object diameter D. Since we calculate a fixed number of terms rather than requiring a full discrete Fourier transform (DFT), the calculation time is actually proportional to D.

Algorithm Overview. We compute two new features (or *scores*) on each subimage containing an object, and add them to the set of features already calculated in the supernova search pipeline. These two features are: $R1$, which measures the *roundness* or eccentricity of the candidate object, and $R2$, which measures the amount of irregularity in the object contour.

Our approach inserts the following steps into the processing pipeline for candidate supernova objects:

1. Find the outer contour of the object and store it as a sequence of (x, y) points.
2. Calculate the lowest Fourier descriptor terms F_1 and F_{-1} on the contour point sequence.
3. Form two roundness-related features: $R1$ measures the eccentricity of the object (0 is a circle, 1.0 is a line, and intermediate values are ellipses); $R2$ measures the amount of irregularity in the object contour

$$R1 = \frac{\|F_1\|^2}{\|F_{-1}\|^2} ,$$

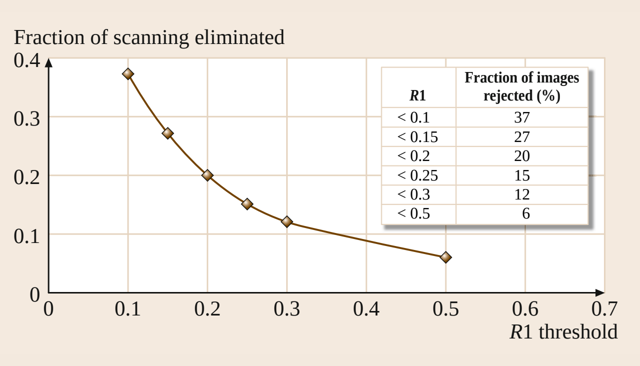
$$R2 = \frac{\sum\limits_{|k|>1} \|F_k\|^2}{\sum\limits_{k \neq 0} \|F_k\|^2} .$$

The features $R1$ and $R2$ are added to the list of thresholds or *cuts* applied to image objects, so that objects with too high $R1$ or too high $R2$ are rejected as supernova candidates, and are not sent for human scanning.

Algorithm Results. For testing, the fast contour descriptor algorithm was implemented and incorporated into the existing supernova search pipeline software. The new scores $R1$ and $R2$ were added to the existing image feature set, without yet setting thresholds, but with diagnostic output to permit analysis of the distribution of scores. First, we examined the scores within the class of good candidates, using a validation set of 90 supernovae. For the first roundness feature, all of the supernovae in the validation set yielded $R1 \leq 0.08$ (and frequently much closer to zero). For the second feature, nearly all (89 of 90) gave $R2 < 0.1$.

A second evaluation was performed on a much larger data set representing both classes (good and bad

Table 93.1 Graph and table of image rejection rate versus $R1$ threshold



R1	Fraction of images rejected (%)
< 0.1	37
< 0.15	27
< 0.2	20
< 0.25	15
< 0.3	12
< 0.5	6

candidates), to determine appropriate threshold values for $R1$ and $R2$. The goal was to reduce the scanning load (remove the bad candidates) as far as possible without sacrificing any good candidates (possible supernovae) at all. The algorithm was run on a test set of approximately 35 000 subtracted images, of which 1094 would

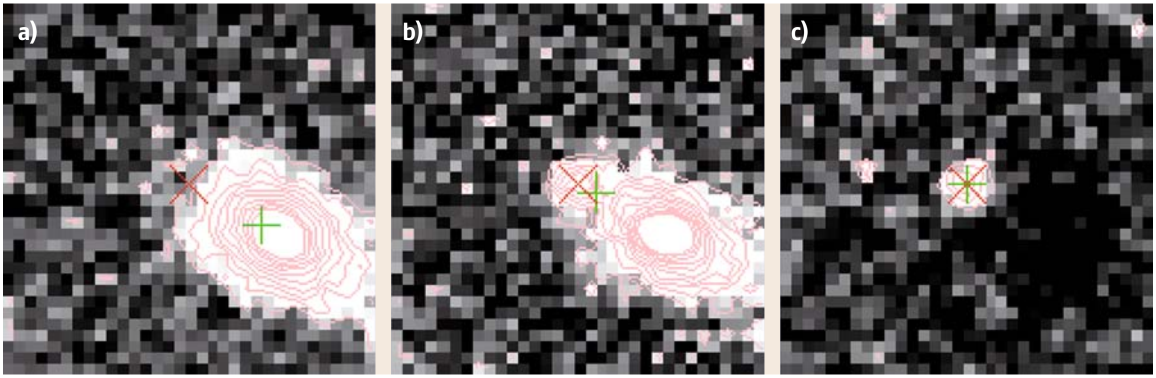


Fig. 93.7a–c Supernova found in November 2006 by the Nearby Supernova Factory: SNF20061117-000. **(a)** Reference image of galaxy, **(b)** new image of galaxy plus bright spot, **(c)** subtraction revealing new supernova

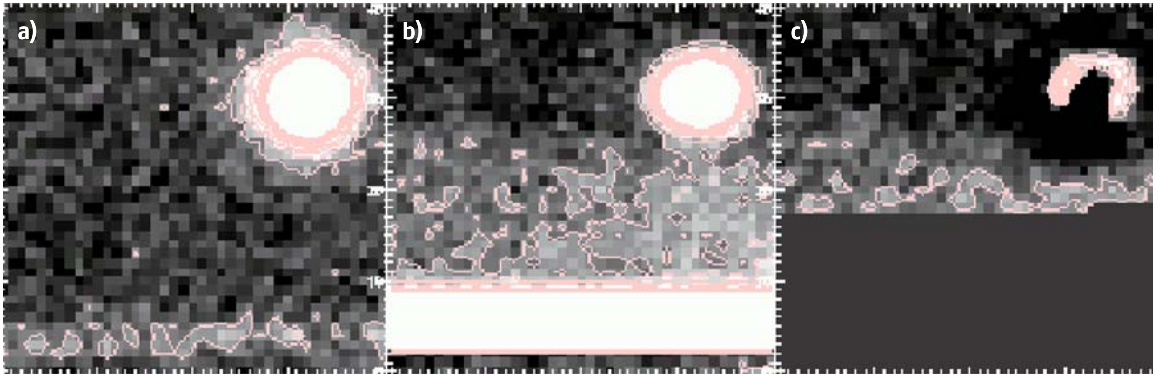

Fig. 93.8a–c Example of a bad subtraction. **(a)** Reference image, **(b)** new image, **(c)** subtraction (the images were misaligned, leaving the subtraction with a meniscus-shaped object). This object is screened out by $R1$

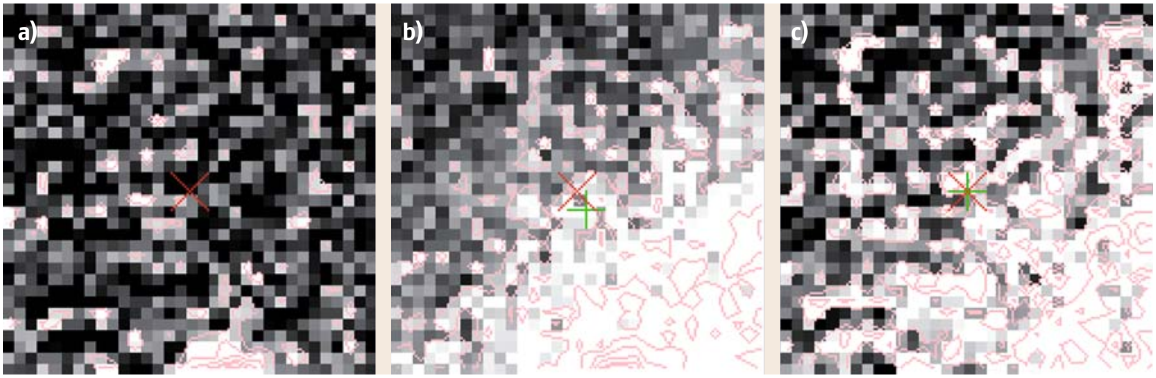

Fig. 93.9a–c Example of a bad subtraction. **(a)** Reference image of empty space, **(b)** new image with edge of bright object present, **(c)** subtraction with an object that is not round and has an irregular contour. This object is screened out by $R2$

have been sent to a human for evaluation under the old parameters. The fraction of those 1094 which would be rejected (i. e., not sent for human scanning) under various settings of $R1$ was calculated; the results are shown in Table 93.1.

A similar test was then performed for $R2$. On the basis of the combined results, thresholds for $R1$ and $R2$ were chosen at 0.1 and 0.15, respectively. At those settings, the number of images passing the thresholds and sent to human scanners decreased to 647 (versus 1094 under the old criteria). This is a scanning load reduction of 41%, representing a saving of ≈ 6 h of manual scanning labor each day.

Figures 93.7–93.9 show examples of subimages viewed during this process. Each figure depicts a triplet of reference/new/subtraction images (the reference image is from before the supernova explosion, the new image is the current one including the supernova, and the subtraction depicts the new bright spot alone). All of these subimages were *passed* by the search software before our new roundness features were added. The first figure (Fig. 93.7) depicts a good candidate (note the compact circular form), but the next two figures (Figs 93.8 and 93.9) display bad subtractions which should have been culled out. After our algorithm had been implemented (features $R1$ and $R2$ added to the threshold criteria), Fig. 93.8 failed the $R1$ cut and would not have been passed for human scanning. Figure 93.9 failed the $R2$ cut and likewise would not have been passed.

93.5.2 Workflow Status Monitor

The Workflow Status Monitor is a web-based dashboard application, designed to improve project scientists' situational awareness of the data flow by synthesizing diverse information flows from various systems and displaying critical workflow status data on a single site (Fig. 93.10).

The supernova search software is highly parallelized as 30 000 images are queued for processing in a multistage pipeline that runs on NERSC's 300 node computing cluster, the Parallel Distributed Systems Facility (PDSF). Nodes frequently go down or jobs fail, and failures must be detected promptly and jobs resubmitted quickly due to the time-critical nature of the search. Detection of such failures was challenging and time-consuming before the deployment of the Workflow Status Monitor. The monitor displays graphs and visual displays of job completion times on PDSF, job queues, PDSF node uptimes, and disk vault loads. The interface was prototyped, evaluated for efficacy by project scientists, and implemented via Hypertext Preprocessor (PHP) on a website hosted on an SNfactory server running SuSE Linux.

The dashboard also displays date and time information at project locations, in several formats relevant to astronomers. Computer scientists developing a status monitor for the Mars exploration rovers [93.40] demonstrated that apparently minor features, such as a clock that displayed the time on Mars and at various project locations on Earth, yielded tremendous improvements in scientists' situational awareness and may very well have prevented critical errors. Additional information displayed includes telescope scheduling, supernova candidates found, and current operational status of telescopes, spectrographs, and cameras used in processing SNfactory data.

93.5.3 Data Forklift

Each night, over 50 GB of heterogeneous, distributed supernova data arrive at the SNfactory and need to be processed, managed, analyzed, queried, and displayed – all within a time period of 24 h or less (ideally 12 h). The data are distributed over wide geographic distances; some of it is hosted on systems outside the SNfactory's control, and some on unreliable systems with frequent downtime.

To solve these data management problems, we designed and implemented the Sunfall Data Forklift, a suite of services for automated data retrieval, storage, movement, querying, and staging for display. The Data Forklift consists of a coordinator and a set of individual services, each customized for its particular task, but having key attributes in common.

The Data Forklift supports *different place*, *asynchronous* collaborative scientific work by facilitating data and information transfer amongst a geographically separated team. Due to the time-critical nature of the data collection (telescopes must be operated at night and are located in different time zones), tasks must take place at distinct, specified times.

All Data Forklift services share the following properties:

- The mechanism resides at a central location (an SNfactory server), but processes data remotely from widely separate geographic locations, including making connections to external machines not under the SNfactory's control.

Fig. 93.10 Sunfall Workflow Status Monitor. This web-based dashboard presents a single-page overview of many relevant information flows from multiple systems and, according to project scientists, increases operator efficiency significantly

- All data transfers are secure, utilizing encrypted channels and authentication.
- The Forklift services and coordinator are reliable and self-restarting. The Forklift coordinator restarts itself if its process dies or if the server is rebooted.
- The mechanism is fault tolerant; services detect unreliable connections and recover from errors in data transfer. Partially transferred files are detected and retransferred, and the process restarts the transfer at the point of failure.
- The mechanism is extensible (new tasks can easily be added). The Forklift coordinator was designed so that new services can easily be added to a central table.
- The Data Forklift enables data retrieval from external sources. Many astronomical databases are web-based, and designed for interactive rather than automated retrieval. Forklift services handle such interactions in a fault-tolerant manner. SNfactory spectral data are stored at a central processing database in France, and must be retrieved according to external requirements.
- User actions can trigger Data Forklift requests. For example, whenever a supernova candidate is

saved to the Supernova Warehouse (SNwarehouse) database, several Forklift services are automatically started, retrieving related image data from tape storage, accessing external web-based asteroid, galaxy, and other astronomical databases, converting image files into display format, and staging data for display.

- Forklift services act as middleware for the SNwarehouse, retrieving data from internal and external databases, performing program logic, and staging data for display by the SNwarehouse GUI.
- The Data Forklift is written in Perl, and runs under SuSE Linux 9.3 on an SNfactory server.

93.5.4 Supernova Warehouse

The SNwarehouse is a comprehensive supernova data management, workflow visualization, and collaborative scientific analysis application. It consists of a PostgreSQL database hosted on a dedicated SNfactory database server running SuSE Linux 9.3, Data Forklift services as middleware, and a graphical user interface (GUI) writ-

ten in Java. SNwarehouse supports collaborative remote asynchronous work in several different ways.

Collaboration members can access the GUI from any networked computer worldwide via a Forklift remote deployment mechanism. Security is provided via password authentication and encrypted communication channels. SNwarehouse furnishes project scientists with a shared workspace that enables easy distribution, analysis, and access of data. Collaboration members can view, modify, and annotate supernova data, add comments, change a candidate's state, and schedule follow-up observations from work, home, while observing at the telescope, or when attending conferences. This access is critical due to the 24/7 nature of SNfactory operations. All transactions are recorded in the SNwarehouse database, and the change history and provenance of the data are permanently stored (records cannot be deleted in order to maintain the change history) and continuously visible to all authenticated users.

SNwarehouse centralizes data from multiple sources and supports task-oriented workflow. Project members perform well-defined tasks, such as vetting, scheduling, and analyzing targets, which collectively accomplish the goal of finding and following type Ia supernovae. Typically, an individual or small group performs a given task, and the results of the task provide inputs for the next task in the workflow, often performed by another set of group members. Thus, the inputs and outputs of any task must be well defined and easily recognizable.

SNwarehouse Overview

SNwarehouse facilitates five major tasks: overview, supernova candidate vetting, observation scheduling (determining the order of observation of targets for a single night), data taking (capturing spectral data at the telescope with SNIFS), and post mortem (spectral data analysis and classification). These are each described in more detail in the sections ahead.

SNwarehouse's interaction design takes the approach of overview, filter, and drill down to details. The main overview page (Fig. 93.11) displays two tightly coupled representations of the list of targets registered in the database. The top visualization plots the targets in the sky; below is a sortable, tabular representation of the same data. From here one can drill down as needed based on the desired task.

Supernova Candidate Vetting

Vetting involves a process of scientific analytic discourse where the scientist must quickly decide, based on limited data, how to allocate scarce and expensive telescope time to the night's supernova candidates. At this point, before spectra are taken, it is often unknown whether a target candidate is a supernova, so the scientist must gather as much relevant data as rapidly as possible to make an informed prediction. This task involves retrieving any available images of the target's location in the sky prior to discovery and querying several external astronomical databases.

Once a target is saved as a candidate supernova, the target name will appear in the SNwarehouse overview table, color-coded in red, indicating that the target is newly discovered. On a rolling basis, a background process checks if previous data products exist on disk. If found, these data products are registered with the database, and an exclamation mark appears next to the target name, a flag signaling newly found images. The combination of these two visual clues allows the scientist to quickly see which targets need evaluation. Once this determination is made, the vetter will then open the details view for the target (Fig. 93.12).

At this stage, the vetter is trying to determine whether this target is potentially a type Ia supernova, based on how consistently the magnitude is rising in comparison with standard type Ia supernovae. The details view helps the vetter make this determination in two ways. First, a visualization of the magnitudes of all target observations against a standard type Ia light curve (Fig. 93.13) allows the vetter to determine quickly if the magnitudes are rising like those of a typical type Ia supernova. In addition, the vetter can compare the discovery image with prior images taken at this particular set of coordinates in the sky (Fig. 93.14).

Observation Scheduling

Prior to follow-up observation at the telescope, a schedule is made based on the vetter's assessments to order and allocate telescope time. In SNwarehouse, the scheduler starts by filtering for only those targets with observation requests. With this list, the scheduler must order and assign exposure times for each target using a variety of techniques. Exposure times are automatically determined using a lookup table based on the phase and redshift of the target. Considering these exposure times, the scheduler must also order the target list according to when the target will be visible in the sky by the telescope. A custom visualization offers insight for this task.

The Sky visualization (Fig. 93.15) depicts the positions of targets in the sky at a given time and ground location. The green lines represent air mass (atmosphere thickness) for target coordinates at the specified time.

plan observations for the remainder of the night. If the target appears within the blue horizon lines, it is visible to the telescope, assuming good weather. The scheduler must note the rise and set times of each target when creating the schedule for the night.

It can be challenging for humans to imagine and visualize the path of astronomical objects over time, as they appear to move along the inside of the hemisphere of the night sky. Further, even an astronomer skilled in the art of visualizing celestial coordinates can have difficulty predicting the paths of several objects in the night sky, accurately estimating which of them will avoid clouds, and calculating when they will reach the optimal position for observing.

The key idea in the Sky visualization is the mapping of the spherical night sky to a two-dimensional rectilinear projection, where astronomical objects' paths over time move linearly from left to right. Although there is some spatial distortion (similar to that of a Mercator projection of the Earth [93.41]), it is much easier for observers to predict the future position of objects moving along a linear path in a plane.

The Sky visualization is used throughout SNwarehouse, and is especially helpful for the spectral data collecting component of SNwarehouse, Data Taking.

Data Taking

During each night of spectral observations with SNIFS at the University of Hawaii 2.2 m telescope, an observer needs to point the telescope at each scheduled target in order. In the event of weather or mechanical problems, a rescheduling decision must be made quickly and efficiently. The Sunfall data-taking interface facilitates this process. Much of the observation procedure is automated, allowing the observer to concentrate on troubleshooting, rescheduling, and determining the success of each target observation (Fig. 93.16). Nevertheless, human input is crucial during the telescope

observing process, as the scientists must evaluate large amounts of dynamic data and make time-critical decisions that cannot be automated, often in as little as 45 s. Participatory design was a natural choice for Sunfall Data Taking, especially given that expert domain knowledge was needed to define the use cases. Scientists were involved in the design process from the start, helping to define the problem space and outlining the necessary functions. The design of the data-taking GUI went through several prototypes prior to release, including low-fidelity paper prototypes and high-fidelity semifunctional prototypes. Each prototype was evaluated by the scientists, who provided feedback on areas where the interface was confusing or too tedious to use (i. e., too many steps to perform a particular task).

Since telescope observation procedures are one of the key elements of SNfactory science, and thus Data Taking is an important component of SNwarehouse, we will discuss this component's design, implementation, and use in the system in greater detail in the next few Subsections.

Telescope Observing Procedures

Each night of spectral observations with SNIFS at the University of Hawaii 2.2 m telescope requires a complex set of procedures involving collaboration among a geographically distributed team, and the operation of legacy software telescope controllers driving one-of-a-kind hardware.

The scientist performing the night's observations is known as the *shifter*. The shifter may be located anywhere in the world, although SNfactory collaboration members attempt to distribute the operational tasks among time zones so as to minimize nighttime work.

Additional members of the team include a telescope operator physically located in the Hilo, Hawaii, operations room, and senior scientist experts who may be physically located on the other side of the Earth from the current shifter. At the end of the shift, another scientist evaluates each night's set of observations using a slightly different view of the same data.

Legacy Software Interface

The telescope interface is complex, involving a number of shell scripts which must be run from the command line at various times. Functions of the interface include data monitoring as well as telescope control. The scripts interface directly with the telescope and spectrograph device drivers. There are several systems that directly control the telescope.

The telescope control system (TCS) user interface was written using *curses*, a Unix terminal control library originally developed in 1977 [93.42]. When TCS was originally written, space was at such a premium on the screen that the developers were forced to use every possible shortcut; for example, the Scottish word *hie* is used to describe the state of one of the mirrors when it is moving between two positions.

There are also two *directors*, which monitor a large amount of information from three CCD cameras, the SNIFS instrument itself, as well as the TCS. These five information streams are piped into two windows, resulting in an extremely rapid flow of information past the eye. The display is filled with blinking and scrolling text, as numeric values are dynamically updated and various internal program status messages rapidly scroll across several text windows (Fig. 93.17). High-priority error messages are printed in red to distinguish them from lower-priority status messages; however, all the flickering and movement on the screen can be distracting, especially since relatively unimportant status messages are continuously scrolling past the window.

To start the night's observing, the shifter must first establish an secure shell (SSH) tunnel to the Mauna Kea summit computer (a Dell Dimension PC running Red Hat Linux), then connect to a virtual network comput-

Fig. 93.17 VNC telescope control window with chat client

ing (VNC) server on the summit machine, opening two local windows to establish the interface. Two other machines at the summit are custom-built, possessing Tyan motherboards that each enable operation of two camera Peripheral Component Interconnect (PCI) interfaces simultaneously. The shifter must also connect to a prearranged chat room where all scientists involved in the observation participate, ask questions, provide advice, and use an informal protocol to transfer positive control of telescope operation.

To a novice user, the telescope interface is dauntingly complex. The learning curve is extremely steep at the beginning of training. The scientists concluded that it was critical to reduce the shifter's decision-making load. They initially decided that the best method of doing this was to create an *autopilot*, an automated instrument control program that would run the entire observing process without human intervention. However, unexpected hardware interactions as well as operational changes ensured that the automated instrument control program could not run autonomously throughout the night. Additionally, it proved impossibly complex to modify the program to reliably compensate for the plethora of unexpected events that could occur during a night's observing; human intervention was consistently required.

Based on this initial experience, it was determined that the shifters needed a decision support system to supplement the automation. Although some level of automation was necessary to reduce drudgery and lighten the shifter's workload, it became clear that a system was needed that combined automation with a visual interface that facilitated human intervention. The scientists instituted various protocol changes, and the data-taking system was designed and implemented by an interdisciplinary team of computer scientists and astrophysicists, alleviating many sources of shifter error. Tasks that the shifters performed with data taking included viewing spectral images, exploring data, keeping a standardized *notebook* on sky and instrument conditions, and decision-making. The intent was to have the shifters allocate their attention to higher-level tasks, in particular: evaluating their rate of performance on the schedule, determining whether or not conditions sufficed to perform lower-priority observations, and assessing data quality.

Data-Taking Components

The data-taking GUI is depicted in Fig. 93.16. This interface runs as a separate window on the summit computer and is intended to augment rather than supplement the existing telescope control interface. Operational constraints during software development precluded a complete redesign of the entire telescope control interface, although incremental improvements were made.

The automated instrument control program was left in place; if nothing goes wrong during the night, it will automatically slew the telescope to each target in turn, start an exposure of the correct length, record the

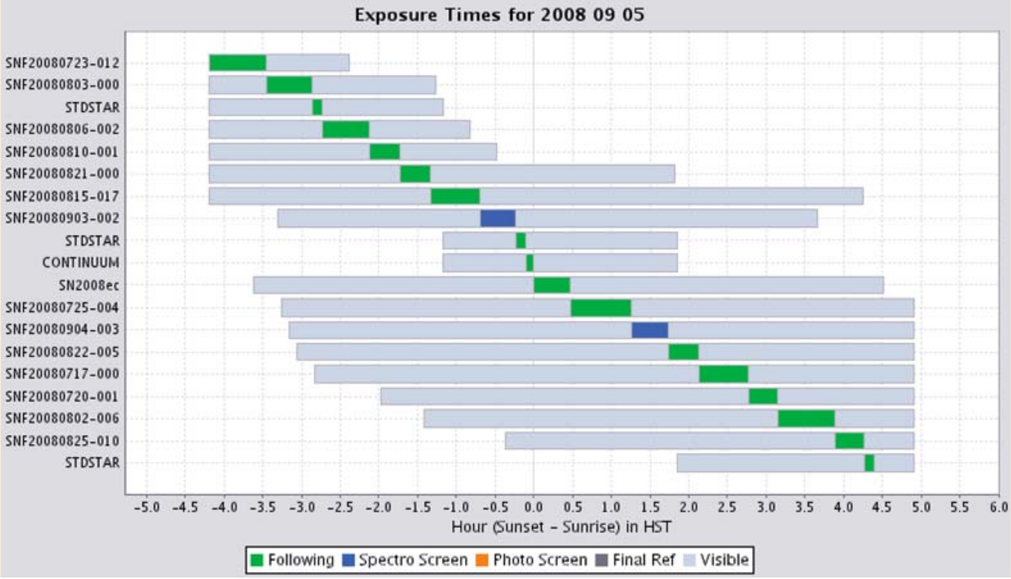

Fig. 93.18 The Visible Time display depicts object visibility and exposure times

data, and move on to the next target. However, in the event of weather or mechanical problems, quick and accurate decision-making is required. Data Taking was designed to support such decisions, with the express goal of improving the shifter's situational awareness. To this end, a number of components were designed to provide supplemental information about critical observing conditions, as well as provide predictive tools to enable the shifter to make scheduling decisions easily and correctly.

Since the shifter is operating the telescope remotely, they may be unaware of deteriorating weather conditions or the approach of sunrise. A software agent running in the chat room broadcasts key astronomical events such as sunrise, and provides information on current telescope operation, including the current exposure or the process of slewing to new coordinates [93.43].

Prior to each night's observation at the telescope, a schedule is made in order to allocate telescope time to each target. In SNwarehouse, the scheduler starts by filtering for only those targets with observation requests. With this list, the scheduler must order and assign exposure times for each target using a variety of techniques. Exposure times are automatically deter-

Fig. 93.19 SNwarehouse details view depicting spectral data observations. The small *postage stamp* images on the *left-hand side* of each observation subwindow indicate the accuracy and signal strength of the received data

mined using a lookup table based on the phase and redshift of the target. To assist the scheduler in planning the night's observations, the Visible Time tool was implemented (Fig. 93.18).

Visible Time Display

The Visible Time plot visually depicts the night's schedule by displaying at a given hour what targets are visible in the sky. In addition, the plot shows the start times and the length of the exposure scheduled for each target. The exposure is color-coded according to the type of observation, a spectrum, a photometric screen, or a final reference. Green bars indicate supernovae that the project is *following*, i. e., an interesting object where a series of spectra have been obtained over time, and more are desired. Blue indicates a spectroscopic screening is desired, because the type of the object has not yet been discovered. A marker on the plot (the zero line above) indicates the current time, which along with the visual representation of the schedule, helps the shifter keep track of events. Feedback from scientists showed that the visibility chart aided in decision-making, easing decisions to cancel an exposure or to insert an extra observation in the schedule.

Post Mortem

Once observation at the telescope is complete, the data products (images and spectra) from the telescope are registered with the database and marked with an exclamation mark in the SNwarehouse overview page. The next task is spectral processing and analysis, known as the *post mortem* process. The scientist performing post mortem filters for targets with new data products that are being followed (highlighted in green and blue, depending on the type of follow-up) and opens up the details view to evaluate the telescope results (Fig. 93.19).

The raw data from the SNIFS spectrograph is complex and requires a significant amount of processing to yield meaning to the scientist. A visual depiction of the accuracy of the telescope aim and signal strength provides more information more quickly than tables of numeric data. The two small images (*postage stamps*) on the left-hand side of each observation subwindow (Fig. 93.16) are a custom visualization designed by scientists to indicate whether the telescope is accurately pointed at the target and whether a good signal was received by the spectrograph.

The data taken by SNIFS consists of two channels, blue and red. A channel produces a spectral decomposition of each sample of a 15 × 15 pixel image of a $6'' \times 6''$ square of the sky. Thus, each channel produces an x by y (position) by λ (wavelength) *datacube*. To make the SNwarehouse postage stamps, the datacube is collapsed (averaged) along the λ-axis, leaving an x by y image. Since this image averages over many wavelengths, it is more accurate than a single wavelength slice, roughly as $(N_{\text{slices}})^{1/2}$, where N_{slices} is the datacube dimension in the wavelength direction. The program that performs

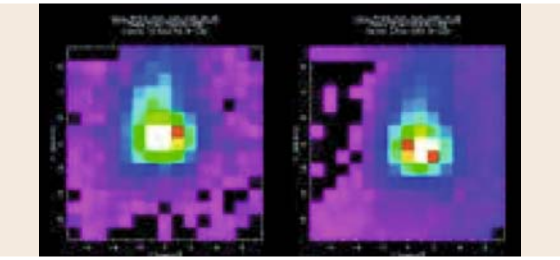

Fig. 93.20 A successful spectral observation. The *bright spot* in the center represents the supernova, and indicates that the target was centered by the spectrograph and the signal was good

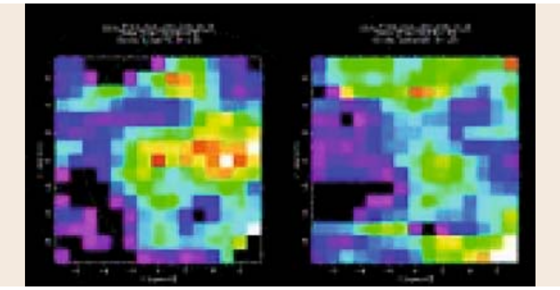

Fig. 93.21 A failed observation. No obvious target appears visible, so no useful spectral data was captured. This could happen due to a telescope pointing mishap, say the dome closed due to a humidity spike

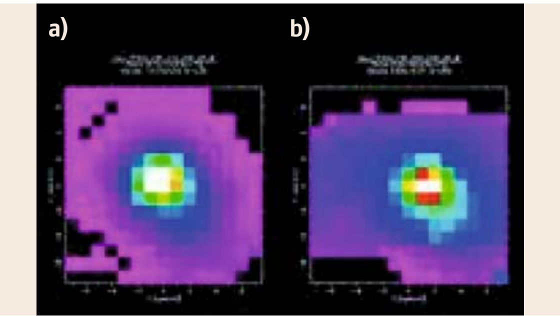

Fig. 93.22a,b A marginal observation. In **(b)** a blue halo surrounds the *bright dot* in the center, indicating that too much noise from the supernova's host galaxy has been picked up, skewing the spectral results

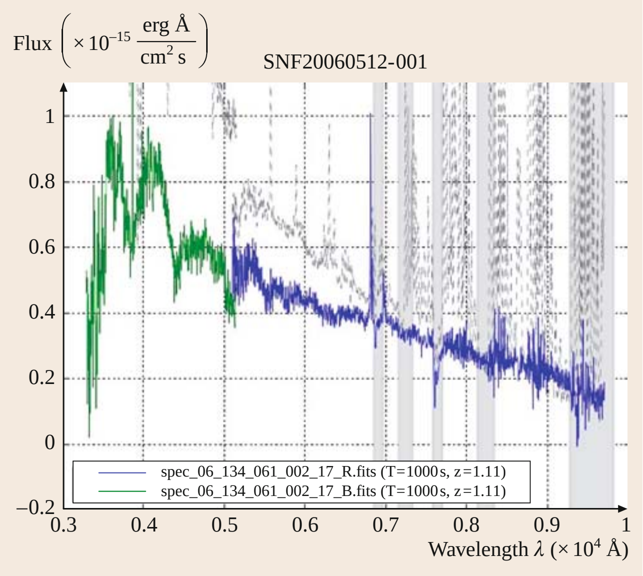

Fig. 93.23 A spectrum from a very early type Ia supernova, 15 days before peak brightness. The *green* and *blue plots* indicate the spectral data. The spiky *grey lines* in the background depict the background sky spectrum. This supernova is just starting to show the features that define it as type Ia ◀

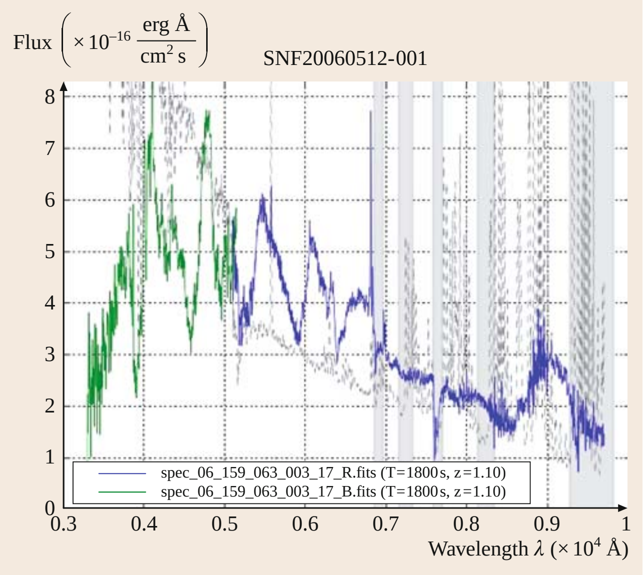

Fig. 93.24 Spectrum of the same type Ia supernova at 10 days after peak brightness. Note the different profile of the spectrum. To a domain expert, each of the peaks and troughs has meaning

this operation is run as part of the real-time SNIFS pipeline that is run after each spectrum is read out.

Color-coding and position indicate the accuracy and signal strength of the received data. If there is a bright dot in the center of both squares, that is a clear indicator of a *good pointing* (Fig. 93.20).

A failed observation contains no clear bright circle in the center of the image Fig. 93.21. A marginal observation may contain a blue halo, indicating that too much background noise from the supernova's host galaxy is present, and that the spectral data may be skewed (Fig. 93.22).

Supernova scientists, like many domain experts, demonstrate strong visual pattern-recognition ability in their field of expertise. They can take a single glance at a picture of a complex spectrum, and instantly determine its type, age in days before or after peak brightness, and whether it exhibits any unusual properties. An early type Ia supernova (captured well before peak brightness) will display a certain pattern in its spectral plot (Fig. 93.23). A later supernova (imaged a few days past peak brightness) will show other characteristic spectral lines and features (Fig. 93.24). The spectral data are displayed in optimal form in order to facilitate domain experts' visual pattern-recognition ability. Spectral data are plotted in green and blue. The spiky grey lines depict the spectrum of the background sky. The broad grey bands represent areas of atmospheric absorption. Due to the complexity of the data (thousands of points of flux versus wavelength for each observation) and the necessity to make rapid, accurate decisions in order to maximize the use of limited, expensive telescope time, visualization provides the most efficient solution to the problem. The scientist can also access the raw numeric data by clicking on any of the images or spectra.

93.6 Conclusions

Sunfall, a collaborative visual analytics system in operation in a large-scale astrophysics project, has demonstrated that such systems can have a positive impact on data-intensive science. In July 2005, at the commencement of the Sunfall project, the SNfactory had discovered no supernovae. As of November 2008, the SNfactory has discovered over 1000 supernovae, of which some 600 are spectroscopically confirmed and nearly 400 of which are the critical type Ia SN so useful for cosmological research. By focusing on improvements in automation, Sunfall has led to more efficient data processing and significant labor savings for project scientists, enabling them to concentrate on physics research, including supernova discovery and analysis, and scientific publications, rather than on repetitive tasks. See Table 93.2 for supernova search data processing improvements, and Table 93.3 for details on labor savings (over five full-time equivalent staff per year) realized by the SNfactory project since the development of Sunfall.

Additionally, the framework architecture, efficient visual interfaces, and algorithms developed for Sunfall may be transferable to future large-scale automated transient alert pipelines such as the Joint Dark Energy Mission (JDEM) [93.13] or the Large Synoptic Survey Telescope (LSST) [93.44].

Sunfall search and the Sunfall status monitor, by incorporating sophisticated image-processing algorithms and machine learning capabilities with a usable, highly interactive visual interface designed to facilitate collaborative decision-making, reduced the number of false-positive supernova candidates by a factor of ten and reduced scientist scanning workload by 90%.

Table 93.2 SNfactory supernova search data rates before and after improvements

	Oct. 2005 (before search improvements)	Oct. 2006 (after search improvements)
Square degrees of sky processed per night	215	725
Processing time	< 24 h	< 24 h
Supernova selection efficiency	60%	75%
Objects scanned by humans per day	1094	113

Table 93.3 SNfactory labor rates in full-time equivalent staff (FTE) by task before and after Sunfall implementation

Tasks	2005 (FTE before Sunfall)	2007 (FTE after Sunfall)
Search	1	0.2
Scanning	3	0.25
Vetting	1	0.15
Scheduling	0.5	Automated
Postmortem	0.5	0.15
Total	6 FTE	0.75 FTE

Sunfall data taking, the visual analytics subsystem for astrophysicists collaboratively operating a large telescope for time-critical supernova observation, demonstrated the effectiveness of a simplifying visualization, projecting three-dimensional data to a rectilinear two-dimensional format, in enabling users to synthesize large amounts of streaming data and make critical decisions under time pressure. This confirms previous studies [93.26, 28, 45] on the value of simplifying visualizations in interfaces designed for cognitively overloaded users. Furthermore, we demonstrated that the cultivation and maintenance of users' situation awareness, a concept first studied in the field of aviation and cockpit management, is crucial in other fields where time-critical decisions involving large, dynamic data sets must be made [93.2, 46].

SNfactory astrophysicists are currently using Sunfall and the Supernova Warehouse regularly for their scientific work. We have documented numerous favorable comments on the interface, and noted in user observations that less time is spent on routine tasks [93.2, 43]. Perhaps the most revelatory critique is that the scientists have ceased using all other legacy tools that SNwarehouse was intended to replace, and they continue to use the Sunfall framework even though the software developers have moved on to other projects [93.2, 36].

Finally, perhaps one of the most important lessons to be learned from this case study is the importance of forming closely integrated, interdisciplinary teams where members from all fields are involved in the participatory design process from the beginning of the project. Designing effective interfaces for complex, time-critical scientific decision-making requires both domain expertise and software expertise, and the two must be closely intertwined for the ultimate success of the project. Computer scientists and physicists all participated in both the scientific research and the software development process, which included regular group meetings and informal code reviews, thus facilitating the marriage of sophisticated science algorithms with software engineering best practices. Sunfall is highly usable software that has received praise from project scientists and has increased user satisfaction, efficiency, and productivity. Most important of all, Sunfall has facilitated the production of scientific data, results, and publications – the bottom line of science.

93.6.1 Future Research Directions

Since many scientists prefer to develop their own software, and indeed, find writing code a requirement to accomplish their scientific work, the scientific domain has characteristics that are very distinct from the world of commercial software development. In previous decades, scientists have written their own code, frequently developing software individually and for their own use. However, as the complexity and volume of scientific data sets continue to explode, processing requirements have been growing too intricate for single-user development. As a result, teams of computer scientists and software engineers have been brought in to implement software packages according to scientists' specifications. Nonetheless, due to the nature of scientific research and the uncertainty of the final structure of science data sets, there have still been pitfalls in this approach. One challenge is that specifications are constantly evolving, and some scientific needs cannot be articulated before the scientists are actually working with the data.

Because of this, tightly coupled communication and feedback are becoming more and more necessary, and participatory design can yield substantial benefits. The scientists we worked with believe that interdisciplinary teams of software developers will become more common in future data-intensive science projects. There was agreement that computer scientists should be *embedded* as full collaborators in science projects, so that *my problems become your problems*. At the same time, participatory design allows scientists to be an active part of the design process and gives them a sense of ownership of the software.

As scientific projects are being deluged with exponentially growing quantities of increasingly complex and dynamic data, there has been a corresponding acceleration in the rate of change in the scientific culture of software development. The escalating pace of scientific discovery is being accompanied by new, interdisciplinary approaches to scientific computation, with a resulting influx of paradigms from relatively young disciplines such as human–computer interaction and usability engineering.

Although scientists have typically not ranked usability as a major concern in software design, we believe that is changing. We would like to see further case studies of large-scale scientific projects as they take usability into account throughout the design and implementation of their computing frameworks. We believe study of the human interface to scientific software will become especially critical for data-intensive science projects as the gap between the exponential growth of scientific data and the relatively unchanging nature of human cognitive capacity continues to expand. We call for continued research into the area of scientist–computer interaction.

Part J

Appendix

Part J Appendix

Appendix. Part J The concluding part of this Handbook contains figures and tables with statistical information and summaries about automation applications and impacts in three main areas: industrial automation; service automation; and financial and e-Commerce automation. A rich list of associations and of periodical publications around the world that focus on automation in its variety of related fields is also included for the benefit of readers worldwide.

94. Automation Statistics

Juan D. Velásquez, Xin W. Chen, Sang Won Yoon, Hoo Sang Ko

This chapter contains automation information collected from many different sources around the world, among them the US Census Bureau, the International Federation of Automatic Control (IFAC), the American Automatic Control Council (AACC), the American Bankers Association, World Robotics, and many more. Section 94.1 introduces automation statistical data according to its application domain, such as: financial and e-Commerce, industrial, healthcare, and the service industries. In Sect. 94.2 a list of worldwide automation, control, and robotics associations is provided. Section 94.3 provides the reader with a list of automation labs around the world and lastly, in Sect. 94.4 a list of automation related journals and publications is presented.

The statistics, organizations, and journals included in this chapter open a window into the current and emerging state of automation. While attempting to be comprehensive, because of the broadness of automation, the authors recognize that there may be additional relevant items, but none were omitted intentionally. The scope of the information is meant to highlight and expose the broad span, applications, concerns and benefits of automation, and clearly, cannot completely include all areas of automation influence. Beyond this chapter, other chapters in this handbook provide additional statistical data directly related to their specific topic.

Automation continues to enable individuals, companies, and governments to innovate and compete in a fast-changing world. Companies of all sizes throughout the world in virtually all industries have embraced automation as one of the most powerful strategic advantages to stay competitive. For instance, in robotic automation it is expected that over 1 million robots will be installed worldwide by 2011, a significant gain from the 400 000 that were installed in the early 1990s. Japan, the USA, and Germany will continue to supply the majority of robots, while automotive parts and motor vehicles will continue to demand the greatest number of robots by industry.

It has not only been companies that are taking advantage of automation; individuals have also embraced automation as a way to enhance their everyday lives. It is expected that, by 2012, consumers' most used payment form will be electronic transfers, followed by credit cards. More than 50% of all travel reservations made in the USA are now done by consumers directly via the Internet rather than by travel agencies. Likewise, the number of online buyers continues to climb, with over 50% of Americans having bought at least one product online in 2007. It is projected that in the USA alone e-Commerce will grow from US$ 282.7 billion in 2007 to US$ 658.4 billion by 2010, almost a threefold increase in 3 years.

What does the future hold for automation? Automation's influence on microsystems, nanosystems, and systems-of-systems will explode, as will bioinspired automation and bioinspired collaborative control. There are many grand challenges as identified by the US National Academy of Engineering for which automation is essential (i. e., make solar energy economical, advance personalized learning, engineer better medicines). For instance, virtual reality will significantly influence healthcare, engineering, entertainment, and education and training as its worldwide market grows from US$ 2 billion in 2002 to over US$ 8 billion in 2010.

94.1 Automation Statistics

94.1.1 Financial and e-Commerce Automation

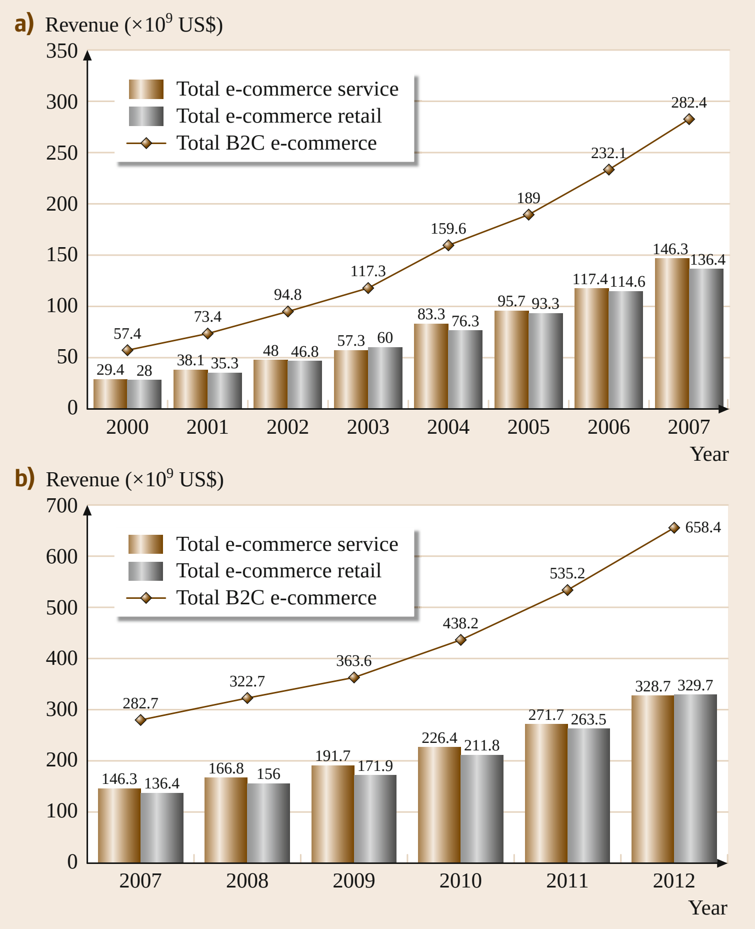

Fig. 94.1a,b Business-to-consumer e-Commerce **(a)** revenue by service and retail sectors for 2000–2007 in US$. **(b)** Projected revenue by service and retail sectors for 2007–2012 in US$ (source: US Department of Commerce, US Census Bureau)

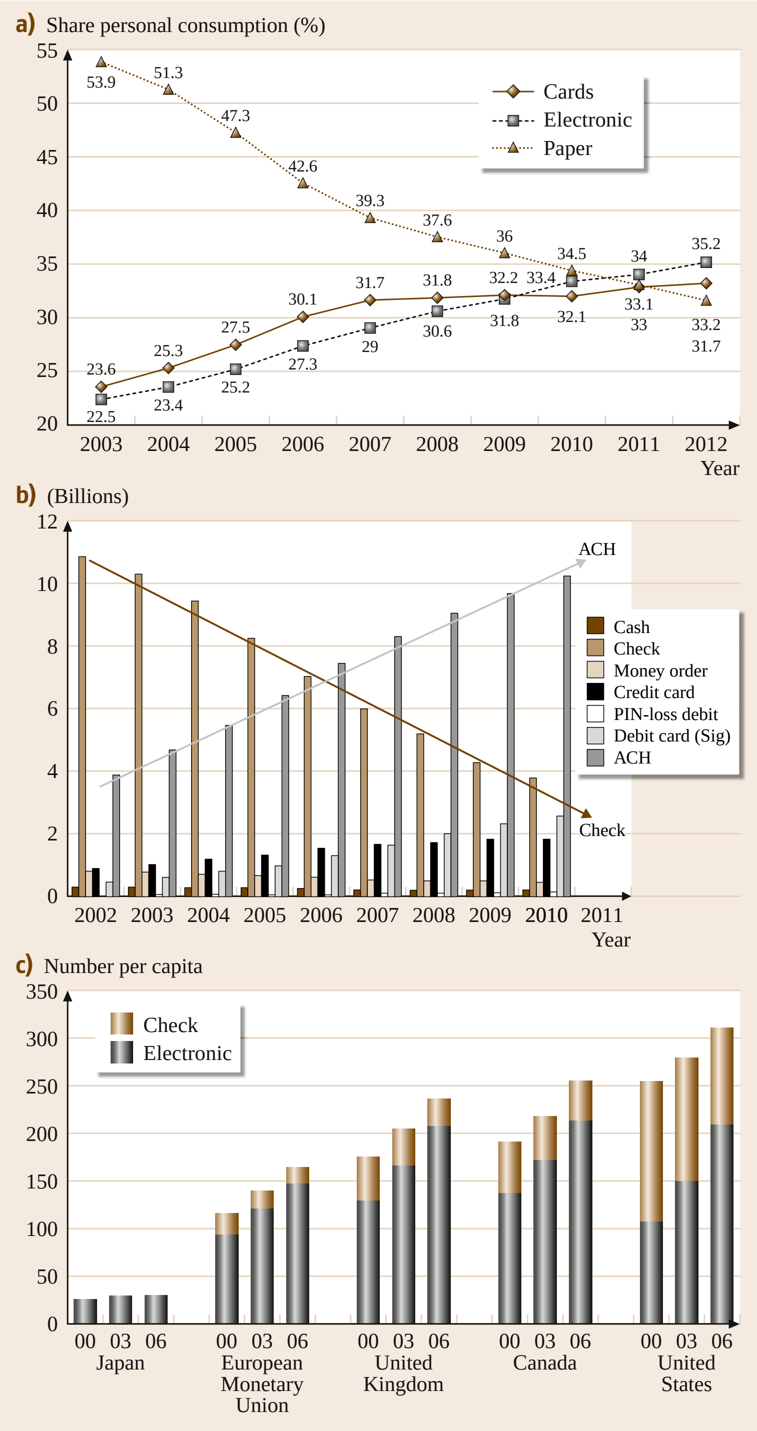

Fig. 94.2a–c e-Commerce payments. **(a)** Estimated share of US personal consumption by credit cards, electronic payments, and paper from 2003–2012 (projected) (source: US Department of Commerce, US Census Bureau), note: paper includes cash, check, money orders, etc. Cards includes both credit and debit purchase volume. Electronic includes pre-authorized, recurring payments, payments made via telephone, and payments initiated via the Internet **(b)** Total Number of consumer to business recurring payments by industry in the US from 2002 to 2010 in US$ (source: Celent and Bearing Point Analysis) **(c)** Non-cash payments per-capita in five selected economies in 2000, 2003 and 2006. The European Monetary Union is made up of Austria, Belgium, Finland, France, Germany, Greece, Ireland, Italy, Luxemburg, The Netherlands, Portugal, and Spain. Cyprus, Malta, and Slovenia joined the EMU after 2006 and were not included in calculations (sources: European Central Bank (2007), Bank for International Settlements (2008), Federal Reserve Board)

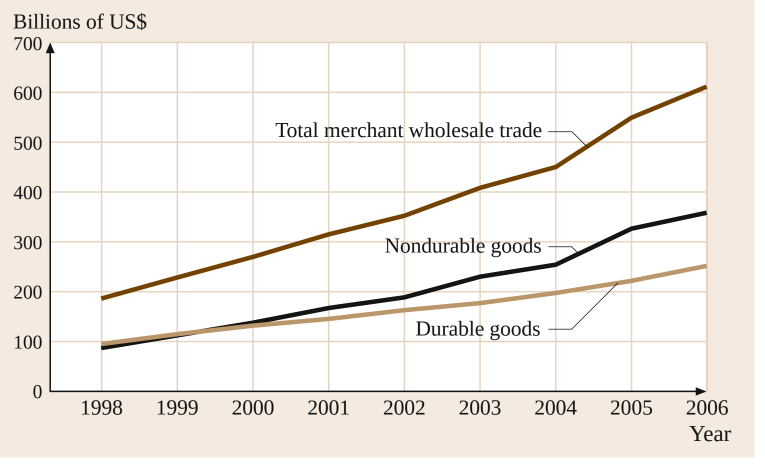

Fig. 94.3 Merchant wholesale trade e-Commerce sales in the US: 1998–2006 (source: US Census Bureau)

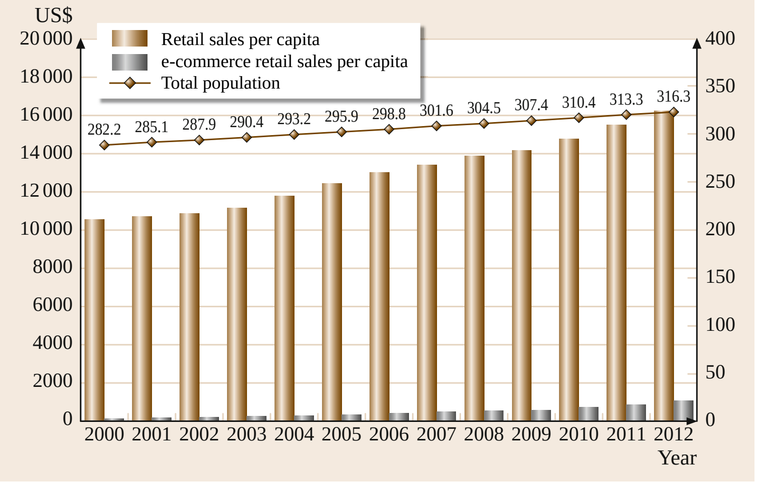

Fig. 94.4 Retail sales per capita and e-Commerce retail sales per capita from 2000 to 2012 (projected) (source: US Department of Commerce, US Census Bureau (2000–2007); population growth estimated by Cogitamus Consulting; sales per capita figures estimated by Package Facts)

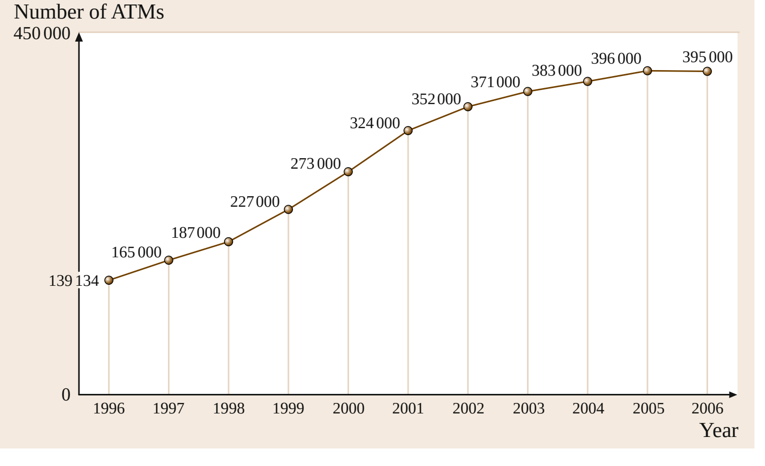

Fig. 94.5 Number of automated teller machines (ATMs) in the US from 1996 through 2006 (source: American Bankers Association, 2007 ATM Fact Sheet, with permission)

94.1.2 Industrial Automation

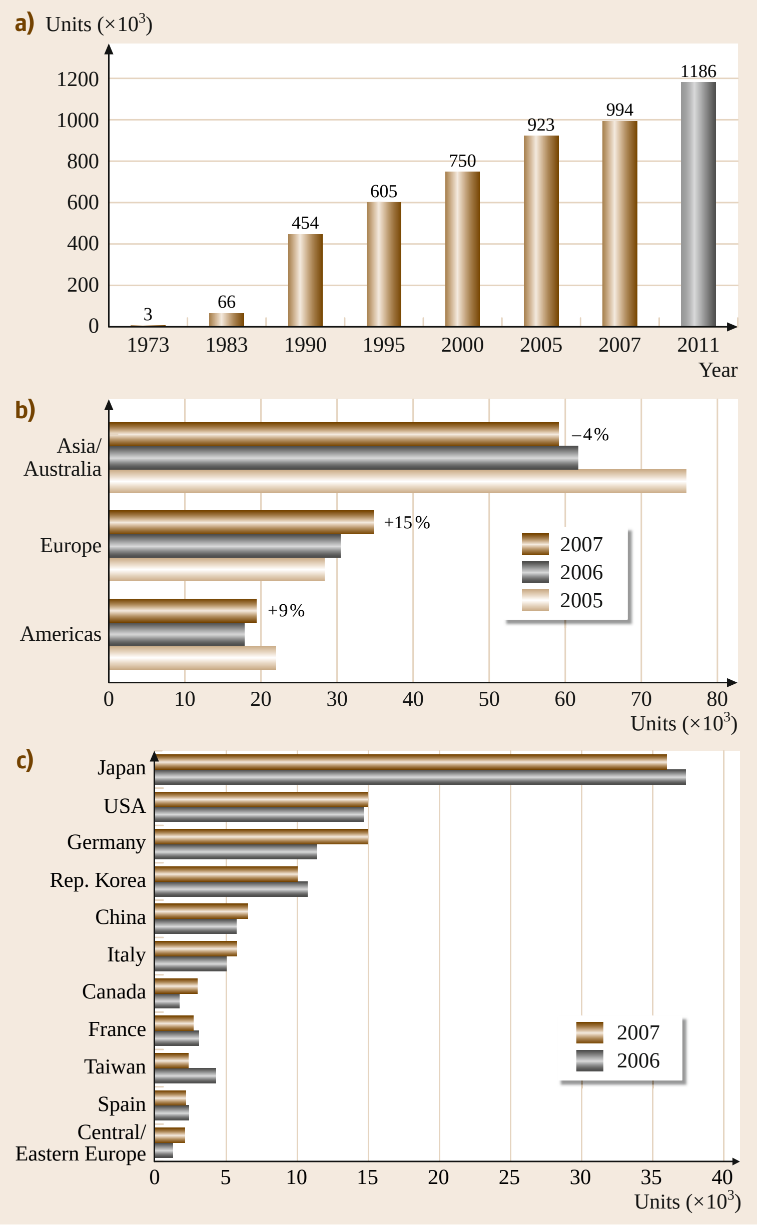

Fig. 94.6 Figures **(a–d)** illustrate growth in industrial automation. **(a)** Estimated and projected worldwide operational stock of industrial robots. **(b)** Estimated yearly supply of industrial robots by regions of the world from 2005 to 2007. **(c)** Estimated yearly supply of industrial robots by selected countries (source: World Robotics, 2008)

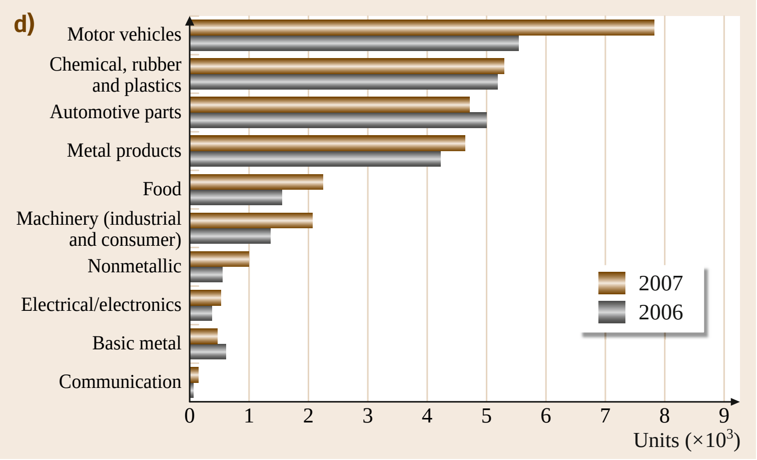

Fig. 94.6 **(d)** Estimated yearly supply of industrial robots in Europe by robot implementation areas (source: World Robotics, 2008)

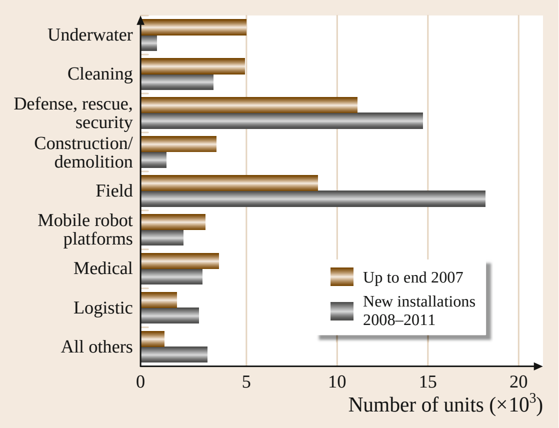

Fig. 94.7 Current and projected installations and stock of service robots for professional use up to 2006 and projected sales for the period 2008–2011 (source: World Robotics, 2008)

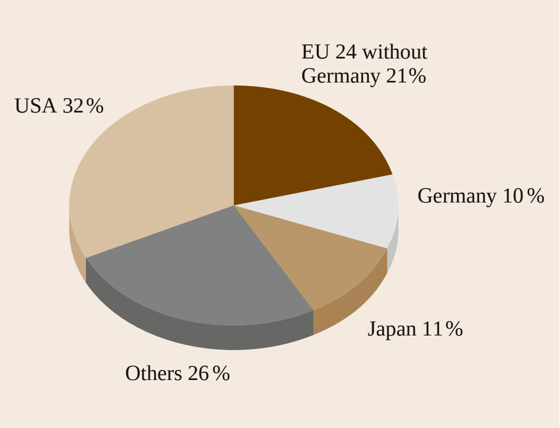

Fig. 94.8 Process automation in the world (source: ZVEI, Zentralverband Elektrotechnik- und Elektronikindustrie e.V., Frankfurt)

A.3 Automation: What It Means to Us Around the World

by Shimon Y. Nof

I received with appreciation help in preparing and reviewing this chapter from my graduate students at our PRISM Center, particularly Xin W. Chen, Juan Diego Velásquez, Sang Won Yoon, and Hoo Sang Ko, and my colleagues on our PRISM Global Research Network, particularly Professors Chin Yin Huang, José A. Ceroni, and Yael Edan. This chapter was written in part during a visit to the Technion, Israel Institute of Technology in Haifa, where I was inspired by the automation collection at the great Industrial Engineering and Management Library. Patient and knowledgeable advice by librarian Coral Navon at the Technion Elyachar Library is also acknowledged.

A.7 Impacts of Automation on Precision

by Alkan Donmez, Johannes A. Soons

This contribution was prepared by employees of the US Government as part of their official duties and is, therefore, a work of the US Government and not subject to copyright.

B.14 Artificial Intelligence and Automation

by Dana S. Nau

This work has been supported in part by DARPA's Transfer Learning and Integrated Learning programs, NSF grant IIS0412812, AFOSR grant FA95500610405 and NAVAIR contract N6133906C0149. The opinions in this paper are those of the authors and do not necessarily reflect the opinions of the funders.

B.16 Automation of Mobility and Navigation

by Anibal Ollero, Ángel R. Castaño

The work described in this chapter has been supported by various projects including the European projects COMETS (IST-2001-34304) and AWARE (IST-2006-33579) and the Spanish projects ROBAIR (DPI2008-03847), AEROSENS (DPI2005-02293), and SIRE (2006, TEP-375).

C.19 Mechatronic Systems – A Short Introduction

by Rolf Isermann

This chapter is revised from Isermann, R. (2008), Mechatronische Systeme. 2. Auflage. Springer-Verlag, Berlin, and Isermann, R. (2005), Mechatronic Systems. Springer-Verlag, London.

C.26 Collaborative Human–Automation Decision Making

by Mary L. Cummings, Sylvain Bruni

This research was sponsored by the Office of Naval Research Long-Range Navy and Marine Corps Science and Technology Research Opportunity (BAAs 04-001 and 07-001). The views and conclusions presented in this chapter are those of the authors and do not represent an official opinion, expressed or implied, of the Office of Naval Research. Special thanks to Jessica J. Marquez, Amy Brzezinski, Carl Nehme, and Yves Boussemart who were co-creators of HACT and for the reviews by Prof. John Lee from the University of Iowa, Prof. Gilles Coppin from the Ecole Nationale Supérieure des Télécommunications de Bretagne, France, and Prof. Duncan Campbell from Queensland University of Technology, Australia.

C.27 Teleoperation

by Luis Basañez, Raúl Suárez

The authors would like to thank the members of the Robotics Division of the IOC, and especially Emmanuel Nuño, Henry Portilla, Máximo Roa, Adolfo Rodríguez, and Carlos Rosales, for their great collaboration in the preparation of this chapter.

This work has been partially supported by the CICYT projects DPI2005-00112 and DPI2007-63665.

C.28 Distributed Agent Software for Automation

by Francisco P. Maturana, Dan L. Carnahan, Kenwood H. Hall

We would like to thank AvPro Incorporated and GKN Aerospace for their technical support on the understanding of composite curing technology.

C.30 Automating Errors and Conflicts Prognostics and Prevention

by Xin W. Chen, Shimon Y. Nof

This chapter has been developed with the support of the PRISM Center and the School of Industrial Engineering at Purdue University. Partial support by General Motors Research project on Design of Active Middleware for Error and Conflict Detection is also acknowledged.

D.35 Machining Lines Automation

by Xavier Delorme, Alexandre Dolgui, Mohamed Essafi, Laurent Linxe, Damien Poyard

The industrial case plus the illustrations of the parts and machining units presented in this chapter were provided by the society PCI/SCEMM (http://www.pci.fr/). The authors thank Dr. Olga Guschinskaya for her advice and discussions and Chris Yukna for his help in English.

E.40 Economic Rationalization of Automation Projects

by José A. Ceroni

The author gratefully acknowledges the significant and valuable contributions of Y. Hasegawa, J. Mill, G. T. Stevens, B. Huff, and A. Presley for their previous work on this topic.

E.43 Product Lifecycle Management and Embedded Information Devices

by Dimitris Kiritsis

The content of this chapter is based on reports and publications of the PROMISE project (EU FP6 507100 and IMS 01008; www.promise-plm.com). The author expresses his deep gratitude to all PROMISE partners.

E.47 Automation and Ethics

by Srinivasan Ramaswamy, Hemant Joshi

The authors wish to thank the anonymous reviewers and editors for significant help and advice in writing this chapter. Parts of this work were supported in part by the National Science Foundation (under Grant Nos. CNS-0619069, EPS-0701890 and OISE 0729792), NASA EPSCoR Arkansas Space Grant Consortium (#UALR 16804) and Acxiom Corporation (#281539). Any opinions, findings, and conclusions or recommendations expressed in this chapter are those of the author(s) and do not necessarily reflect the views of the funding agencies. Finally, the authors would like to thank Sithu Sudarsan, currently a visiting researcher at the FDA's Center for Devices and Radiological Health, for engaging discussions on this subject.

F.49 Digital Manufacturing and RFID-Based Automation

by Wing B. Lee, Benny C.F. Cheung, Siu K. Kwok

The authors would like to express their sincere thanks to the Research Committee of The Hong Kong Polytechnic University (project code G-YE31) and the Innovation and Technology Commission (ITC) of The Government of the Hong Kong Special Administrative Region (HKSAR) (project code GHS/091/04) for financial and technical support of the research work.

F.51 Aircraft Manufacturing and Assembly

by Branko Sarh, James Buttrick, Clayton Munk, Richard Bossi

Ron Gill, Michael Watts, Larry Hefti, and Robert A. Kisch also contributed to this chapter. Bruce Harman of Boeing served as chapter editor.

F.54 Production, Supply, Logistics and Distribution

by Rodrigo Cruz Di Palma, Manuel Scavarda Basaldúa

Technical and theoretical contributions by Sang-Won Yoon from the PRISM Center at Purdue University are acknowledged. Additional support and contributions for this chapter were provided by Guillermo Pinochet, Cristian Hernandez, and Craig Downing.

G.67 Air Transportation System Automation

by Satish C. Mohleji, Dean F. Lamiano, Sebastian V. Massimini

The authors gratefully acknowledge valued support from Dr. D. Bhadra, W. W. Cooper, J. C. Celio, Dr. D. B. Kirk, R. O. Lejeune, E. G. Newberger, W. J. Swedish, G. H. Solomos, and Dr. A. D. Zeitlin of MITRE/CAASD, and W. Flathers of United Airlines.

Thanks to A. Signore for preparing the manuscript. The authors thank Dr. C. R. Wanke for peer-reviewing the content presented in this chapter.

H.75 Automatic Control in Systems Biology

by Henry Mirsky, Jörg Stelling, Rudiyanto Gunawan, Neda Bagheri, Stephanie R. Taylor, Eric Kwei, Jason E. Shoemaker, Francis J. Doyle III

The authors gratefully acknowledge significant editorial help in preparing this chapter by Xin W. Chen from the PRISM Center at Purdue University. The authors also gratefully acknowledge financial support from the Institute for Collaborative Biotechnologies (ICB) through the United States Army Research Office (ARO) (Grants DAAD19-03-D-0004 and W119NF-07-1-0279), from the National Institutes of Health (NIH) (Grants EB007511 and GM078993), from the Integrative Graduate Education Research Traineeship National Science Foundation (IGERT NSF) (Grant DGE02-21715), from the Defense Advanced Research Projects Agency (DARPA) BioComp and BioSpice Programs, from the Research Participation Program between the United States Department of Energy (DOE) and Air Force Research Laboratory, Human Effectiveness Directorate (AFRL/HEP), and from the University of California, Board of Regents.

H.79 Rotary Heart Assist Devices

by Marwan A. Simaan

This research was supported in part by NSF under grants ECS-0300097 and ECCS-0701365 and NIH/BHLBI under contract 1R43HL66656-01. The contributions of Drs. James F. Antaki and J. Robert Boston and our students Leonardo Baloa, Darryl Breitenstein, Shaohui Chen, Antonio Ferreira, and Yih-Chong Yu are gratefully acknowledged.

H.80 Medical Informatics

by Chin-Yin Huang

The author would like to thank Chen Ching General Hospital and DVNET Technologies Co. for providing the precious pictures in this chapter. Research projects 93-2218-E-029-001 and 94-2213-E-029-013 are also gratefully acknowledged for the knowledge discovery on breast cancer patient records, supported by the National Science Council, Taiwan.

H.81 Nanoelectronic-Based Detection for Biology and Medicine

by Samir M. Iqbal, Rashid Bashir

The authors would like to acknowledge and thank Oguz H. Elibol and Bala Murali K. Vekatesan for help with literature collection, and Salman B. Inayat and Syed H. Shah for manuscript review. S.M. Iqbal acknowledges support from University of Texas at Arlington Research Enhancement Program.

I.85 Automation in Education/Learning Systems

by Kazuyoshi Ishii, Kinnya Tamaki

The case studies were supported by The Research Center for e-Learning Professional Competency (eLPCO) in the Research Institute of Aoyama Gakuin University and The Research Center for Social and Industrial Management Systems of Kanazawa Institute of Technology. We would like to thank the staff of the organization for their cooperation with these studies. Also, one of the cases was supported in part by a grant-in-aid for Scientific Research of the Japanese Ministry of Education, Culture, Sports, Science, and Technology under contract number C19510160 (2007–2008).

I.88 Collaborative e-Work, e-Business, and e-Service

by Juan D. Velásquez, Shimon Y. Nof

Research reported in this chapter has been developed at the PRISM Center of Purdue University with NSF, Indiana 21st Century fund for Science and Technology, and substantial industry support.

Special thanks are due to: our colleagues, our visiting scholars, and the many students at the PRISM Lab and the PRISM Global Research Network worldwide; and the International Foundation of Production research (IFPR) and the International Federation of Automatic Control (IFAC) Committee CC5 for Manufacturing and Logistics Systems, many of whom are also chapter co-authors in this Handbook. They have all collaborated with us to develop, over many years, e-work and collaborative control theory knowledge.

I.92 e-Government

by Dieter Rombach, Petra Steffens

The authors would like to thank the following persons for valuable comments, enlightening discussion, and help in producing this chapter: Prof. Dr. Frank Bomarius, Savitha Chennagiri, Ines Grützner, Thomas Jeswein, Dr. Jürgen Münch, Dr. Reinhard Schwarz, and Dr. Michael Tschichholz.

I.93 Collaborative Analytics for Astrophysics Explorations

by Cecilia R. Aragon

The author would like to thank the Sunfall developers and scientists of the SNfactory collaboration, in particular Greg Aldering, Stephen Bailey, Karl Runge, Sarah Poon, and Rollin Thomas. This work was supported in part by the Director, Office of Science, Office of Advanced Scientific Computing Research, of the US Department of Energy under Contract No. DE-AC02-05CH11231, and by the Director, Office of Science, Office of High Energy Physics, of the US Department of Energy under Contract No. DE-FG02-92ER40704, and by a grant from the Gordon & Betty Moore Foundation. This research used resources of the National Energy Research Scientific Computing Center, which is supported by the Office of Science of the US Department of Energy under Contract No. DE-AC02-05CH11231.

J.94 Automation Statistics

by Juan D. Velásquez, Xin W. Chen, Sang Won Yoon, Hoo Sang Ko

The authors wish to thank all the many colleagues and sources who helped in developing this chapter. At the same time, while we did our best to be comprehensive, we apologize if we mistakenly missed any relevant data. We will be able to include it in future editions.

About the Authors

Nicoletta Adamo-Villani

Purdue University
Computer Graphics Technology
West Lafayette, IN, USA
nadamovi@purdue.edu

Chapter D.37

Nicoletta Adamo-Villani is Associate Professor of Computer Graphics Technology at Purdue University. She received her MS in Architecture from University of Florence, Italy in 1993 and she is a certified 3-D modeller/animator for Autodesk. Adamo-Villani is an award-winning animator and creator of 2-D/3-D films that aired on national television. Her research interests focus on the application of 3-D animation to education, HCC (human–computer communication), and visualization.

Panos J. Antsaklis

University of Notre Dame
Department of Electrical Engineering
Notre Dame, IN, USA
antsaklis.1@nd.edu

Chapter B.13

Panos J. Antsaklis is the Brosey Professor of Electrical Engineering and Concurrent Professor of Computer Science and Engineering at the University of Notre Dame. His research interests are in control and automation, particularly in networked control and hybrid systems emphasizing interdisciplinary research in control, computing and communication networks. He has authored books on Linear Systems, Discrete Event, Hybrid and Networked Control Systems.

Cecilia R. Aragon

Lawrence Berkeley National Laboratory
Computational Research Division
Berkeley, CA, USA
CRAragon@lbl.gov

Chapter I.93

Cecilia Aragon is a Staff Computer Scientist in the Computational Research Division at Lawrence Berkeley National Laboratory. Her research interests include visualization, image processing, visual analytics, computer-supported cooperative work, and human–computer interaction. She received her PhD in computer science from the University of California, Berkeley and her BS in mathematics from the California Institute of Technology. She is a Senior Member of the IEEE.

Neda Bagheri

Massachusetts Institute of Technology (MIT)
Department of Biological Engineering
Cambridge, MA, USA
nbagheri@mit.edu

Chapter H.75

Neda Bagheri earned her MS/PhD (2007) in Electrical Engineering from the University of California Santa Barbara with emphasis in Control Theory and Systems Biology. As a postdoctoral researcher at MIT, she currently investigates combinatorial cancer therapy through dynamical systems modeling integrated tightly with quantitative experiments. Her primary research interest focuses on addressing challenges in medicine and biology using principles from control theory.

Greg Baiden

Laurentian University
School of Engineering
Sudbury, ON, Canada
gbaiden@laurentian.ca

Chapter F.57

Dr. Baiden is a Mining Professor specializing in robotics and mining automation in the School of Engineering at Laurentian University. Dr. Baiden lead mining research at Inco Ltd prior to joining Laurentian University and creating Penguin Automated Systems Inc. His research investigates robotics and automation for many types of systems such as underground, surface, underwater and in space. His recent work includes the newly patented high bandwidth communication systems.

Parasuram Balasubramanian

Theme Work Analytics Pvt. Ltd.
Bangalore, India
balasubp@gmail.com

Chapter G.71

Parasuram Balasubramanian holds engineering and management degrees from IIT, Madras and a doctorate from Purdue University. He has been with the Information Technology industry in India, Jamaica and USA and has been a featured speaker in many conventions. He specializes in business analytics and plays a proactive role to bridge industry and academia on the research front.

P. Pat Banerjee

University of Illinois
Department of Mechanical
and Industrial Engineering
Chicago, IL, USA
banerjee@uic.edu

Chapter B.15

P. Pat Banerjee has a B.Tech from the Indian Institute of Technology, a PhD from Purdue University and is a Fellow of the ASME. His current research interests include virtual reality and haptics applications. Currently he is an Associate Editor of IEEE Transactions for Information Technology in Biomedicine. With over 100 refereed publications, he has served as a department editor of IIE Transactions, and as an associate editor of IEEE Transactions on Robotics and Automation.

Ruth Bars

Budapest University of Technology
and Economics
Department of Automation and Applied
Informatics
Budapest, Hungary
bars@aut.bme.hu

Chapter B.10

Ruth Bars graduated at the Electrical Engineering Faculty of the Technical University of Budapest, Hungary. She has gained the candidate of sciences degree from the Hungarian Academy of Sciences in 1992 and the PhD degree based on research in predictive control. Currently she is an Associate Professor in the Department of Automation and Applied Informatics at the Budapest University of Technology and Economics. Her research interests are in predictive control and in developing new ways of control education.

Luis Basañez

Technical University of Catalonia (UPC)
Institute of Industrial and Control
Engineering (IOC)
Barcelona, Spain
luis.basanez@upc.edu

Chapter C.27

Luis Basañez is full Professor of System Engineering and Automatic Control at the Technical University of Catalonia, head of the Robotics Division of the Institute of Industrial and Control Engineering, Spanish delegate at the International Federation of Robotics, and fellow and Council member of the International Federation of Automatic Control. His present research interest includes teleoperation, multirobot coordination, sensor integration and active perception.

Rashid Bashir

University of Illinois
at Urbana-Champaign
Department of Electrical and Computer
Engineering and Bioengineering
Urbana, IL, USA
rbashir@uiuc.edu

Chapter H.81

Rashid Bashir is the Abel Bliss Professor of Electrical and Computer Engineering and Bioengineering and Director of the Micro- and Nanotechnology Laboratory at the University of Illinois, Urbana-Champaign. His research interests include BioMEMS, Lab on a chip, nano-biotechnology, and interfacing biology and engineering from molecular to tissue scale.

Wilhelm Bauer

Fraunhofer-Institute
for Industrial Engineering IAO
Corporate Development
and Work Design
Stuttgart, Germany
wilhelm.bauer@iao.fraunhofer.de

Chapter D.34

Wilhelm Bauer graduated in Industrial Engineering from the University of Stuttgart and received the Dr.-Ing. degree from the same University. As a Scientific Director he is heading the business area Corporate Development and Work Design at IAO and IAT. His research activities include work sciences, knowledge work, virtual work spaces, office innovations and change management. He is lecturer for Work Design at the Universities of Hannover and Stuttgart.

Gary R. Bertoline

Chapter D.37

Purdue University
Computer Graphics Technology
West Lafayette, IN, USA
Bertoline@purdue.edu

Dr. Gary R. Bertoline is a Distinguished Professor of Computer Graphics Technology at Purdue University. Gary's research interests are in scientific visualization, interactive immersive environments, distributed and grid computing and STEM education. He has authored numerous papers on engineering and computer graphics, computer-aided design, and visualization research. He has authored and co-authored seven textbooks in the areas of computer-aided design and engineering design graphics.

Christopher Bissell

Chapter A.4

The Open University
Department of Communication
and Systems
Milton Keynes, UK
c.c.bissell@open.ac.uk

Christopher Bissell graduated from Jesus College, Cambridge in 1974 and obtained his PhD from the Open University in 1993, where he has been employed since 1980. He has written much distance teaching material on telecommunications, control engineering, digital media and other topics. His major research interests are the history of technology and engineering education.

Richard Bossi

The Boeing Company
Renton, WA, USA
richard.h.bossi@boeing.com

Chapter F.51

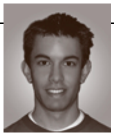
Richard H. Bossi received his Bachelor's degree in physics from Seattle University in 1971 and his PhD from Oregon State University in Nuclear Engineering in 1977. He is a Senior Technical Fellow for Nondestructive Evaluation (NDE) on the physics staff at The Boeing Company. His primary research is in the application NDE technology for materials characterization.

Martin Braun

Fraunhofer-Institute
for Industrial Engineering IAO
Human Factors Engineering
Stuttgart, Germany
martin.braun@iao.fraunhofer.de

Chapter D.34

Martin Braun received his University Diploma in Industrial Engineering. While being Teaching Assistant at the University of Stuttgart he graduated in OHS and earned a doctorate in Human Factors Management. Since 1999 he is working as a project manager at Fraunhofer-Institute for Industrial Engineering (IAO) in the field of human factors engineering and work design. His main activities in applied research are human performance, mental work and occupational health. Martin Braun is lecturer at the University of Stuttgart and has authored more than 100 publications.



Sylvain Bruni

Chapter C.26

Aptima, Inc.
Woburn, MA, USA
sbruni@aptima.com

Sylvain Bruni is a Human Systems Engineer at Aptima, where he provides expertise in human-automation interaction, interface design, and the statistical design of experiment. His research also focuses on designing and testing collaborative decision-support systems, specifically in military command and control environments. He earned a SM in Aeronautics/Astronautics from MIT and a Diplôme d'Ingénieur from Supélec (France). He is currently pursuing a PhD at MIT, in the Humans and Automation Laboratory.

James Buttrick

Chapter F.51

The Boeing Company
BCA – Materials & Process Technology
Seattle, WA, USA
james.n.buttrick@boeing.com

James is a Technical Fellow at Boeing Commercials' Manufacturing&Process Technology organization. He specializes in the development of automated manufacturing equipment and processes for aircraft production. He received his BS in Marine Engineering from the United States Merchant Marine Academy, and his MS in Mechanical Engineering from the University of Washington.

Darwin G. Caldwell

Istituto Italiano Di Tecnologia
Department of Advanced Robotics
Genova, Italy
Darwin.Caldwell@iit.it

Chapter F.60

Darwin G. Caldwell (BSc 1986, PhD 1990, University of Hull) is a Director at the Italian Institute of Technology, Genoa, Italy, and an Honorary Professor at the Universities of Sheffield, Manchester and Wales, Bangor. His research interests include innovative actuators and sensors, haptic feedback, force augmentation exoskeletons, dexterous manipulators, humanoid (iCub) and quadrapedal robots, biomimetic systems, rehabilitation robotics, telepresence, automation for the food industry.

Brian Carlisle

Precise Automation
Auburn, CA, USA
brian.carlisle@preciseautomation.com

Chapter F.50

Mr. Brian Carlisle is the CEO of Precise Automation, which builds assembly robots and controls. Formerly he was CEO of Adept Technology from 1983 to 2003 known for assembly automation for electronics, automotive and telecommunications products. In the late 1970s Carlisle was a project manager for the development of the PUMA robot at Unimation. Carlisle was President of the United States Robotic Industries Association for 3 years.

Dan L. Carnahan

Rockwell Automation
Department of Advanced Technology
Mayfield Heights, OH, USA
dlcarnahan@ra.rockwell.com

Chapter C.28

Mr. Carnahan is a program manager for Rockwell Automation, Advanced Technology. He has over 30 years experience working in industrial controls and automation, having previously worked in different roles ranging from development engineering to project management. He has a BSEE from Ohio State University (1972) and is a registered professional engineer in the State of Ohio, a member of the National Society for Professional Engineers, IEEE, ISA, SAE, and SEMI.

Ángel R. Castaño

Universidad de Sevilla
Departamento de Ingeniería de Sistemas
y Automática
Sevilla, Spain
castano@us.es

Chapter B.16

Ángel R. Castaño received the MEng degree in Telecommunications Engineering and the PhD degree in Automation, Robotics and Telematics from the University of Seville. He has participated in more than 20 projects, including 5 projects funded by the European Commission. His research interests are mainly in multirobot and intelligent transportation systems. He is currently an Assistant Professor at the University of Seville.

Daniel Castro-Lacouture

Georgia Institute of Technology
Department of Building Construction
Atlanta, GA, USA
dcastro6@gatech.edu

Chapter G.61

Daniel Castro-Lacouture (BSc Civil Engineering 1994, Universidad de Los Andes, MSc Construction Management 1999, University of Reading, PhD Construction Engineering and Management 2003, Purdue) is Associate Professor of Building Construction at Georgia Institute of Technology. His current research centres on construction technology innovation, sustainability and automation. He is a registered professional engineer and a member of ASCE and IAARC.

Enrique Castro-Leon

JF5-103, Intel Corporation
Hillsboro, OR, USA
Enrique.G.Castro-Leon@intel.com

Chapter C.24

Enrique Castro-Leon is an Enterprise Architect and Technology Strategist with Intel Digital Enterprise Group. He holds a PhD degree in Electrical Engineering and MS degrees in Electrical Engineering and Computer Science from Purdue University. He is the principal author of the book *The Business Value of Virtual Service Oriented Grids*. His research interests include large scale software integration and data centre power management strategy. He has served as a consultant for corporate and governmental organizations as well as NGOs.

José A. Ceroni

Chapter E.40

Pontifica Universidad Católica
de Valparaíso
School of Industrial Engineering
Valparaiso, Chile
jceroni@ucv.cl

José A. Ceroni graduated as an Industrial Engineer from Pontifical Catholic University of Valparaiso, Chile and received his Master of Science and PhD in Industrial Engineering from Purdue University, Indiana, USA. His research interests include collaborative production and control, industrial robotics systems, collaborative robotics agents, collaborative control in logistics systems. He is member of the Board of the International Federation for Production Research, and a member of IFAC and IEEE.

Deming Chen

Chapter D.38

University of Illinois, Urbana-Champaign
Electrical and Computer Engineering (ECE)
Urbana, IL, USA
dchen@illinois.edu

Deming Chen obtained his MS and PhD from the Computer Science Department of University of California at Los Angeles. He is currently an Assistant Professor in the ECE Department of University of Illinois, Urbana-Champaign. His research interests include CAD for FPGA, nanosystems design and synthesis, microprocessor design under process/parameter variation, and reconfigurable computing. He received the Arnold O. Beckman Research Award, the NSF CAREER Award, and a Best Paper Award from ASPDAC.

Heping Chen

ABB Inc.
US Corporate Research Center
Windsor, CT, USA
heping.chen@us.abb.com

Chapter F.53

Heping Chen received his PhD in Electrical and Computer Engineering from Michigan State University in 2004. He is currently a project manager and research scientist at US Corporate Research Center, ABB Inc. His research interests include nanomanufacturing automation and nanorobotics, industrial robot control based on sensor integration, robot path planning and machine vision. He is an IEEE Senior member.

Xin W. Chen

Purdue University
PRISM Center and School of Industrial Engineering
West Lafayette, IN, USA
chen144@purdue.edu

Chapters C.30, J.94

Xin W. Chen is a PhD Candidate in the School of Industrial Engineering at Purdue University. He received the MS degree in Industrial Engineering and BS degree in Mechanical Engineering from Purdue University and Shanghai Jiaotong University, respectively. His research interests cover several related topics in the area of conflict and error prognostics and prevention, production/service optimization, and decision analysis.

Benny C.F. Cheung

Chapter F.49

The Hong Kong Polytechnic University
Department of Industrial and Systems Engineering
Kowloon, Hong Kong
mfbenny@inet.polyu.edu.hk

Benny C.F. Cheung obtained his BEng, MPhil and PhD degrees in Manufacturing Engineering from The Hong Kong Polytechnic University in 1993, 1996 and 2000, respectively. Currently, he is an Associate Professor and an Associate Director of the Knowledge Management Research Centre in Department of Industrial and Systems Engineering of The Hong Kong Polytechnic University. His research interest includes precision engineering, knowledge and technology management, artificial intelligence and logistics systems.

Jaewoo Chung

Chapter F.55

Kyungpook National University
School of Business Administration
Daegu, South Korea
jaewooch@gmail.com

Jaewoo Chung received the PhD degree from the School of Industrial Engineering at Purdue University in 2008. He developed various production systems and facilities layouts during his work for the LCD/Semiconductor division at Samsung Electronics for about a decade. He is currently an assistant professor at Kyungpook National University, South Korea. His areas of interests are production systems and combinatorial optimization.

Rodrigo J. Cruz Di Palma

Kimberly Clark, Latin American Operations
San Juan, Puerto Rico
Rodrigo.J.Cruz@kcc.com

Chapter F.54

Rodrigo J. Cruz Di Palma graduated as an Industrial Engineer from the University of Alabama at Tuscaloosa and obtained an MBA from EADA University in Barcelona, Spain. He is currently Supply Chain Manager for Puerto Rico, and previously led the Supply and Operations Research Team for Kimberly Clark Latin-America, focusing on the development of optimization tools for the execution of business processes.

Mary L. Cummings

Massachusetts Institute of Technology
Department of Aeronautics
and Astronautics
Cambridge, MA, USA
missyc@mit.edu

Chapter C.26

Dr. Cummings received her BS in Mathematics from the US Naval Academy (1988), her MS in Space Systems Engineering from the Naval Postgraduate School (1994), and her PhD in Systems Engineering from the University of Virginia (2003). Her research interests include human supervisory control, human-unmanned-vehicle interaction and decision-making, direct-perception decision support, and the ethical and social impact of technology.

Christian Dannegger

Rottweil, Germany
cd@3a-solutions.com

Chapter C.23

Christian Dannegger has served Whitestein Technologies from 2003 to 2009 as Vice President of Logistics and Control Systems. Prior to that he served as CTO of living systems AG, which he co-founded in 1996. From 1988 to 1995 Christian developed ERP systems at Bäurer AG, where he headed the technical product development. Recognized as a visionary business-driven technologist. He holds a Master's degree in Computer Science from Furtwangen Polytechnic Institute, Germany.

Steve Davis

Istituto Italiano Di Tecnologia
Department of Advanced Robotics
Genova, Italy
steven.davis@iit.it

Chapter F.60

Steve Davis graduated from Salford University with a degree in Robotic and Electronic Engineering in 1998, and an MSc in Advanced Robotics in 2000. He then became a research fellow gaining his PhD in 2005 before moving to the Italian Institute of Technology in 2008. His research interests include actuators, biomimetics, dexterous grippers, humanoids and automation for the food industry.

Xavier Delorme

Ecole Nationale Supérieure des Mines
de Saint-Etienne
Centre Genie Industriel
et Informatique (G2I)
Saint-Etienne, France
delorme@emse.fr

Chapter D.35

Xavier Delorme received the PhD degree in Computer Science from the University of Valenciennes, France, in 2003. He has also worked at the French National Institute for Transport and Safety Research. He is currently an Associate Professor at the École Nationale Supérieure des Mines de Saint-Etienne. His research interests concern the optimization of production and transport systems.

Alexandre Dolgui

Ecole Nationale Supérieure des Mines
de Saint-Etienne
Department of Industrial Engineering
and Computer Science
Saint-Etienne, France
dolgui@emse.fr

Chapter D.35

Alexandre Dolgui received his PhD degree from the Academy of Sciences of Belarus (USSR) and Dr. hab. degree from the University of Technology of Compiègne, France. His research focuses on manufacturing line design, production planning, and supply-chain optimization. He is the author of five books, 117 journal articles and 250 conference papers.

Alkan Donmez

Chapter A.7

National Institute of Standards
and Technology
Manufacturing Engineering Laboratory
Gaithersburg, MD, USA
alkan.donmez@nist.gov

Alkan Donmez is the Group Leader of the Machine Tool Metrology Group as well as the Program Manager of the Science-Based Manufacturing program at the National Institute of Standards and Technology (NIST). He received his BS degree in Mechanical Engineering from the Middle East Technical University in Turkey and his MS and PhD degrees from Purdue University.

Francis J. Doyle III

Chapter H.75

University of California
Department of Chemical Engineering
Santa Barbara, CA, USA
frank.doyle@icb.ucsb.edu

Dr. Francis J. Doyle III holds the Duncan and Suzanne Mellichamp Chair in Process Control in the Department of Chemical Engineering at University of California, Santa Barbara. He received his BSE from Princeton (1985), C.P.G.S. from Cambridge (1986), and PhD from Caltech (1991), all in Chemical Engineering. His research interests are in systems biology, network science, modeling and analysis of circadian rhythms, drug delivery for diabetes, model-based control, and control of particulate processes.

Yael Edan

Chapter G.63

Ben-Gurion University of the Negev
Department of Industrial Engineering
and Management
Beer Sheva, Israel
yael@bgu.ac.il

Yael Edan is a Professor in the Department of Industrial Engineering and Management. She holds a BSc in Computer Engineering and MSc in Agricultural Engineering, both from the Technion-Israel Institute of Technology, and a PhD in Engineering from Purdue University. Her research is robotic and sensor performance analysis, systems engineering of robotic systems; sensor fusion, multi-robot and telerobotics control methodologies, and human–robot collaboration methods with major contributions in intelligent automation systems in agriculture.

Thomas F. Edgar

Chapter D.31

University of Texas
Department of Chemical Engineering
Austin, TX, USA
edgar@che.utexas.edu

Thomas F. Edgar is Professor of Chemical Engineering at the University of Texas at Austin and holds the George T. and Gladys Abell Chair in Engineering. Dr. Edgar received his BS in chemical engineering from the University of Kansas and a PhD from Princeton University. His research is in process modeling, control, and optimization.

Norbert Elkmann

Chapter G.70

Fraunhofer IFF
Department of Robotic Systems
Magdeburg, Germany
norbert.elkmann@iff.fraunhofer.de

Dr. techn. Norbert Elkmann graduated in Mechanical Engineering in 1993 (Bochum, Germany) and received his doctoral degree in 1999 (Vienna, Austria). From 1993 to 1997 he worked as Research Manager at the Fraunhofer IFF in Magdeburg. Since 1998 he has been the Manager of the institute's Business Unit Robotic Systems. His current research interests are mobile robots, inspection robots and safe human–robot interaction.

Heinz-Hermann Erbe (△)

Chapter E.41

Technische Universität Berlin
Center for Human–Machine Systems
Berlin, Germany

Heinz-Hermann Erbe (1937–2008) studied Aircraft Construction at Hamburg University of Applied Sciences, was Engineer at Focke Wulf GmbH (later Vereinigte Flugtechnische Werke), and studied Engineering Mechanics at TU Berlin. He received his PhD in Engineering Mechanics, was Head of Research Group at the German Federal Institute on Material Research, Berlin (1980–1986), Professor at Bremen University, and from 1986–2002 and member of the Research Center for Human–Machine Systems at TU Berlin. Professor Erbe was active for many years as leader and member of IFAC. He retired in 2002 but remained active. A favorite subject of his interest was cost-effective energy generation by windmills in remote regions.

Mohamed Essafi

Ecole des Mines de Saint-Etienne
Department Centre for Industrial
Engineering and Computer Science
Saint-Etienne, France
essafi@emse.fr

Chapter D.35

Mohamed Essafi received his Engineer Degree in Industrial Engineering from the Ecole Nationale d'Ingnieurs de Tunis, Tunisia, and his MSc from the University Paul Verlaine of Metz, France. He is a PhD student at the Ecole des Mines de Saint-Etienne, France. His research focuses on reconfigurable manufacturing-line design.

Florin-Gheorghe Filip

The Romanian Academy
Bucharest, Romania
ffilip@acad.ro

Chapter D.36

Florin-Gheorghe Filip received his MSc and PhD in control engineering from the T.U. "Politehnica" of Bucharest in 1970 and 1982, respectively. He has been with the Institute for Informatics, Bucharest since 1970. In 1991 he was elected as a member of the Romanian Academy whose vice-president he has been since 2000. His main scientific interests are hierarchical control and decision support systems. He (co)authored some 200 papers and six monographs.

Markus Fritzsche

Fraunhofer IFF
Department of Robotic Systems
Magdeburg, Germany
markus.fritzsche@iff.fraunhofer.de

Chapter G.70

In 2003 Markus Fritzsche graduated as Electrical Engineer from the University of Applied Sciences in Leipzig, Germany and the MEng degree in Biomedical Engineering from the University in Halle in 2005. He is currently a research associate at the Fraunhofer Institute for Factory Operation and Automation (IFF). His research activities enclose mobile robotic systems and human–robot interaction.

Susumu Fujii

Sophia University
Graduate School of Science
and Technology
Tokyo, Japan
susumu-f@sophia.ac.jp

Chapter F.48

Professor Fujii received Master of Engineering from Kyoto University and a PhD from University of Wisconsin, Madison, in 1967 and 1971, respectively. He is a Professor Emeritus of Kobe University and since 2006 Professor at Sophia University. His research interests include automation of manufacturing systems and system simulation, production management and control. He has been Honorary member of The Institute of Systems, Control and Information Engineers, and Fellows of JSME, and the Society of Precision Engineering and Operations Research Society of Japan.

Christopher Ganz

ABB Corporate Research
Baden, Switzerland
christopher.ganz@ch.abb.com

Chapter A.8

Christopher Ganz is Program Manager for the global control and optimization program at ABB corporate research. Before he held various R&D and product management positions in ABB's power generation business unit. He holds a doctor degree and a diploma in Electrical Engineering from ETH Zurich, Switzerland.

Mitsuo Gen

Waseda University
Graduate School of Information,
Production and Systems
Kitakyushu, Japan
gen@waseda.jp

Chapter C.29

Mitsuo Gen received BE and ME in Engineering from Kogakuin University in 1969, 1971 and 1975, respectively and the PhD degree in Informatics from Kyoto University in 2006. His research interests are genetic and evolutionary computation and applications to network design and optimization for manufacturing scheduling and logistics systems. He published three books with Dr. R. Cheng and Dr. L. Lin.

Birgit Graf

Fraunhofer IPA
Department of Robot Systems
Stuttgart, Germany
birgit.graf@ipa.fraunhofer.de

Chapter I.84

Birgit Graf received her degree in Computer Science in 1999 and completed her PhD in mobile robot navigation in 2008, both at Stuttgart University, Germany. Since 1999 she is working at Fraunhofer IPA where she is Manager of the Domestic and Personal Robots Group since 2008. Main target of her group is the development of new service robot applications and technologies.

John O. Gray

Istituto Italiano Di Tecnologia
Department of Advanced Robotics
Genova, Italy
John.Gray-2@manchester.ac.uk

Chapter F.60

John O. Gray is a visiting Professor at the Control Systems Centre, University of Manchester, and the Department of Automatic Control and Systems Engineering, University of Sheffield. His research interests include robotics, nonlinear control systems, precision electromagnetic instrumentation, and robotic systems for the food industry. Gray received a PhD from the University of Manchester in Control Engineering.

Rudiyanto Gunawan

National University of Singapore
Department of Chemical
and Biomolecular Engineering
Singapore
chegr@nus.edu.sg

Chapter H.75

Rudiyanto Gunawan received the PhD degree from University of Illinois Urbana Champaign in 2003. He joined University of California Santa Barbara in 2003 as a Postdoctoral Fellow. Since 2006, he has been an Assistant Professor in the Department of Chemical and Biomolecular Engineering, National University of Singapore. His research interests are in the model identification and analysis of biological systems.

Juergen Hahn

Texas A&M University
Artie McFerrin Dept. of Chemical
Engineering
College Station, TX, USA
hahn@tamu.edu

Chapter D.31

Juergen Hahn received his PhD from the University of Texas at Austin in 2002 and joined the Chemical Engineering Department at Texas A&M University in 2003 as an Assistant Professor. Dr. Hahn's research deals with process systems engineering with special emphasis on systems biology.

Kenwood H. Hall

Rockwell Automation
Department of Advanced Technology
Mayfield Heights, OH, USA
khhall@ra.rockwell.com

Chapter C.28

Kenwood H. Hall is a Cleveland Native and a graduate of Cleveland State University's Fenn College of Engineering. He has led the development of many of Rockwell Automations large controller systems including the new LOGIX family of integrated controllers, is one of the founding members of the Ohio ICE consortium and a member of the board for the new third frontier Wright center for Sensor Systems Engineering. He has issued 14 Patents with 50 pending applications.

Shufeng Han

John Deere
Intelligent Vehicle Systems
Urbandale, IA, USA
hanshufeng@johndeere.com

Chapter G.63

Shufeng Han received his PhD in Agricultural Engineering from University of Illinois at Urbana-Champaign in 1993. He is currently an Engineering Scientist at John Deere Intelligent Vehicle Systems. His research interests include field robotics, vehicle automation, sensors and precision agriculture. He has received 10 patents.

Nathan Hartman

Purdue University
Computer Graphics Technology
West Lafayette, IN, USA
nhartman@purdue.edu

Chapter D.37

Nathan Hartman is Associate Professor of Computer Graphics Technology at Purdue University. Research activities include applications of 3-D modelling, automated geometry creation, and 3-D data interoperability. He received the Doctor of Education degree in Technology Education from North Carolina State University. Professor Hartman is a Co-Director of the Purdue Product Lifecycle Management Center of Excellence.

Yukio Hasegawa

Waseda University
System Science Institute
Tokyo, Japan
yukioh@green.ocn.ne.jp

Chapter A.1

Yukio Hasegawa is Professor Emeritus of the System Science Institute at Waseda University, Tokyo, Japan. He has been enjoying construction robotics research since 1983 as Director of Waseda Construction Robot Research Project (WASCOR) which has impacted automation in construction and in other fields of automation. He received the prestigious first Engelberger Award in 1977 from the American Robot Association for his distinguished pioneering work in robotics and in Robot Ergonomics since the infancy of Japanese robotics. Among his numerous international contributions to robotics and automation, Professor Hasegawa assisted, as a visiting professor, to build the Robotics Institute at EPFL (Ecole Polytechnic Federal de Lausanne) in Switzerland.

Jackson He

Intel Corporation
Digital Enterprise Group
Hillsboro, OR, USA
jackson.he@intel.com

Chapter C.24

Jackson is lead architect of the Intel Digital Enterprise Group. He received his PhD and MBA degrees from the University of Hawaii. He represented Intel at OASIS, RosettaNet, and DMTF driving industry standard definitions. He published more than 20 papers on advanced enterprise solutions, service orientation, and platform manageability. Recently he co-authored a book on virtualized service-oriented grids.

Jenő Hetthéssy

Budapest University of Technology
and Economics
Department of Automation and Applied
Informatics
Budapest, Hungary
jhetthessy@aut.bme.hu

Chapter B.10

Jenő Hetthéssy received his PhD degree in 1975 from the Technical University of Budapest, Faculty of Electrical Engineering. He received his CSc degree in 1978 from the Hungarian Academy of Sciences with a thesis on the theory and industrial application of self-tuning controllers. He spent several years as a visiting professor at the Electrical Engineering Department of the University of Minnesota, USA and has published more than 70 papers.

Karyn Holmes

Chevron Corp.
Covington, LA, USA
kholmes@chevron.com

Chapter I.90

Karyn Holmes received a computer science degree and an MBA, both from Louisiana State University (LSU). While at LSU, her research interests included enterprise systems, with a focus on enterprise resource planning systems and their use in education. She currently works in Information Management at Chevron Corporation.

Clyde W. Holsapple

University of Kentucky
School of Management, Gatton College
of Business and Economics
Lexington, KY, USA
cwhols@email.uky.edu

Chapter I.89

Clyde W. Holsapple, Rosenthal Endowed Chair at the University of Kentucky. His books include *Foundations of Decision Support Systems, Decision Support Systems – A Knowledge-based Approach, Handbook on Decision Support Systems, and Handbook on Knowledge Management*. His research focuses on multiparticipant systems, decision support systems, and knowledge management.

Petr Horacek

Chapter G.65

Czech Technical University in Prague
Faculty of Electrical Engineering
Prague, Czech Republic
horacek@fel.cvut.cz

Petr Horacek received the MS and PhD degrees in Electrical Engineering from Czech Technical University in Prague, Czech Republic (CTU) in 1976 and 1985, respectively. He is currently an Associate Professor of Control Engineering at CTU. His research and industrial project activities include process modelling, simulation and optimization, process control and control applications in power systems.

William J. Horrey

Chapter D.39

Liberty Mutual Research Institute
for Safety
Center for Behavioral Sciences
Hopkinton, MA, USA
william.horrey@libertymutual.com

William Horrey received his PhD in Psychology from the University of Illinois at Urbana-Champaign in 2005. He is currently a research scientist in the Center for Behavioral Sciences at the Liberty Mutual Research Institute for Safety in Hopkinton, MA. His research interests include divided and selective attention, transportation human factors and automation.

Justus Hortig

Chapter G.70

Fraunhofer IFF
Department of Robotic Systems
Magdeburg, Germany
justus.hortig@iff.fraunhofer.de

Justus Hortig graduated in Mechanical Engineering from the Technical University of Darmstadt in 1999 and has been working in the Business Unit Robotic Systems at Fraunhofer IFF in Magdeburg since then. His focus lies on the use of service robots for façade cleaning.

Chin-Yin Huang

Chapter H.80

Tunghai University
Industrial Engineering and Enterprise
Information
Taichung, Taiwan
huangcy@thu.edu.tw

Chin-Yin Huang received the PhD degree from Purdue University in 1999. He is an Associate Professor in the Department of Industrial Engineering and Enterprise Information at Tunghai University, Taiwan. He also serves as the Director for Program for Health Administration. His research interests include applications of data mining techniques, biomedical informatics, and distributed intelligent manufacturing systems.

Yoshiharu Inaba

Chapter C.21

Fanuc Ltd.
Yamanashi, Japan
inaba.yoshiharu@fanuc.co.jp

Yoshiharu Inaba graduated from Mechanical Engineering Department of Tokyo Institute of Technology in 1973 and joined Fanuc Ltd. in 1983. He assumed the position of director in 1989 and the position of President and CEO in 2003. He received his doctoral degree in engineering from the University of Tokyo in 1999 and is the recipient of the 22nd Award of the Japan Society for Precision Engineering (2000) and the Nicolau Award of CIRP (2007).

Samir M. Iqbal

Chapter H.81

University of Texas at Arlington
Department of Electrical Engineering
Arlington, TX, USA
smiqbal@uta.edu

Samir M. Iqbal is an Assistant Professor at the University of Texas at Arlington in the Department of Electrical Engineering. He is also affiliated with the Nanotechnology Research and Teaching Facility and Department of Bioengineering. He directs the Nano-Bio Lab with focus on chip-based early diagnosis modalities, bio-inspired rapid nano-fabrication and functionalized microfluidics. He is a senior member of IEEE.

Rolf Isermann

Technische Universität Darmstadt
Institut für Automatisierungstechnik,
Forschungsgruppe Regelungstechnik
und Prozessautomatisierung
Darmstadt, Germany
risermann@iat.tu-darmstadt.de

Chapter C.19

Rolf Isermann served as Professor for Control Systems and Process Automation at the Institute of Automatic Control of Darmstadt University of Technology from 1977–2006. Since 2006 he has been Professor Emeritus and head of the Research Group for Control Systems and Process Automation at the same institution. He has published several books and his current research concentrates on fault-tolerant systems, control of combustion engines and automobiles and mechatronic systems. Rolf Isermann has held several chair positions in VDI/VDE and IFAC and organized several national and international conferences.

Kazuyoshi Ishii

Kanazawa Institute of Technology
Social and Industrial Management
Systems
Hakusan City, Japan
ishiik@neptune.kanazawa-it.ac.jp

Chapter I.85

Kazuyoshi Ishii received his PhD in Industrial Engineering from Waseda University. Dr. Ishii is a board member of the IFPR, APIEMS and the Japan Society of QC, and a fellow of the ISPIM. His interests include production management, product innovation management, and business models based on a comparative advantage.

Alberto Isidori

University of Rome "La Sapienza"
Department of Informatics and Sytematics
Rome, Italy
albisidori@dis.uniroma1.it

Chapter B.9

Alberto Isidori is Professor of Automatic Control at the University of Rome since1975 and, since 1989, also affiliated with Washington University in St. Louis. His research interests are primarily in analysis and design of nonlinear control systems. He is the author of the book *Nonlinear Control Systems* and is the recipient of various prestigious awards, which include the "Georgio Quazza Medal" from IFAC, the "Bode Lecture Award" from IEEE. He is Fellow of IEEE and of IFAC. Currently he is President of IFAC.

Nick A. Ivanescu

University Politechnica of Bucharest
Control and Computers
Bucharest, Romania
nik@cimr.pub.ro

Chapter G.64

Nick Andrei Ivanescu graduated as an Automation Engineer and received his PhD degree in Automated Systems from the University Politehnica of Bucharest in 2000. His research activities include process control, industrial automation, microcontrollers and robotics. Since 2001 he has been lecturer in the Control and Computers faculty of the University Politehnica of Bucharest.

Sirkka-Liisa Jämsä-Jounela

Helsinki University of Technology
Department of Biotechnology
and Chemical Technology
Espoo, Finland
Sirkka-l@tkk.fi

Chapter F.57

Dr. Sirkka-Liisa Jämsä-Jounela is Professor of Process Control at Helsinki University of Technology. Before joining the university she gained practical experience in working for a number of companies in the Finnish process industry. Her research activities include process modelling, simulation, monitoring and fault diagnosis as well as production control in mineral and metal processing. Prof. Jämsä-Jounela has served IFAC as Vice President among others. She is currently the Chair of the Nordic Process Control Group and a member of the Finnish Academy of Technologies.

Bijay K. Jayaswal

Agilenty Consulting Group
Minneapolis, MN, USA
bijay.jayaswal@agilenty.com

Chapter E.45

Bijay K. Jayaswal is the CEO of Agilenty Consulting Group, LLC. He has held senior executive positions for the last 25 years. He has taught engineering and management at the University of Mauritius and at California State University, Chico and has directed MBA and Advanced Management programs. He has helped introduce corporate-wide initiatives in re-engineering, Six Sigma, and Design for Six Sigma. He is a recipient of the ASQ Crosby Medal for 2007 for his book (together with Peter C. Patton) *Design for Trustworthy Software*.

Wootae Jeong

Chapter C.20

Korea Railroad Research Institute
Uiwang, Korea
wjeong@krri.re.kr

Wootae Jeong earned a PhD from Purdue University in 2006 and joined the PRISM Center since 2003. He is currently a senior researcher at Korea Railroad Research Institute and adjunct Professor at the University of Science and Technology. His research interests are in measurement and control of automation and production systems.

Timothy L. Johnson

Chapter E.42

General Electric
Global Research
Niskayuna, NY, USA
johnsontl@nycap.rr.com

Dr. Johnson served on the MIT Electrical Engineering Faculty from 1972–1980, as a Senior Scientist at BBN, Inc., from 1980–1984, and as a Manager and technical contributor at GE Research from 1984–2008, when he retired. His research interests include automation, diagnostics and service processes, and discrete event systems. He is an AACC Eckman Award recipient and an IEEE Fellow.

Hemant Joshi

Chapter E.47

Research, Acxiom Corp.
Conway, AR, USA
hemant.joshi@acxiom.com

Hemant Joshi graduated with PhD in May 2007 from the University of Arkansas at Little Rock, USA. He has published 8 papers and 2 technical reports. He currently works as Researcher at Acxiom Research Labs. His research interests are information extraction, machine learning, data mining and automated data acquisition.

Michael Kaplan

Chapter G.72

Ex Libris Ltd.
Newton, MA, USA
michael.kaplan@exlibrisgroup.com

Michael Kaplan received his PhD from Harvard University (1977). After 20 years at Harvard University and 2 years as Associate Dean at Indiana University Libraries, he has since 2000 been with Ex Libris, Ltd. He is the editor of 2 books on library automation. In 1998 he received the LITA/Library Hi-Tech Award for Outstanding Communication in Library and Information Science.

Dimitris Kiritsis

Chapter E.43

Department STI-IGM-LICP
Lausanne, Switzerland
dimitris.kiritsis@epfl.ch

Dr. Dimitris Kiritsis earned his Diploma (1980) and PhD (1987) in Mechanical Engineering from the University of Patras, Greece. Since 1989 he is with the Computer-Aided Design and Production Laboratory (LICP) of the Swiss Federal Institute of Technology in Lausanne (EPFL). His research is in the domain of modeling methods and techniques for integrated product-process-resource planning, product lifecycle information modeling and transformation to knowledge. Dr.Kiritsis is the initiator and scientific coordinator of the FP6-IP-507100 PROMISE.

Hoo Sang Ko

Chapter J.94

Purdue University
PRISM Center and School of Industrial Engineering
West Lafayette, IN, USA
ko0@purdue.edu

Hoo Sang Ko received his BS in 1999 and MS in 2003 in Mechanical Engineering at Seoul National University, South Korea. After graduation he worked for Samsung Electronics. His research interest is in computer-supported collaboration and protocol design. He is currently a doctoral candidate in the School of Industrial Engineering and a Senior Researcher in PRISM Center at Purdue University.

Naoshi Kondo

Kyoto University
Division of Environmental Science and Technology, Graduate School of Agriculture
Kyoto, Japan
kondonao@kais.kyoto-u.ac.jp

Chapter G.63

Naoshi Kondo received the MS degree and Dr. Agr. from Kyoto University in 1984 and 1988, respectively. He joined the Department of Agricultural Engineering, Okayama University as an Assistant Professor in 1985 and became an Associate Professor in 1993. He worked for Ishii Co., Ltd. as a manager in 2000 and entered Ehime University as a Professor in 2006. Since 2007 he has been a Professor at the Graduate School of Agriculture, Kyoto University. His research interests are automation, instrumentation and information in agriculture.

Peter Kopacek

Vienna University of Technology
Intelligent Handling and Robotics – IHRT
Vienna, Austria
kopacek@ihrt.tuwien.ac.at

Chapter G.74

With a cum-laude Doctors degree from Vienna University of Technology, Professor Kopacek is Head of the Institute for Handling Devices and Robotics and President of the Austrian Society for Systems Engineering and Automation. He has Doctor hc degrees from several Universities and is Corresponding member of the Saxon Academy of Sciences, Member of the German Academy of Technical Sciences, a Senior member of IEEE, and the Recipient of the Engelberger Robotics Award.

Nicholas Kottenstette

Vanderbilt University
Institute for Software Integrated Systems
Nashville, TN, USA
nkottens@isis.vanderbilt.edu

Chapter B.13

Nicholas Kottenstette, a Research Scientist, holds a MS from the Mechanical Engineering Department at MIT and a PhD in Electrical Engineering from The University of Notre Dame. He holds 11 US patents related to the design and control of (networked) embedded systems. His current research interests are in high-confidence embedded system design and the science of cyber physical systems.

Eric Kwei

University of California, Santa Barbara
Department of Chemical Engineering
Santa Barbara, CA, USA
kwei@engineering.ucsb.edu

Chapter H.75

Eric Kwei is a graduate student of Chemical Engineering at the University of California, Santa Barbara. His interests are in mathematical modeling and systems analysis of insulin signal transduction networks.

Siu K. Kwok

The Hong Kong Polytechnic University
Industrial and Systems Engineering
Kowloon, Hong Kong
mfskkwok@inet.polyu.edu.hk

Chapter F.49

S.K. Kwok received the Bachelor of Engineering and a Doctorate in Manufacturing Engineering from The Hong Kong Polytechnic University in 1991 and 1997, respectively. He is currently a Lecturer at The Hong Kong Polytechnic University. His research interests include artificial intelligence, industrial and systems engineering, information and communication technologies (ICT), logistics enabling technologies and mobile commerce.

King Wai Chiu Lai

Michigan State University
Electrical and Computer Engineering
East Lansing, MI, USA
kinglai@egr.msu.edu

Chapter F.53

Dr. King Wai Chiu Lai received his PhD and MPhil degree in Automation and Computer-Aided Engineering from The Chinese University of Hong Kong in 2005 and 2002. Currently, he is the Manager of the Nano Manufacturing Laboratory at Michigan State University. He is conducting various research projects, such as design, fabrication and application of nanooptical detectors and solar cells and development of automated micro/nanofluidic manipulation system.

Dean F. Lamiano

The MITRE Corporation
Department of Communications
and Information Systems
McLean, VA, USA
dlamiano@mitre.org

Chapter G.67

Mr. Dean F. Lamiano is a Principal Communications Engineer and Associate Program Manager at MITRE's Center for Advanced Aviation System Development (CAASD), engaged in the research and system engineering for air traffic control communications systems. Dean is a member of IEEE and has a BS in Electrical Engineering from the SUNY at Buffalo, and an MSEE from the Johns Hopkins University.

Steven J. Landry

Purdue University
School of Industrial Engineering
West Lafayette, IN, USA
slandry@purdue.edu

Chapter G.68

Steven J. Landry is an Assistant Professor in the School of Industrial Engineering at Purdue University. He received his MS in Aeronautics and Astronautics from MIT, and his PhD in Industrial and Systems Engineering from Georgia Tech. He has over 2500 heavy jet flight hours as a USAF C-141B pilot. His research interests are in aviation systems engineering and human factors.

John D. Lee

University of Iowa
Department Mechanical and Industrial
Engineering, Human Factors Research
National Advanced Driving Simulator
Iowa City, IA, USA
jdlee@engineering.uiowa.edu

Chapter C.25

John D. Lee graduated with degrees in psychology and mechanical engineering from Lehigh University and owns a PhD in mechanical engineering from the University of Illinois. He is a Professor in the Department of Mechanical and Industrial Engineering at the University of Iowa. His research focuses on the safety and acceptance of human-machine systems by considering how technology mediates attention.

Tae-Eog Lee

KAIST
Department of Industrial and Systems
Engineering
Daejeon, Korea
telee@kaist.ac.kr

Chapter F.52

Tae-Eog Lee is Professor in the Department of Industrial and Systems Engineering and Director of the Center for Modeling and Simulation Technology Research at KAIST. His interests include automated equipment scheduling and control and software engineering for semiconductor manufacturing, and discrete event system modelling and control. He graduated from Seoul National University (KAIST) and Ohio State University.

Wing B. Lee

The Hong Kong Polytechnic University
Industrial and Systems Engineering
Kowloon, Hong Kong
wb.lee@polyu.edu.hk

Chapter F.49

W.B. Lee received his Master of Technology from Brunel University in 1976 and the Doctorate from the University of Hong Kong in 1986. He is the Cheng Yick-chi Chair Professor of Manufacturing Engineering, the Director of The Advanced Technology Manufacturing Research Centre as well as the Knowledge Management Research Centre of The Hong Kong Polytechnic. His research interests include advanced manufacturing technology, materials processing and knowledge management.

Mark R. Lehto

Purdue University
School of Industrial Engineering
West Lafayette, IN, USA
lehto@purdue.edu

Chapter D.39

Dr. Mark R. Lehto is an Associate Professor in the School of Industrial Engineering at Purdue University, where he is Co-chair of the Interdisciplinary Graduate Program in Human Factors. Dr. Lehto's research and teaching interests are in the areas of hazard communication and decision support. He is particularly interested in methods of increasing the effectiveness of information provided to consumers and workers.

Kauko Leiviskä

University of Oulu
Control Engineering Laboratory
Oulun Yliopisto, Finland
kauko.leiviska@oulu.fi

Chapter D.36

Kauko Leiviskä received a Diploma degree in Engineering in Process Engineering in 1975 and the Doctor of Technology in Control Engineering in 1982, both from University of Oulu. He is Professor of Control Engineering and Dean of Faculty of Technology. His research interests are in applications of soft computing methods. He is (co)author of more than 200 publications.

Mary F. Lesch

Liberty Mutual Research Institute
for Safety
Center for Behavioral Sciences
Hopkinton, MA, USA
mary.lesch@libertymutual.com

Chapter D.39

Mary F. Lesch holds a PhD in cognitive psychology from the University of Massachusetts – Amherst. She completed post-doctoral training in neuropsychology at Rice University in 1999. Since then, she has been a Research Scientist at the Liberty Mutual Research Institute for Safety where her research focuses on risk perception and communication. Recent research has investigated age-related effects on warning symbol comprehension.

Jianming Lian

Purdue University
School of Electrical and Computer
Engineering
West Lafayette, IN, USA
jlian@purdue.edu

Chapter B.11

Jianming Lian received the BS degree from University of Science and Technology of China in 2004. Then he attended Purdue University, West Lafayette, IN USA for his graduate study, where he received the MS degree in 2007. He is now a PhD candidate in the School of Electrical and Computer Engineering in the area of Automatic Control. His research interests include nonlinear control, adaptive control and switched systems.

Lin Lin

Waseda University
Information, Production & Systems
Research Center
Kitakyushu, Japan
linlin@aoni.waseda.jp

Chapter C.29

Lin Lin received ME and PhD degrees in Engineering from Waseda University in 2006 and 2008, respectively. He was Research Assistant at Graduate School of Information, Production and Systems, Waseda University 2007–2009. His research interests are genetic and evolutionary computation and applications to network design and optimization for manufacturing scheduling and logistics systems. He has published *Network Models and Optimization* together with Dr. M. Gen and Dr. R. Cheng.

Laurent Linxe

Peugeot SA
Hagondang, France
laurent.linxe@mpsa.com

Chapter D.35

Laurent Linxe graduated as a multi-disciplinary engineer from Centrale Lille in 1991, joined Peugeot SA in 1992 and PCI-SCEMM in 2005. As the manager of the Machining Systems PCI, he initiated relationships with the Industrial Engineering and Computer Science of Saint-Etienne and M. Dolgui. Since 2008, he has been in charge of the Manufacturing Department for 2.0 and 2.2 litre of HDI Common Rail Diesel Engines, Peugeot SA Tremery Plant in Lorraine Eastern France.

T. Joseph Lui

Whirlpool Corporation
Global Product Organization
Benton Harbor, MI, USA
t_joseph_lui@whirlpool.com

Chapter I.83

T. Joseph Lui received a BS from Virginia Tech, a MS in Electrical Engineering from the Illinois Institute of Technology and a MBA from the University of Chicago. He is currently holding a director position at Whirlpool for global connectivity, controls and electronics. Prior to joining Whirlpool, Mr. Lui held various leadership and management positions at Motorola developing and marketing wireless technologies and products.

Wolfgang Mann

Chapter E.46

Profactor Research and Solutions GmbH
Process Design and Automation,
Forschungszentrum
Seibersdorf, Austria
wolfgang.mann@profactor.at

Wolfgang Mann received the MS from Vienna University of Technology in Mechanical Engineering. He is currently Head of the Department Prozess Design and Automation. His research interests are mainly lot size one automation solutions in modern test stands, handling of small and complex parts, ultra precision assembly, vision, and sensor guided assembly.

Sebastian V. Massimini

Chapter G.67

The MITRE Corporation
McLean, VA, USA
svm@mitre.org

Dr. Sebastian Vince Massimini is currently a Senior Principal Engineer at MITRE's Center for Advanced Aviation System Development, in McLean, Virginia, where he is a research analyst in navigation and surveillance for airports and air traffic control architecture. Dr. Massimini is an associate fellow of the American Institute of Aeronautics and Astronautics (AIAA). He received his Doctor of Science in Operations Research from The George Washington University.

Francisco P. Maturana

Chapter C.28

University/Company Rockwell Automation
Department Advanced Technology
Mayfield Heights, OH, USA
fpmaturana@ra.rockwell.com

Dr. Maturana is a Principal Research Engineer at Rockwell Automation. His research interests are in autonomous control and self organizing systems for automation, distributed computing, and high performance simulations. He has been issued 16 US/European patents in agent technology and a technical committee member for IEEE SMC/ISM, BASYS, HOLOMAS. Dr. Maturana received his PhD in Intelligent Manufacturing Systems from The University of Calgary, Canada.

Henry Mirsky

Chapter H.75

University of California, Santa Barbara
Department of Chemical Engineering
Santa Barbara, CA, USA
Mirsky@lifesci.ucsb.edu

Henry Mirsky is a doctoral candidate in the Program in Biomolecular Science and Engineering at the University of California, Santa Barbara. He holds a BS degree in Materials Science from Cornell University and a BS in Molecular and Cell Biology from the University of Arizona. His research interests include biochemical modelling, sensitivity analysis, and circadian biology.

Sudip Misra

Chapter B.12

Indian Institute of Technology
School of Information Technology
Kharagpur, India
sudip_misra@yahoo.com

Dr. Sudip Misra is an Assistant Professor in the School of Information Technology at the Indian Institute of Technology Kharagpur, India. He received his PhD in Computer Science from Carleton University, Ottawa, Canada. His current research interests include algorithm design and soft computing applications in telecommunications. Dr. Misra is the author of several research papers.

Satish C. Mohleji

Chapter G.67

Center for Advanced Aviation System
Development (CAASD)
The MITRE Corporation
McLean, VA, USA
smohleji@mitre.org

Satish Mohleji is a Senior Principal Engineer in the Center for Advanced Aviation System Development (CAASD) of the MITRE Corp. For 38 years, he has worked on designing and analyzing future operational concepts for enhancing Air Traffic Management systems at US and International airports. He received a PhD from the University of Windsor, Ontario, and MS in Management Science from the American University in Washington D.C. He is an Associate Fellow of the AIAA.

Gérard Morel

Chapter E.42

Centre de Recherche en Automatique
Nancy (CRAN)
Vandoeuvre, France
gerard.morel@cran.uhp-nancy.fr

Gérard Morel is Professor at Nancy University and Vice-Director of CRAN. He published over 150 articles on systems and automation engineering. He served in positions at IFAC and with the European Commission. He is Europe editor of the IJIM and associate editor of the IFAC International Journal on Engineering Applications of Artificial Intelligence.

René J. Moreno Masey

Chapter F.60

University of Sheffield
Automatic Control and Systems
Engineering
Sheffield, UK
cop07rjm@sheffield.ac.uk

René J. Moreno Masey received an MEng in Mechanical Engineering from the University of Manchester (1996) and an MSc in Robotics and Automation from the University of Salford (2006). He worked for Unilever (1997–2001) designing hygienic food production lines. His current PhD research at the University of Sheffield and IIT, Genoa involves the design of a low-cost industrial robot for the food industry.

Clayton Munk

Chapter F.51

Boeing Commercial Airplanes
Material & Process Technology
Seattle, WA, USA
clayton.l.munk@boeing.com

Clayton Munk received the Masters of Technology Management from Brigham Young University in 2006. He is currently a Technical Fellow and has over 21 years experience in advanced assembly methods for aircraft structure within M&PT at Boeing Commercial Airplanes. He is a member of the SAE Aerospace, Air and Space Group and is also the Chairman of the SAE Aerospace Automated Fastening Committee.

Yuko J. Nakanishi

Chapter G.66

Nakanishi Research and Consulting, LLC
New York, NY, USA
nakanishi@transresearch.net

Dr. Yuko J. Nakanishi is Principal, Nakanishi Research and Consulting, LLC; Vice President of Intelligent Transportation Society NY and Chair of the TRB Subcommittee on Training, Education, and Technology Transfer. Her expertise includes ITS, security, and performance assessment. She holds a PhD in Transportation Planning and Engineering from Polytechnic Institute of NY University, MS in Civil Engineering from City College NY, and MBA in Management from Columbia University.

Dana S. Nau

Chapter B.14

University of Maryland
Department of Computer Science
College Park, MD, USA
nau@cs.umd.edu

Dr. Nau is a Professor of both Computer Science and Systems Research at the University of Maryland, and co-directs the Laboratory for Computational Cultural Dynamics. He has more than 300 publications and is co-author of a comprehensive textbook on automated planning. He has authored award-winning software, including the SHOP2 planning system which is used in projects worldwide. He is a Fellow of the Association for the Advancement of Artificial Intelligence (AAAI).

Peter Neumann

Chapter F.56

Institut für Automation
und Kommunikation
Magdeburg, Germany
peter.neumann@ifak.eu

Peter Neumann received the PhD in 1967. Peter Neumann was full professor at the Otto-von-Guericke-University Magdeburg from 1981 to 1994. In 1991 he founded the applied research institute “ifak” (Institut für Automation and Kommunikation) headed by him until 2004. His interests are industrial communications, device management and formal methods in engineering of distributed computer control systems.

Shimon Y. Nof

Purdue University
PRISM Center and School of Industrial Engineering
West Lafayette, IN, USA
nof@purdue.edu

Chapters A.3, C.30, I.88

Shimon Y. Nof is Professor of Industrial Engineering at Purdue University since 1977. He is Director of the NSF-industry supported PRISM Center, President of IFPR and Fellow of the IIE. Nof is the author/editor of ten books. His main research is concerned with automated collaboration, systems security, integrity, and assurance; integrated production and service operations with decentralized decision support networks; and collaborative robotics, e-Work, and e-Service.

Anibal Ollero

Universidad de Sevilla
Departamento de Ingeniería de Sistemas y Automática
Sevilla, Spain
aollero@cartuja.us.es

Chapter B.16

Anibal Ollero is full Professor at the University of Seville and Scientific Director of the Center for Advanced Aerospace Technologies (FADA-CATEC). He is the author of more than 375 publications including 5 books, and led or participated in more than 90 projects, including 17 projects funded by the European Commission. He is the recipient of 9 national and international awards.

John Oommen

Carleton University
School of Computer Science
Ottawa, Canada
oommen@scs.carleton.ca

Chapter B.12

Dr. John Oommen is a Chancellor's Professor at Carleton University in Ottawa, Canada. He obtained his B. Tech. from IIT Madras, India (1975), his MS from IISc in Bangalore, India (1977), and his PhD from Purdue University, West Lafayette (1982). He is an IEEE and IAPR Fellow. He is also an Adjunct Professor with the University of Agder in Grimstad, Norway.

Robert S. Parker

University of Pittsburgh
Department of Chemical and Petroleum Engineering
Pittsburgh, PA, USA
rparker@pitt.edu

Chapter H.76

Robert S. Parker is an Associate Professor of Chemical and Petroleum Engineering at the University of Pittsburgh. Bob received his chemical engineering degrees from the University of Rochester (BS 1994) and the University of Delaware (PhD 1999). His research interests include the development of mathematical models of disease (e.g., cancer, diabetes, and inflammation) and the synthesis of model-based treatment design algorithms.

Alessandro Pasetti

P&P Software GmbH
Tägerwilen, Switzerland
pasetti@pnp-software.com

Chapter C.22

Alessandro Pasetti holds degrees in Electrical Engineering (University of Trieste, 1986), Control Engineering (Imperial College, 1987), and Sociology (University of Cambridge, 1997), and a doctorate in Software Engineering (University of Konstanz, 2002). He worked as a Control Engineer for the ESA, and currently works for P&P Software GmbH. His research interests are in the field of software reuse technologies for embedded systems. He is the author of the book *Software Frameworks and Embedded Control Systems*.

Anatol Pashkevich

Ecole des Mines de Nantes
Department of Automatic Control and Production Systems
Nantes, France
anatol.pashkevich@emn.fr

Chapter F.59

Anatol Pashkevich received his degree in Electrical Engineering (1977) and PhD in Control and Robotics (1982), both from Minsk Radio Engineering Institute, Belarus. Since 1987 he served as head of the Robotic Laboratory at Belarusian State University of Informatics and Radio Electronics. Currently he is head of the Department of Automatic Control and Production Systems at Ecole des Mines de Nantes, France. His research interests include robotics, manufacturing automation and computer-aided design. He is a Member of the TC Manufacturing Plant Control of IFAC.

Bozenna Pasik-Duncan

University of Kansas
Department of Mathematics
Lawrence, KS, USA
bozenna@math.ku.edu

Chapter E.44

Bozenna Pasik-Duncan received her PhD and Habilitation degrees in Mathematics from the Warsaw School of Economics in 1978 and 1986, respectively. She is a Professor of Mathematics, and Courtesy Professor of EECS at the University of Kansas. Her research interests are primarily in stochastic adaptive control and science, engineering and mathematics education. Dr. Pasik-Duncan is an IEEE Fellow and Distinguished Member of the IEEE CSS. She is the chair of the IEEE CSS, AACC and IFAC and the chair of the IFAC Harold Chestnut Control Engineering Textbook Prize Selection Committee.

Peter C. Patton

Oklahoma Christian University
School of Engineering
Oklahoma City, OK, USA
peter.patton@oc.edu

Chapters B.18, E.45

Peter C. Patton has taught computer science, mathematics, aerospace engineering, and ancient history, classical civilizations at the Universities of Kansas, Minnesota, Stuttgart, and Pennsylvania. His last book, Design for Trustworthy Software (together with Bijay Jayaswal) won the Crosby Medal from the ASQ. He is currently teaching mechanical engineering, Western Civilization, and Philosophy to engineering students at Oklahoma Christian University.

Richard D. Patton

Lawson Software
St. Paul, MN, USA
richard.patton@lawson.com

Chapter B.18

Richard D. Patton is Chief Technology Officer of Lawson Software and has been involved with building business application software languages and development methodologies for over 25 years. His current project is building a new application development language based on the latest research in the areas of pattern languages and complex adaptive systems theory as well as Charles Sanders Peirce's triadic semiotics.

Carlos E. Pereira

Federal University of Rio Grande do Sul (UFRGS)
Department Electrical Engineering
Porto Alegre RS, Brazil
cpereira@ece.ufrgs.br

Chapter F.56

Carlos Eduardo Pereira received the Dr.-Ing. degree from the University of Stuttgart, Germany (1995), the MSc in Computer Science (1990) and the BS degrees in Electrical Engineering (1987) both from the Federal University of Rio Grande do Sul (UFRGS)in Brazil. He is an Associate Electrical Engineering Professor at UFRGS and Technical Director of the CETA Applied Research Center. His research focuses on methodologies and tool support for the development of distributed real-time embedded systems, with special emphasis on industrial automation applications. He is Chair of the IFAC Technical Committee on Manufacturing Plant Control (TC 5.1).

Jean-François Pétin

Centre de Recherche en Automatique
de Nancy (CRAN)
Vandoeuvre, France
jean-francois.petin@cran.uhp-nancy.fr

Chapter E.42

Jean-François Pétin is Assistant Professor at Nancy University as researcher at CRAN and as a teacher at ESIAL. His research topic deals with formal automation engineering. He is currently working on combining formal discrete events models with system engineering approaches for improving safety and reconfigurability of control systems. He is member of the IFAC Technical Committee 5.1. Manufacturing Plant Control.

Chandler A. Phillips

Wright State University
Department of Biomedical, Industrial and Human Factors Engineering
Dayton, OH, USA
Chandler.Phillips@wright.edu

Chapter B.17

Dr. C.A. Phillips received his MD degree (1969) from the University of Southern California and is currently the Brage Golding Distinguished Professor of Research and Director of the Ergonomic Engineering program. His research interests include neuromuscular and sensory feedback systems for human operator control, biomimetic modeling of pneumatic muscle actuators, and quantitative modeling of human operator and machine interaction.

Friedrich Pinnekamp

Chapters D.32, D.33

ABB Asea Brown Boveri Ltd.
Corporate Strategy
Zurich, Switzerland
friedrich.pinnekamp@ch.abb.com

Friedrich Pinnekamp (PhD in physics) is member of the Senior Management at ABB Asea Brown Boveri Ltd. As assistant to all the chief technology officers of ABB in the last 28 years, he helped to set up the ABB global R&D organization, installing research centres and programs for all core competences required as well as being responsible for ABB Review, the technology magazine of the group. Friedrich is Vice President of the European Industrial Research Management Association (EIRMA).

Daniel J. Power

Chapter I.87

University of Northern Iowa
College of Business Administration
Cedar Falls, IA, USA
daniel.power@uni.edu

Daniel J. "Dan" Power is a Professor of Information Systems and Management at the College of Business Administration at the University of Northern Iowa, Cedar Falls, Iowa and the editor of DSSResources.com, a web-based knowledge repository about computerized systems that support decision making. Also, Dan is the Decision Support Expert at the Business Intelligence Network. In 1982, Professor Power received a PhD in Business Administration from the University of Wisconsin-Madison.

Damien Poyard

Chapter D.35

PCI/SCEMM
Saint-Etienne, France
damien.poyard@pci.fr

Damien Poyard graduated as a Mechanical Engineer from ECAM Lyon in 1989 and holds a DEA in Industrial Automatism from INSA Lyon University (1989). He is working since 1990 in PCI/SCEMM, a subsidiary of PSA Group Automotive Company, dedicated to the design and production of machining lines. PCI realises transfer lines or flexible lines including high-speed machining centres (HSMC).

Srinivasan Ramaswamy

Chapter E.47

University of Arkansas at Little Rock
Department of Computer Science
Little Rock, AR, USA
srini@ieee.org

Dr. Ramaswamy's research interests are on intelligent control, modeling, analysis and simulation, stability and scalability of complex systems. His work is motivated by the desire to understand the various requirements to build scalable, intelligent software systems. He is a senior member of IEEE and ACM, and a member of the Society for Computer Simulation International, Computing Professionals for Social Responsibility.

Piercarlo Ravazzi

Chapter A.6

Politecnico di Torino
Department Manufacturing Systems
and Economics
Torino, Italy
piercarlo.ravazzi@polito.it

Piercarlo Ravazzi received the Laurea degree in Economics from the University of Rome in 1974. He is currently Full Professor of Economics at the Polytechnic University of Torino. His research interests include production economics, macroeconomic theory and Italian economy, managerial finance and economics of telecommunications. He has authored several books on these topics.

Daniel W. Repperger

Chapter B.17

Wright Patterson Air Force Base
Air Force Research Laboratory
Dayton, OH, USA
Daniel.repperger@wpafb.af.mil

D.W. Repperger received his BS, MS, and PhD degrees in Electrical Engineering from Rensselaer Polytechnic Institute and Purdue University. At the Air Force Research Laboratory his research has been focused on human–machine systems, control theory and biomedical engineering. He is a Fellow of the IEEE, AIMBE, AsMA, The Air Force Research Laboratory, and the Ohio Academy of Science.

William Richmond

Western Carolina University
Accounting, Finance, Information Systems
and Economics
Cullowhee, NC, USA
brichmond@email.wcu.eud

Chapter I.91

William Richmond is an Associate Professor of Computer Information Systems. His research focuses on the economics of information with application to the financial services industry. He received his PhD from Purdue University in 1988.

Dieter Rombach

University of Kaiserslautern
Department of Computer Science,
Fraunhofer Institute for Experimental
Software Engineering
Kaiserslautern, Germany
rombach@iese.fraunhofer.de

Chapter I.92

Dr. H. Dieter Rombach is a Full Professor in the Department of Computer Science at the University of Kaiserslautern, Germany. He holds a chair in software engineering, is executive and founding Director of the Fraunhofer Institute for Experimental Software Engineering (IESE), and chairs the Fraunhofer ICT Group. His research interests are in software methodologies, modelling and measurement of the software process and resulting products, software reuse, and distributed systems. Results are documented in more than 180 publications in international journals and conference proceedings.

Shinsuke Sakakibara

Fanuc Ltd.
Yamanashi, Japan
sakaki@i-dreamer.co.jp

Chapter C.21

Shinsuke Sakakibara graduated from Applied Physics Department of the University of Tokyo in 1972. He joined Fanuc Ltd. in 1972 and received his doctoral degree in engineering from the University of Tokyo in 1995. He assumed the position of Chairman of the Robotics Society of Japan in 2009.

Timothy I. Salsbury

Johnson Controls, Inc.
Building Efficiency Research Group
Milwaukee, WI, USA
tim.salsbury@gmail.com

Chapter G.62

Dr. Salsbury has a PhD from Loughborough University with graduate research also performed at Oxford University and MIT. Previous positions include a Research Scientist at VTT Finland and Research Fellow at BNL. Dr Salsbury is currently a Principal Researcher at Johnson Controls with research interests in control performance assessment, fault detection, adaptive control, optimization, and statistical data analysis.

Branko Sarh

The Boeing Company – Phantom Works
Huntington Beach, CA, USA
branko.sarh@boeing.com

Chapter F.51

Dr. Branko Sarh is a Technical Fellow specializing in the development of advanced assembly systems and processes at Boeing Phantom Works in Huntington Beach. He received his Masters in Aeronautical Engineering from the University of Aachen, and his PhD in Mechanical Engineering from the University of Hamburg, Germany. His 40 years of technical and international manufacturing experience include project management assignments at MBB, Airbus, Rohr, McDonnell Douglas and Boeing.

Sharath Sasidharan

Marshall University
Department of Management
and Marketing
Huntington, WV, USA
sasidharan@marshall.edu

Chapter I.89

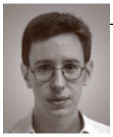
Dr. Sasidharan is an Assistant Professor in the Lewis College of Business at Marshall University. He holds a PhD in Decision Science and Information Systems from the University of Kentucky. His research interests include human–computer interaction, technology acceptance, ERP systems, and e-Commerce. He has published in several academic journals.

Brandon Savage

Chapter H.77

GE Healthcare IT
Chalfont St Giles, UK
Brandon.Savage@med.ge.com

Brandon Savage, MD, Chief Medical Officer of GE Healthcare IT, is responsible for driving General Electric's clinical IT vision, where his prime focus is to empower the highest level of care for any institution with the use of technology. Dr. Savage received his MD from University of California at San Diego and has been publishing in numerous periodicals and medical journals.



Manuel Scavarda Basaldúa

Chapter F.54

Kimberly Clark
Buenos Aires, Argentina
manuel.scavarda@kcc.com

Manuel Scavarda Basaldúa graduated as an Industrial Engineer at ITBA – Instituto Tecnológico de Buenos Aires. He obtained a MSc degree in Industrial Engineering from Chalmers University of Technology, Stockholm, Sweden. He worked as an Operations Analyst for the Stena Metall Group in Sweden and Norway and then joined Kimberly-Clark. Currently, he performs as Supply Chain Development Manager at KC River Plate Region.

Walter Schaufelberger (△)

ETH Zurich
Institute of Automatic Control
Zurich, Switzerland

Chapter C.22

Professor Walter Schaufelberger (1940–2008) was Full Professor at the Institute of Automatic Control, ETH Zurich. He studied Electrical Engineering at the ETH Zurich where he earned a doctorate. His main interests were in theoretical treatment of problems relevant to practice and to computer applications. The development of user friendly software played a major role in his activities. He was the Spokesman for "Integration of Complex Systems" of the European Science Foundation. He was Fellow of IFAC, SEFI, and the European Society for Engineering.

Bobbie D. Seppelt

The University of Iowa
Mechanical and Industrial Engineering
Iowa City, IA, USA
bseppelt@engineering.uiowa.edu

Chapter C.25

Bobbie D. Seppelt graduated with her MS degree in Engineering Psychology from The University of Illinois in 2003. She is currently a graduate research assistant in the Industrial Engineering PhD program at The University of Iowa. Her research interests include interface design and driver support, automation reliance and supervisory control, application of ecological frameworks to interface design, and trust in automation.

Ramesh Sharda

Chapter I.87

Oklahoma State University
Spears School of Business
Stillwater, OK, USA
Ramesh.sharda@okstate.edu

Dr. Ramesh Sharda is Director of the Institute for Research in Information Systems, ConocoPhillips Chair of Management of Technology, and a Regents Professor of Management Science and Information Systems in the Spears School of Business at Oklahoma State University. His research interests are in decision support systems, neural network applications, and technologies for managing information overload. Defense Ammunitions Center, NSF, and other organizations have funded his research.

Keiichi Shirase

Chapter F.48

Kobe University
Department of Mechanical Engineering
Kobe, Japan
shirase@mech.kobe-u.ac.jp

Keiichi Shirase received the MS degree from Kobe University, and joined Kanazawa University as a Research Associate in 1984. He received the Dr. Eng. from Kobe University in 1989. He was an Associate Professor in 1995 at Kanazawa University, and in 1996 at Osaka University. Since 2003, he has been a Professor at Kobe University. His research interests are mainly in autonomous machine tool and intelligent CAD/CAM systems.

Jason E. Shoemaker

University of California
Department of Chemical Engineering
Santa Barbara, CA, USA
jshoe@engr.ucsb.edu

Chapter H.75

Jason E. Shoemaker graduated from the University of California, Santa Barbara with a doctorate in Chemical Engineering. His research studies include drug target identification, the design and control of biological networks and their implications on communications networks. Shoemaker is a member of UC, IGERT and JST.

Moshe Shoham

Technion – Israel Institute
of Technology
Department of Mechanical Engineering
Haifa, Israel
shoham@technion.ac.il

Chapter H.78

Professor Moshe Shoham has been conducting research in robotics with a special focus on new robot structures and medical applications. He has been heading the Robotics Laboratories of the Mechanical Engineering Department at Columbia University, New York, and at the Technion-Israel Institute of Technologies. In 2001 he founded Mazor Surgical Technologies – a company that produces a miniature robot for spine surgery.

Marwan A. Simaan

University of Central Florida
School of Electrical Engineering
and Computer Science
Orlando, FL, USA
simaan@mail.ucf.edu

Chapter H.79

Marwan A. Simaan is Distinguished Professor of Electrical Engineering and Computer Science at the University of Central Florida. He received the PhD degree from the University of Illinois at Urbana-Champaign and served on the Electrical Engineering faculty at the University of Pittsburgh. He is a member of the US National Academy of Engineering and a fellow of IEEE, AAAS and ASEE. His research interests are in control and signal processing with applications to biomedical devices.

Johannes A. Soons

National Institute of Standards
and Technology
Manufacturing Engineering Laboratory
Gaithersburg, MD, USA
soons@nist.gov

Chapter A.7

Johannes A. Soons leads the Manufacturing Process Metrology Group of the Manufacturing Engineering Laboratory at the National Institute of Standards and Technology. He received his PhD at the Eindhoven University of Technology in the Netherlands. His research interests include machining processes, machine tool metrology, and optics fabrication and testing.

Dieter Spath

Fraunhofer-Institute for Industrial
Engineering IAO
Stuttgart, Germany
dieter.spath@iao.fraunhofer.de

Chapter D.34

Professor Dieter Spath studied mechanical engineering at the Technical University of Munich where he also earned his doctor's degree in 1981. He was Manager in KASTO-enterprises and Professor at the University Karlsruhe (TH). Since 2002 he is Professor at the University of Stuttgart and Head of the Institute for Human Factors and Technology Management (IAT) and the Fraunhofer Institute for Industrial Engineering (IAO). He holds a Honorary doctorate from the TU Munich and received the Cross of the Order of Merit of the Federal Republic of Germany.

Harald Staab

ABB AG, Corporate Research Center
Germany
Robotics and Manufacturing
Ladenburg, Germany
harald.staab@de.abb.com

Chapter I.84

Dr. Harald Staab graduated from the Technical University of Darmstadt in Electrical Engineering in 2001. From 2002 to 2007 he was with the Fraunhofer Institute of Manufacturing Engineering and Automation IPA, Stuttgart, Germany. He earned his PhD in driving dynamics of mobile robots from Stuttgart University in 2009. Since 2008 he is with ABB AG, in the Corporate Research Centre, Ladenburg, Germany.

Petra Steffens

Fraunhofer Institute for Experimental Software Engineering
Department Business Area e-Government
Kaiserslautern, Germany
petra.steffens@iese.fraunhofer.de

Chapter I.92

Petra Steffens is manager of the business area e-Government at the Fraunhofer Institute for Experimental Software Engineering, Kaiserslautern, Germany. Her research interests include the design of e-Government strategies on all governmental levels, engineering of process chains, and the development of e-Government solutions. She holds a MS in Computer Science (University of Bonn) and a M. Phil. in Linguistics (University of Exeter).

Jörg Stelling

ETH Zurich
Department of Biosystems Science and Engineering
Basel, Switzerland
joerg.stelling@bsse.ethz.ch

Chapter H.75

Jörg Stelling received a MS degree in Biotechnology, University of Braunschweig and a PhD in Control and Dynamic Systems, University of Stuttgart in 1996 and 2004, respectively. He is currently an Associate Professor at ETH Zurich. His research interests include methods and model development for complex biological systems, including systems identification, model discrimination, and systems design.

Raúl Suárez

Technical University of Catalonia (UPC)
Institute of Industrial and Control Engineering (IOC)
Barcelona, Spain
raul.suarez@upc.edu

Chapter C.27

Raúl Suárez (Electronic Engineer, National University of San Juan, Argentina, 1984; PhD, Technical University of Catalonia, Barcelona, Spain, 1993) is researcher in the Institute of Industrial and Control Engineering of the Technical University of Catalonia, where he currently serves as Deputy Director (from 2003). His research interests include grasping, manipulation, assembly, task planning, telemanipulation and manufacturing automation.

Kinnya Tamaki

Aoyama Gakuin University
School of Business Administration
Tokyo, Japan
ytamaki@a2en.aoyama.ac.jp

Chapter I.85

Kinnya Tamaki received the PhD from Waseda University, School of Science and Engineering in 1989. He is Professor in the School of Business Administration, Aoyama Gakuin University. He currently serves as the Director of the Research Center for e-Learning Professional Competency. His research interests are mainly in human resource development for e-Learning professionals and innovative-business strategy.

Jose M.A. Tanchoco

Purdue University
School of Industrial Engineering
West Lafayette, IN, USA
tanchoco@purdue.edu

Chapter F.55

Jose M.A. Tanchoco received the MSIE and PhD degrees from Purdue University where he is Professor of Industrial Engineering. His research interests are in enterprise operations and production systems, global logistics, automated guided vehicle systems (AGVS), unit load design, and manufacturing and industrial economics. He was an early pioneer on AGVS design and operations.

Stephanie R. Taylor

Department of Computer Science
Waterville, ME, USA
srtaylor@colby.edu

Chapter H.75

Stephanie R. Taylor (PhD 2008, University of California Santa Barbara) is Clare Boothe Luce Assistant Professor of Computer Science at Colby College in Waterville, ME. Her research interests include mathematical modelling of biological systems, model order reduction, and dynamical systems.

Peter Terwiesch

ABB Ltd.
Zurich, Switzerland
peter.terwiesch@ch.abb.com

Chapter A.8

Peter Terwiesch is Chief Technology Officer of ABB Ltd. Prior to his current appointment he was president of ABB Automation Ltd, Germany, and global head of technology for ABB Automation. Peter holds a PhD from ETH Zurich, Switzerland, and an MSc in Electrical Engineering from Karlsruhe Institute of Technology, Germany.

Jocelyne Troccaz

CNRS – Grenoble University
Computer Aided Medical Intervention –
TIMC laboratory, IN3S – School
of Medicine – Domaine de la Merci
La Tronche, France
jocelyne.troccaz@imag.fr

Chapter H.82

Graduated in Computer Science, Jocelyne Troccaz received her PhD in Robotics in 1986 from the Institut National Polytechnique de Grenoble. She is a Research Director at CNRS and in charge of a team involved in Computer Aided Medical Intervention. Her research interests include medical robotics and medical imaging.

Edward Tunstel

Johns Hopkins University
Applied Physics Laboratory, Space
Department
Laurel, MD, USA
Edward.Tunstel@jhuapl.edu

Chapter G.69

Edward Tunstel received the ME degree at Howard University and PhD in Electrical Engineering at University of New Mexico. After 18 years at the NASA JPL he joined the Johns Hopkins University Applied Physics Laboratory in 2007 leading robotics development for space missions. His research interests include space robotics and soft computing for autonomous control. He is a Senior Member of IEEE and Vice President for IEEE SMCS (2008–2009).

Tibor Vámos

Hungarian Academy of Sciences
Computer and Automation Institute
Budapest, Hungary
vamos@sztaki.hu

Chapter A.5

Tibor Vámos graduated from the Budapest Technical University in 1949. Since 1986 he is Chairman of the Board, Computer and Automation Research Institute of the Hungarian Academy of Sciences, Budapest. He was President of IFAC 1981–1984 and is a Fellow of the IEEE, ECCAI, IFAC. Professor Vamos is Honorary President of the John v. Neumann Society and won the State Prize of Hungary in 1983. His main fields of interest cover large-scale systems in process control, robot vision, pattern recognition, knowledge-based systems, and epistemic problems. He is author and co-author of several books and about 160 papers.

István Vajk

Budapest University of Technology
and Economics
Department of Automation and Applied
Informatics
Budapest, Hungary
vajk@aut.bme.hu

Chapter B.10

István Vajk graduated as an Electrical Engineer and obtained his PhD degree in 1977 from the Budapest University of Technology and Economics, Hungary. Since 1994 he has been the Head of Department of Automation and Applied Informatics at the same university. His main interest covers the theory and application of control systems, especially adaptive systems and system identification, as well as applied informatics.

Gyula Vastag

Corvinus University of Budapest
Institute of Information Technology,
Department of Computer Science
Budapest, Hungary
gyula.vastag@uni-corvinus.hu

Chapter G.73

Gyula Vastag received MSc and PhD degrees from Corvinus University of Budapest. Prior to returning to his alma mater, he spent almost two decades with US business schools. He is Founding Member and past Associate Director of the Global Manufacturing Research Group and is active in the International Society for Inventory Research. He co-edited the book *Global Manufacturing Practices*.

Juan D. Velásquez

Purdue University
PRISM Center and School of Industrial Engineering
West Lafayette, IN, USA
jvelasqu@purdue.edu

Chapters I.88, J.94

Juan Diego Velásquez is a PhD candidate in the School of Industrial Engineering at Purdue University. He received his MSIE and BSIE degrees from Purdue. He is a Senior Researcher at the PRISM Center and an Assessment and Evaluation Specialist at the Center for Instructional Excellence. His research interests include protocol definition, scheduling algorithms, decision support systems and organizational learning methods.

Matthew Verleger

Purdue University
Engineering Education
West Lafayette, IN, USA
matthew@mverleger.com

Chapter E.44

Matthew Verleger is a graduate of Purdue University's School of Engineering Education and is currently doing post-doctoral research with his PhD advisor. His research focus is on how students learn to develop mathematical models and how those models can be translated into discipline-specific skills. He also researches technology-assisted pedagogies, particularly the use of online learning modules.

François B. Vernadat

Université Paul Verlaine Metz
Laboratoire de Génie Industriel
et Productique de Metz (LGIPM)
Metz, France
Francois.Vernadat@eca.europa.eu

Chapter I.86

François B. Vernadat received the PhD in Electrical Engineering and Automatic Control from University of Clermont, France, in 1981. He has been a research officer at the National Research Council of Canada in the 1980s and at the Institut National de Recherche en Informatique et Automatique in France in the 1990s. He joined the University of Metz in 1995 as a full professor and founded the LGIPM research laboratory. His research interests include enterprise modeling, enterprise architectures, enterprise integration and interoperability. He is a member of IEEE and ACM.

Agostino Villa

Politecnico di Torino
Department Manufacturing Systems and Economics
Torino, Italy
agostino.villa@polito.it

Chapter A.6

Agostino Villa is Full Professor of Production Systems and Technologies and Professor of Production Planning and Control at the Politecnico di Torino, Italy. He is currently also Director of the University's Evaluation Committee. His research interests include modelling and management of production systems and enterprise networks, as well as transferability of industrial management methods in human-centred systems. He is Past-president and Fellow of IFPR, member of IFAC and IFPR TCs.

Birgit Vogel-Heuser

University of Kassel
Faculty of Electrical Engineering/ Computer Science, Department Chair of Embedded Systems
Kassel, Germany
vogel-heuser@uni-kassel.de

Chapter F.58

Birgit Vogel-Heuser graduated in Electrical Engineering and obtained her PhD in Mechanical Engineering from the RWTH Aachen in 1991. She worked nearly ten years in industrial automation for machine and plant manufacturing industry. She is now head of the Chair of Embedded Systems at the University of Kassel. Her research work is focussed on improvement of efficiency in automation engineering for hybrid process and heterogeneous distributed embedded systems.

Edward F. Watson

Louisiana State University
Information Systems and Decision Sciences
Baton Rouge, LA, USA
ewatson@lsu.edu

Chapter I.90

Edward F. Watson is E.J. Ourso Professor of Business Analysis and Director of Strategic Initiatives in the College of Business at Louisiana State University. He received PhD and MS degrees in Industrial and Manufacturing Systems Engineering from The Pennsylvania State University. His current research areas are mainly in enterprise business systems, supply chain management, and IT transformation.

Theodore J. Williams

Purdue University
College of Engineering
West Lafayette, IN, USA
twilliam@purdue.edu

Chapter A.2

Theodore J. Williams is Professor Emeritus of Engineering, Purdue University. He received BS, MS, and PhD in Chemical Engineering from Pennsylvania State University and MS in Electrical Engineering from Ohio State University. Before joining Purdue, he was Senior Engineering Supervisor at Monsanto Chemical, St.Louis. He served as Chair of the IFAC/IFIP Task Force, Founding Chair of IFIP TC-5, President of AACC, ISA, and of AFIPS. Among his honors is the Sir Harold Hartley Silver Medal, the Albert F. Sperry Founder Award Gold Medal by ISA, and the Lifetime Achievement Award from ISA.

Alon Wolf

Technion Israel Institute of Technology
Faculty of Mechanical Engineering
Haifa, Israel
alonw@technion.ac.il

Chapter H.78

Alon Wolf earned all his academic degrees from the faculty of mechanical engineering at the Technion I.I.T (BS 1995, MSc 1998, PhD 2002). Then he joined the Institute for Computer Assisted Orthopedic Surgery (ICAOS) at the Western Pennsylvania Hospital and the Robotics Institute at Carnegie Mellon University. In 2006, Alon returned to Technion, where he directs the Biorobotics and Biomechanics Lab (BRML). His research interests range from the theoretical kinematics, mechanism design, and biomechanics to the applications in flexible mechanisms, medical robotic devices, biorobotics and rehabilitation systems.

Ning Xi

Michigan State University
Electrical and Computer Engineering
East Lansing, MI, USA
xin@egr.msu.edu

Chapter F.53

Ning Xi received his DSc degree in Systems Science and Mathematics from Washington University in St. Louis, MO in 1993. Dr. Xi is a fellow of IEEE. He has been elected as the President-Elect of IEEE Nanotechnology Council in 2008. His research interests include robotics, manufacturing automation, and micro/nano sensors as well as electronics.

Moshe Yerushalmy

MBE Simulations Ltd.
Petach Tikva, Israel
ymoshe@mbe-simulations.com

Chapter G.73

Moshe Yerushalmy is a leading management education visionary in developing ‘Serious Games’ for next generation learning solutions. His research and developing of virtual worlds has been used for managerial ‘Serious Games’. These games have been used in hundreds of events as well as in academia. He holds MBA degrees in Marketing(1994) and Information Technology (1987) from Tel Aviv University as well as BSc in Industrial Engineering from the Technion – Israel Institute of Technology (1980).

Sang Won Yoon

Purdue University
PRISM Center and School of Industrial Engineering
West Lafayette, IN, USA
yoon6@purdue.edu

Chapter J.94

Sang Won Yoon is a PhD candidate in the school of Industrial Engineering at Purdue University. He is a member of the PRISM Center. His research interests are in the areas of enterprise collaboration, production and operations management, information system integration, and decision support systems.

Stanislaw H. Żak

Purdue University
School of Electrical and Computer Engineering
West Lafayette, IN, USA
zak@purdue.edu

Chapter B.11

Dr. Stanislaw H. Żak received his PhD degree from the Warsaw University of Technology (Politechnika Warszawska). He is a co-author with E.K.P. Chong of *An Introduction to Optimization* whose third edition was published in 2008. He is the author of *Systems and Control* published in 2003.
